23.2.3.1 Determining Loop Resolution

As an example, consider an application that requires high resolution of HRP = 62.5 ns, and loop resolution of LRP = 8 µs, and needs at least 250 time slots for the N2HET application program.

Assuming VCLK2 = 32 MHz, the following shows which divide-by rates and which value in the Prescale Factor Register (HETPFR) is required for the above requirements:

$$hr = 2 \rightarrow HRP = \frac{hr}{VCLK2} = \frac{2}{32MHz} = 62.5ns$$

$$lr = 128 \rightarrow lr \times HRP = 128 \times 62.5ns = 8\ \mu s$$

$$ts = hr \times lr = 2 \times 128 = 256$$

$$hr = 2, lr = 128 \rightarrow HETPFR[31:0] = 0x00000701 \quad (29)$$

In the example above, if the loop resolution period needs to decrease from 8 µs to 4 µs, then only 128 time slots will be available for program execution. The program may need to be restructured as suggested in Section 23.2.1.6.

23.2.3.2 The 7-Bit HR Data Field

The instruction execution examples of ECMP (Section 23.2.5.9), MCMP (Section 23.2.5.10), PCNT (Section 23.2.5.12), PWCNT (Section 23.2.5.11), and WCAP (Section 23.2.5.13) show that the 7-bit HR data field can generate or measure high resolution delays (HR delay) relative to the start of an LRP within one N2HET loop LRP. The last section showed that:

LRP = lr × HRP

There are lr high resolution clock periods (HRP) within the N2HET loop resolution clock period (LRP). If lr = 128 then the HR delay can range from 0 to127 HRP clocks within LRP and all 7 bits of the HR data field are needed. Instead of being limited to measuring and triggering events based on the loop resolution clock period (LRP) the HR extension allows measurements and events to be described in terms fractions of an LRP (down to 1/128 of an LRP). The only limitation is that a maximum of one HR delay can be specified per pin during each loop resolution period.

Table 23-6 shows which bits of the HR data field are not used by the high resolution IO structures if lr is less than 128. In this case the non-relevant bits (LSBs) of the HR data fields will be one of the following:

- Written as 0 for HR capture (for PCNT, WCAP)
- Or interpreted as 0 for HR compare (for ECMP, MCMP. PWCNT)

Table 23-6. Interpretation of the 7-Bit HR Data Field

Loop Resolution Prescale divide rate (lr)	Bits of the HR data field [1]							HRP Cycles delay range
	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]	
1	X X X X X X X							0
2	1/2	X X X X X X						0 to 1
4	1/2	1/4	X X X X X					0 to 3
8	1/2	1/4	1/8	X X X X				0 to 7
16	1/2	1/4	1/8	1/16	X X X			0 to 15
32	1/2	1/4	1/8	1/16	1/32	X X		0 to 31
64	1/2	1/4	1/8	1/16	1/32	1/64	X	0 to 63
128	1/2	1/4	1/8	1/16	1/32	1/64	1/128	0 to 127

(1) X = Non-relevant bit (treated as '0')

Copyright © 2018, Texas Instruments Incorporated

23.2.3.2.1 Example:

Prescale Factor Register (HETPFR) = 0x0300

—> lr = 8 —> LRP = 8 × HRP

Assumption: HR data field = 0x50 = 1010000b

lr = 8 —> Bits D[3:0] are ignored —> HR delay = 101b = 5 HRPs

or by using the calculation with weight factors:

HR Delay
= lr · (D[6] · 1/2 + D[5] · 1/4 + D[4] · 1/8 + D[3] · 1/16 + D[2] · 1/32 + D[1] · 1/64 + D[0] · 1/128)
= 8 · (1 · 1/2 + 0 · 1/4 + 1 · 1/8 + 0 · 1/16 + 0 · 1/32 + 0 · 1/64 + 0 · 1/128)
= 5 HRPs

23.2.4 Host Interface

The host interface controls all communications between timer-RAM and masters accessing the N2HET RAM. It includes following components:

23.2.4.1 Host Accesses to N2HET RAM

The host interface supports the following types of accesses to N2HET RAM:

- Read accesses of 8, 16, or 32 bits
- Read accesses of 64-bits that follow the shadow register sequence described in Section 23.2.4.2.
- Write accesses of 32 bits

Writes of 8 or 16 bits to N2HET RAM by an external host are not supported.

23.2.4.2 64-bit Read Access

The consecutive read of a control field CF(n) and a data field DF(n) of the same instruction (n) performed by the same master (for example, CPU, DMA, or any other master) is always done as a simultaneous 64-bit read access. This means that at the same time CF(n) is read, DF(n) is loaded in a shadow register. So the second access will read DF(n) from the shadow register instead of the N2HET RAM.

In general a 64-bit read access of one master could be interrupted by a 64-bit read access of another master. A total of three shadow registers are available. Therefore up to three masters can perform 64-bit reads in an interleaved manner (Master1 CF, Master2 CF, Master3 CF, Master1 DF, Master2 DF, Master3 DF).

If all three shadow registers are activated and a 4th master performs a CF or DF read it will result in an address error and the RAM access will not happen. Other access types by a fourth master (reads from the PF field or writes to any of the fields) will occur because these access types do not require an available shadow register resource to complete.

23.2.4.3 Automatic Read Clear Feature

The N2HET provides a feature allowing to automatically clear the data field immediately after the data field is read by the external host CPU (or DMA). This feature is implemented via the *control bit*, which is located in the control field (bit C26). This is a static bit that can be used by any instruction, and specified in the N2HET program by adding the option (control = ON) to the N2HET instruction. The automatic read clear feature works for both 32 and 64 bit reads that follow the sequence described in Section 23.2.4.2.

When the host CPU reads the data field of that instruction, the current data value is returned to the host CPU but the field is cleared automatically as a side effect of the read. In case the master reads data from an instruction currently executing, any new capture result is stored and this takes priority over the automatic read clear feature, so that the new capture result is not lost.

Copyright © 2018, Texas Instruments Incorporated

As an example of where the automatic read clear feature is useful, consider the PCNT instruction. If this instruction is configured for automatic read clear, then when the host CPU reads the PCNT data field it will be cleared automatically. The host CPU can then poll the PCNT data field again, and as long as the field returns a value of zero the host CPU program knows a new capture event has not occurred. If the data field were not cleared, it would be impossible for the host CPU to determine whether the data field holds data from the previous capture event, or if it happens to be data from a new capture event with the same value.

23.2.4.4 Emulation Mode

Emulation mode, used by the software debugger, is specified in the global configuration register. When the host CPU debugger hits a breakpoint, the CPU sends a suspend signal to the modules. Two modes of operation are provided: suspend and ignore suspend.

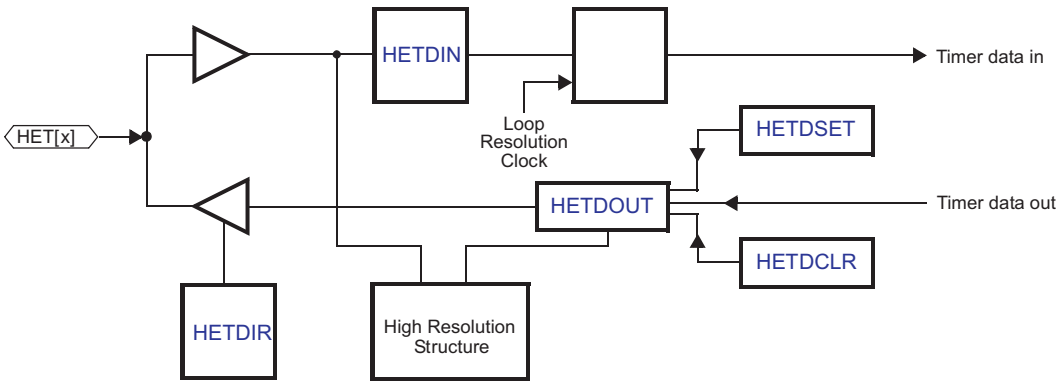
- Suspend

When a suspend is issued, the timer operation stops at the end of the current timer instruction. However, the CPU accesses to the timer RAM or control registers are freely executed.

- Ignore suspend

The timer RAM ignores the suspend signal and operates real time as normal.

23.2.4.5 Power-Down



After setting the turn-off bit in the Global Configuration Register (HETGCR), it is required to delay until the end of the timer program loop before putting the N2HET in power-down mode. This can be done by waiting until the N2HET Current Address (HETADDR) becomes zero, before disabling the N2HET clock source in the device's Global Clock Module (GCM).

23.2.5 I/O Control

The N2HET has up to 32 pins. Refer to device specific data sheets for information concerning the number of N2HETIO available. All of the N2HET pins available are programmable as either inputs or outputs.

These 32 I/Os have an identical structure connected to pins HET[31] to HET[0]. See Figure 23-8 for an illustration of the I/O control. In addition all 32 I/Os have a special HR structure based on the HR clock. This structure allows any N2HET instruction to use any of these I/Os with an accuracy of either loop resolution or high resolution accuracy.

Figure 23-8. I/O Control

Pins N2HET [31] to N2HET [0] can be used by the CPU as general-purpose inputs or outputs using the N2HET Data Input Register (HETDIN) for reading and N2HET Data Output Register (HETDOUT), N2HET Data Set Register (HETDSET) or N2HET Data Clear Register (HETDCLR) for writing, depending on the type of action to perform. The N2HET pins used as general-purpose inputs are sampled on each VCLK2 period.

Copyright © 2018, Texas Instruments Incorporated

23.2.5.1 Using General-Purpose I/O Data Set and Clear Registers

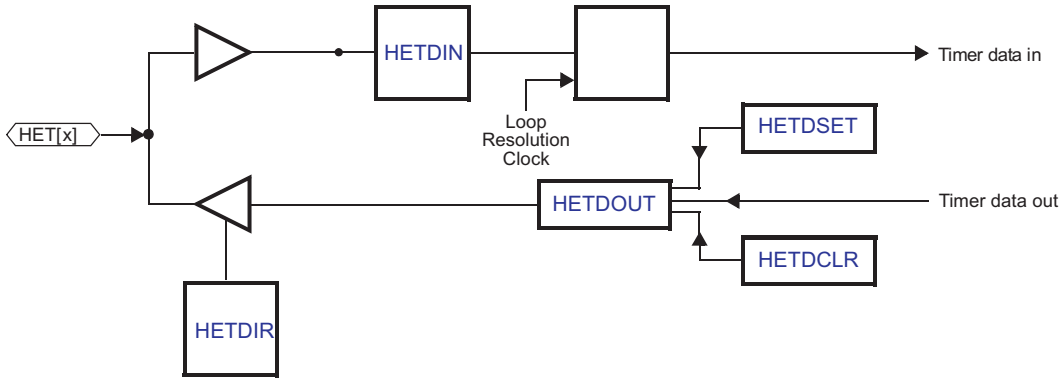
The N2HET Data Clear Register (HETDCLR) and N2HET Data Set Register (HETDSET) can be used to minimize the number of accesses to the peripheral to modify the output register and output pins. When the application needs to set or to reset some N2HET pins without changing the value of the others pins, the first possibility is to read N2HET Data Output Register (HETDOUT), modify the content (AND, OR, and so on), and write the result into N2HET Data Output Register (HETDOUT). However, this read-modify-write sequence could be interrupted by a different function modifying the same register which will result in a data coherency problem.

Using the N2HET Data Set Register (HETDSET) or N2HET Data Clear Register (HETDCLR), the application program must write the mask value (same mask value for the first option) to the register to set or reset the desired pins. Any bits written as 0 to HETDSET and HETDCLR are left unchanged, which avoids the possible coherency problem of the read-modify-write approach.

```
Coding Example (C program): Set pins using the 2 methods.

unsigned int MASK;                              /* Variable that content the bit mask  */
volatile unsigned int *HETDOUT,*HETDSET;        /* Pointer to HET registers            */
...
*HETDOUT = *HETDOUT | MASK;                     /* Read-modify-write of HETDOUT        */
*HETDSET = MASK;                                /* Set the pin without reading HETDOUT */
```

23.2.5.2 Loop Resolution Structure



The N2HET uses the pins N2HET [31:0] as input and/or output by the way of the instruction set. Actually, each pin could monitor the N2HET program or could be monitored by the N2HET program. By using the I/O register of the N2HET, the CPU is able to interact with the N2HET program flow.

When an action (set or reset) is taken on a pin by the N2HET program, the N2HET will modify the pin at the rising edge of the next loop resolution clock.

When an event occurs on a N2HET I/O pin, it is taken into account at the next rising edge of the loop resolution clock.

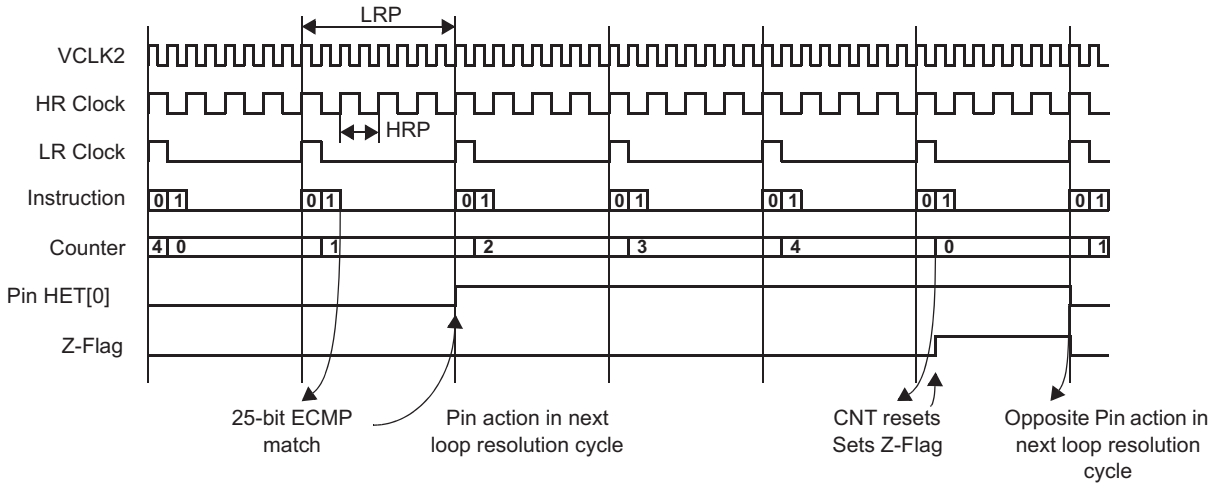
The structure of each pin is shown in Figure 23-9.

Figure 23-9. N2HET Loop Resolution Structure for Each Bit

The example in Figure 23-10 shows a simple PWM generation with loop resolution accuracy. The corresponding program is:

```
HETPFR[31:0] register = 0x201 --> lr=4 and hr=2 --> ts = 8

N2HET Program:



L00  CNT   { next= L01, reg=A, irq=OFF, max = 4 }
L01  ECMP  { next= L00, cond_addr= L00, hr_lr=LOW, en_pin_action=ON, pin=0,
             action=PULSEHI, reg=A, irq=OFF, data= 1, hr_data = 0x0 }

; 25 bit compare value is 1 and the 7-bit HR compare value is 0
```

Copyright © 2018, Texas Instruments Incorporated

The CNT and ECMP instructions are executed once each loop resolution cycle. When the CNT instruction is executed, the specified register (A) and the CNT instruction data field are both incremented by one. Next the ECMP is executed and the data field of the ECMP is compared with the specified register (A). If both values match, then the pin action (PULSEHI in this case) will be performed in the next loop resolution cycle. The CNT continues incrementing each loop resolution cycle. When the data field overflows (max + 1), then the Z-flag is set by the CNT instruction. In the next loop resolution cycle, the Z-flag is evaluated and the opposite pin action is performed if it is set. The Z-flag will only be active for one loop resolution cycle.

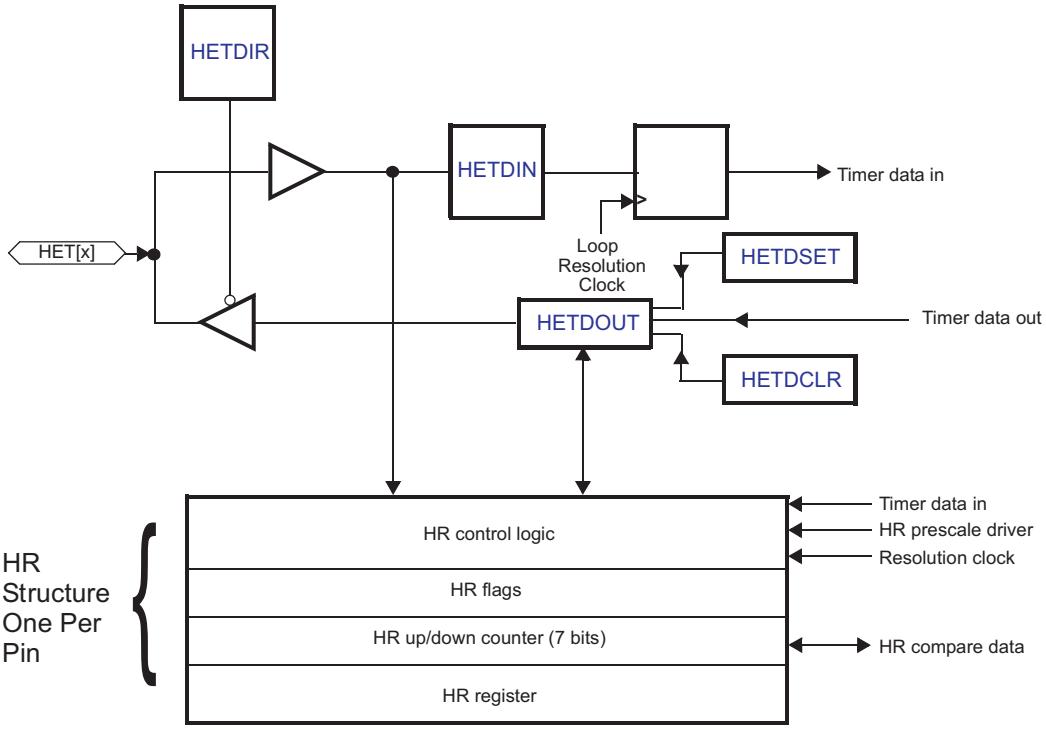
Figure 23-10. Loop Resolution Instruction Execution Example

23.2.5.3 High Resolution Structure

All 32 I/Os provide the HR structure based on the HR clock. The HR clock frequency is programmed through the Prescale Factor Register (HETPFR). In addition to the standard I/O structure, all pins have HR hardware so that these pins can be used as HR input captures (using the HR instructions PCNT or WCAP) or HR output compares (using the HR instructions ECMP, MCMP, or PWCNT).

All five HR instructions (PCNT, WCAP, ECMP, MCMP, and PWCNT) have a dedicated hr_lr bit (high resolution/low resolution; program field bit 8) allowing operation either in HR mode or in standard resolution mode by ignoring the HR field. By default, the hr_lr bit value is 0 which implies HR operation mode. However, setting this bit to one allows the use of several HR instructions on a single HR pin. Only one instruction is allowed to operate in HR mode (bit cleared to 0), but the other instructions can be used in standard resolution mode (bit set to 1).

Copyright © 2018, Texas Instruments Incorporated



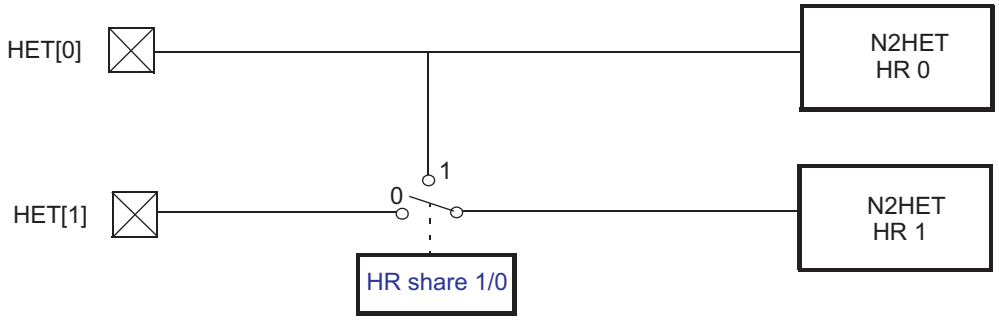
23.2.5.4 HR Block Diagram

Each time an HR instruction is executed on a given pin, the HR structure for that pin is programmed and synchronized to the next loop-resolution cycle (which HR function to perform and on which edges it should take an action) with the information given by the instruction. The HR structure for each pin decodes the pin select field of the instruction and programs its HR structure if it matches.

NOTE: For each N2HET pin, only one instruction specifying a high resolution operation (hr_lr = HIGH) is allowed to execute per loop resolution period. This includes any instructions where (hr_lr = HIGH) but (en_pin_action = OFF).

The first high resolution instruction that executes and specifies a particular pin locks out subsequent high resolution instructions from operating on the same pin until the end fo the current loop resolution period.

Figure 23-11. HR I/O Architecture



Copyright © 2018, Texas Instruments Incorporated

23.2.5.5 HR Structures Sharing (Input)

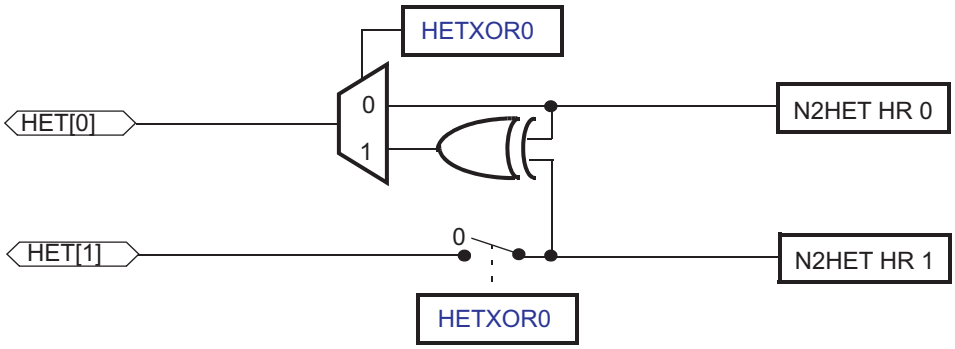
The HR Share Control Register (HETHRSH) allows two HR structures to share the same pin **for input capture only**. If these bits are set, the HR structures N and N+1 are connected to pin N. In this structure, pin N+1 remains available for general-purpose input/output. See Figure 23-12.

Figure 23-12. Example of HR Structure Sharing for N2HET Pins 0/1

The following program gives an example how the HR share feature (HET[0] HR structure and HET[1] HR structure shared) can be used for the PCNT instruction:

```
L00 PCNT { next=L01, type=rise2fall, pin=0 }
L01 PCNT { next=L00, type=fall2rise, pin=1 }
```

The HET[1] HR structure is also connected to the HET[0] pin. The L00_PCNT data field is able to capture a high pulse and the L01_PCNT captures a low pulse on the **same** pin (N2HET [0] pin).



Copyright © 2018, Texas Instruments Incorporated

23.2.5.6 AND / XOR-shared HR Structure (Output)

Usually the N2HET design allows only one HR structure to generate HR edges on a pin configured as output pin. The HETXOR register allows a logical XOR of the output signals of two consecutive HR structures N (even) and N+1 (odd). See Figure 23-13. In this way, it is possible to generate pulses smaller than the loop resolution clock since both edges can be generated by two independent HR structures. This is especially required for symmetrical PWM. See Figure 23-14.

The hardware provides a XOR gate that is connected to the outputs of the HR structure of two consecutive pins. In this structure, pin N+1 remains available for general-purpose input/output.

Figure 23-13. XOR-shared HR I/O

The following N2HET program gives an example for **one** channel of the symmetrical PWM. The generated timing is given in Figure 23-14.

```
MAXC .equ 22
A_   .equ 0  ; HR structure HR0
B_   .equ 1  ; HR structure HR1

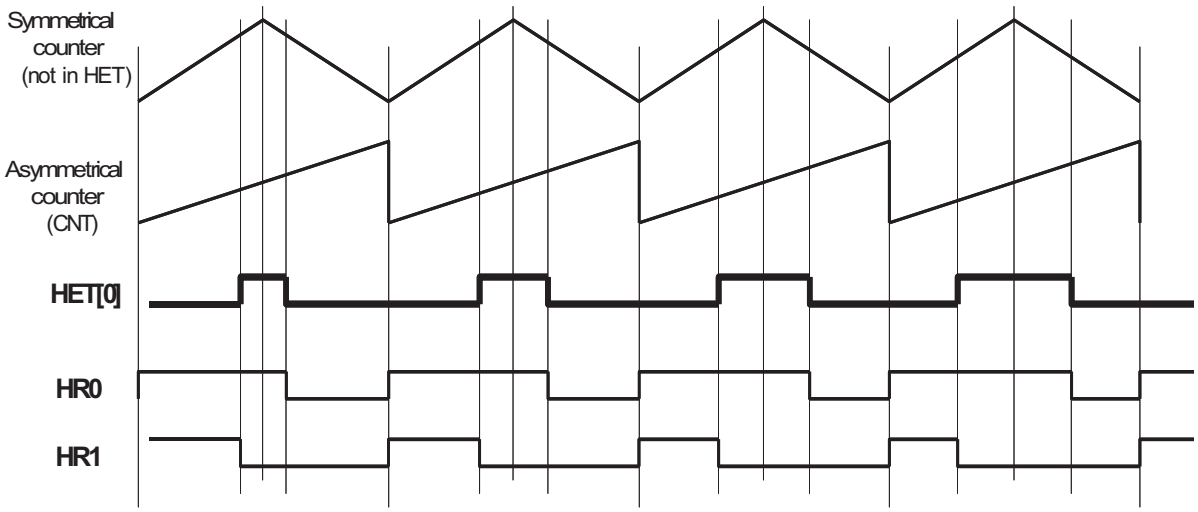
CN CNT   { next=EA, reg=A, max=MAXC }

EA ECMP  { next=EB, cond_addr=MA, hr_lr=HIGH, en_pin_action=ON, pin=A_,
           action=PULSELO, reg=A, data=17, hr_data=115 }

MA MOV32 { next=EB, remote=EA, type=IMTOREG&REM, reg=NONE, data=17, hr_data=19 }

EB ECMP  { next=CN, cond_addr=MB, hr_lr=HIGH, en_pin_action=ON, pin=B_,
           action=PULSELO, reg=A, data=5, hr_data=13 }

MB MOV32 { next=CN, remote=EB, type=IMTOREG&REM, reg=NONE, data=5, hr_data=13 }
```



N2HET Settings and output signal calculation for this example program:

- Pin HET[0] and HET[1] are XOR-shared.
- HETPFR[31:0] register = 0x700: lr=128, hr=1, time slots ts = 128
- PWM period (determined by CNT_max field) = (22+1) · LRP = 2944 HRP
- Length of high pulse of (HET[0] XOR HET[1]) =
  LH = (17·LRP+115·HRP) - (5·LRP+13·HRP)
  With lr=128 there is LRP = 128 · HRP, so
  LH = (2291 - 653) · HRP = 1638 HRP
- Duty cycle = DC = LH / PWM_period = 1638 HRP / (2944·HRP) = 55.6 %

Copyright © 2018, Texas Instruments Incorporated

Figure 23-14 graphically shows the implementation of the XOR-shared feature. The first 2 waveforms (symmetrical counter and CNT) show a symmetric counter and asymmetric counter. The symmetric counter is shown only to highlight the axis of symmetry and is not implemented in the N2HET. The asymmetric counter, which is implemented with a CNT instruction, needs to be set to the period of the symmetric counter. The next two waveforms (HR [0] and HR [1]) show the output of the HR structures, which are the inputs for the XOR gate to create the PWM output on pin HET[0]. Notice that the pulses of signal HET[0] are centered about the axis of symmetry.

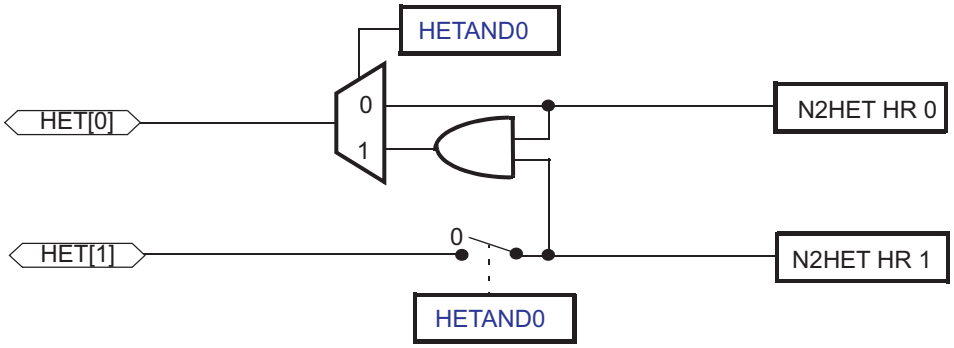


Figure 23-14. Symmetrical PWM with XOR-sharing Output

As an alternative, HR structures may be shared using a logical AND function to combine the effects of the pin structures. The HETAND allows sharing two consecutive HR structures N (even) and N+1 (odd). See Figure 23-15. In this structure, pin N+1 remains available for general-purpose input/output.

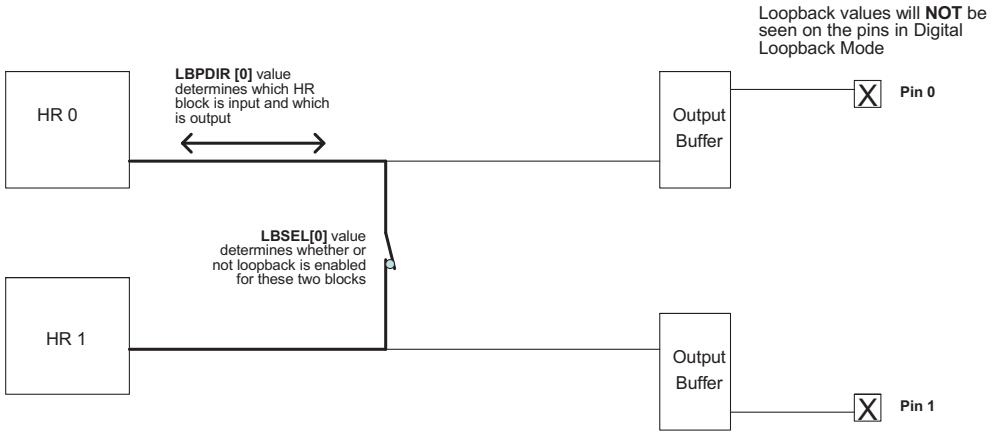
NOTE: Setting both the HETAND bit and HETXOR bits at the same time for a given pair of N2HET pins is not supported, must be avoided by the application program.

Figure 23-15. AND-shared HR I/O

Copyright © 2018, Texas Instruments Incorporated

23.2.5.7 Loop Back Mode

The loop back feature can be used by the application to monitor an N2HET output signal. For example, if a PWM is generated by HR structure 0, then a PCNT instruction assigned to HR structure 1 can measure back the pulse length or periods of the PWM output signal.



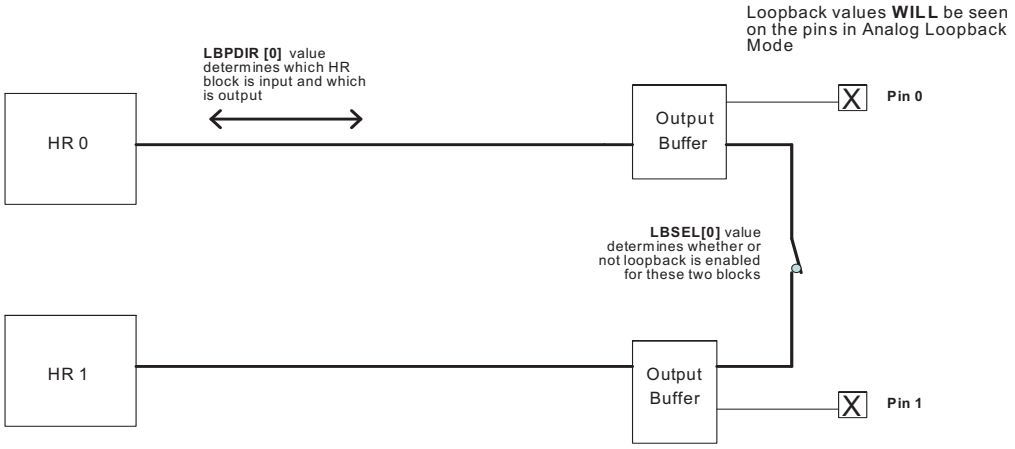
Loopback mode is activated between two high resolution structures by setting LBPSEL[x] to 1 in the HETLBPSEL register for the corresponding structure pair. The **direction** of the loopback between the two structures in the structure pair is determined by the value of LBPDIR[x] in the HETLBPDIR Register.

For example, if bit LBPSEL[0] is set to 1, then HR structures 0 and 1 will be internally connected in loop back mode. If bit LBPDIR[0] is set to 0, then structure 0 will be the input and structure 1 will be the output.

Digital Loopback

Digital loopback mode is enabled by setting LBPTYPE[x] to 0 in the HETLBPSEL register for the corresponding structure pairs. In digital loopback mode, the structure pairs are connected directly and the output buffers are bypassed. Therefore, the loopback values will NOT be seen on the corresponding pins. Figure 23-16 shows an example of digital loopback between structures HR0 and HR1. LBSEL[0] has been set to 1 to enable loopback between the two structures. LBTYPE[0] has been set to 0 to select digital mode for the loopback pair. The LPBDIR[0] value will determine the direction of the loopback by selecting which of the HR blocks is output, and which is input. The bold lines show the digital loopback path.

Figure 23-16. HR0 to HR1 Digital Loopback Logic: LBTYPE[0] = 0



Copyright © 2018, Texas Instruments Incorporated

Analog Loopback

Analog loopback mode is enabled by setting LBPTYPE[x] to 1 in the HETLBPSEL register for the corresponding structure pairs. In analog loopback mode, the structure pairs are connected outside of the output buffers. Therefore, the loopback values WILL be seen on the corresponding pins. Figure 23-17 shows an example of analog loopback between structures HR0 and HR1. LBSEL[0] has been set to 1 to enable loopback between the two structures. LBTYPE[0] has been set to 1 to select analog mode for the loopback pair. The LPBDIR[0] value will determine the direction of the loopback by selecting which of the HR blocks is output, and which is input. The bold lines show the analog loopback path.

Figure 23-17. HR0 to HR1 Analog Loop Back Logic: LBTYPE[0] = 1

Note:

- The loop back direction can be selected independent of the HETDIR register setting.
- The pin that is not driven by the N2HET output pin actions can still be used as normal GIO pin.

23.2.5.8 Edge Detection Input Timing

There are several timing requirements for input signals in order to be captured correctly by N2HET. Figure 23-18 illustrates these requirements, with min and max values described in Table 23-7 (Loop Resolution) and Table 23-8 (High Resolution).

Figure 23-18. N2HET Input Edge Detection

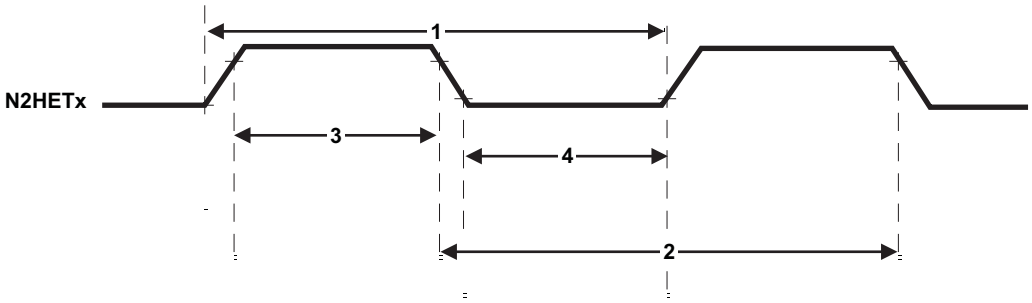

Table 23-7. Edge Detection Input Timing for Loop Resolution Instructions

Parameter #	Description	min	max
1	Input Signal Period, rising edge to rising edge	> 2 (hr) (lr) $t_{c(VCLK2)}$	< 2^{25} (hr) (lr) $t_{c(VCLK2)}$
2	Input Signal Period, falling edge to falling edge		
3	Input Signal, high phase	> (hr) (lr) $t_{c(VCLK2)}$	
4	Input Signal, high phase		

Table 23-8. Edge Detection Input Timing for High Resolution Instructions

Parameter #	Description	min	max
1	Input Signal Period, rising edge to rising edge	> (hr) (lr) $t_{c(VCLK2)}$	< 2^{25} (hr) (lr) $t_{c(VCLK2)}$
2	Input Signal Period, falling edge to falling edge		
3	Input Signal, high phase	> 2 (hr) $t_{c(VCLK2)}$	
4	Input Signal, high phase		

These are the N2HET architectural limitations. Actual limitations will be slightly different due to on chip routing and IO buffer delays, usually by several nanoseconds. Be sure to consult the device datasheet for actual timings that apply to that device. Also, certain devices place additional restrictions on which pins support the high resolution timings of Table 23-8, if present these additional limitations will also be called out in the device datasheet.

Note that the max limit in Table 23-7 and Table 23-8 is based on the counter range of a single N2HET instruction. The max value could be extended by employing an additional N2HET instruction to keep track of counter overflows of the input counter / capture instruction.

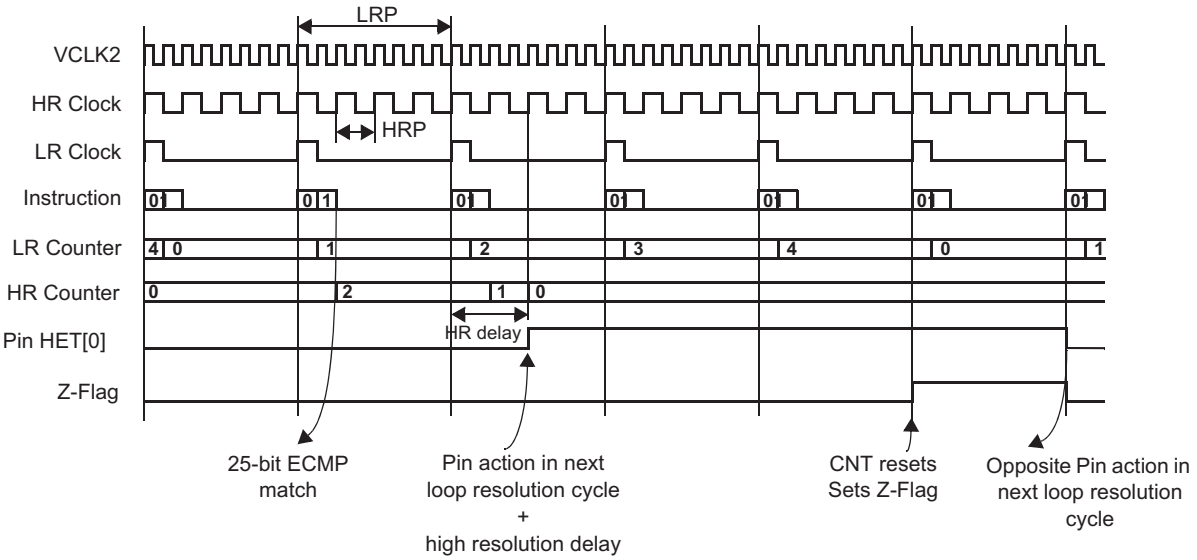
23.2.5.9 PWM Generation Example 1 (in HR Mode)

The following example shows how an ECMP instruction works in high resolution mode. The example assumes a VCLK2 of 32 MHz and the following values for the prescale divide rates (hr and lr), number of time slots (ts), high and loop resolution period (HRP and LRP):

hr = 2, lr = 4, ts = hr × lr = 8

HRP = hr / VCLK2 = 2 / 32 MHz = 62.5 ns

LRP = (hr × lr) / VCLK2 = 8 / 32 MHz = 250 ns



With ts = 8, there are eight time slots available for the program execution, which in this case will consist of one CNT and one ECMP instruction as shown below. The data field of the ECMP instruction is the 32-bit compare value, whereby the lower 7 bits represent the high resolution compare field.

Copyright © 2018, Texas Instruments Incorporated

When the 25-bit (loop resolution) compare matches, the HR compare value will be loaded from the 7 lower bits of the instruction data field to the HR counter. At the next loop resolution clock, the HR counter will count down at the HR clock frequency and perform the pin action when it reaches zero.

In the example illustrated by Figure 23-19, the 25-bit compare value is 1 and the 7-bit HR compare value is 2. According to Section 23.2.3.2, depending on the loop resolution divide rate (lr), only certain bits of the 7-bit HR compare value are valid. In this example only the upper 2 bits (D[6:5]) are taken into account. The example program below has a setting of hr_data = 100000b. Shifting this value right by 5 bits, results in 10b which equals the two HR clock cycles delay mentioned above.

Figure 23-19. ECMP Execution Timings

```
HETPFR[31:0] register = 0x201 --> lr=4 and hr=2 --> ts = 8

N2HET Program:

L00   CNT   { next= L01, reg=A, irq=OFF, max = 4 }
L01   ECMP  { next= L00, cond_addr= L00, hr_lr=HIGH, en_pin_action=ON, pin=0,
              action=PULSEHI, reg=A, irq=OFF, data= 1, hr_data = 0x40 }

; 25 bit compare value is 1 and the 7-bit HR compare value is 2
; (Because of lr=4 the D[4:0] of the 7-bit HR field are ignored )
```

NOTE: ECMP Opposite Actions

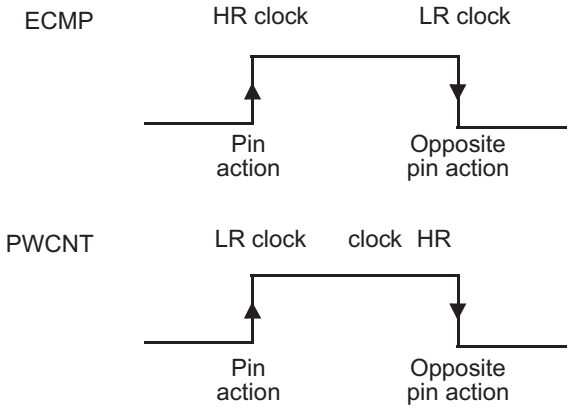
ECMP opposite pin actions are always synchronized to the loop resolution clock.

Changing the duty cycle of a PWM generated by an ECMP instruction, can lead to a missing pulse if the data field of the instruction is updated directly. This can happen when it is changed from a high value to a lower value while the CNT instruction has already passed the new updated lower value. To avoid this a synchronous duty cycle update can be performed with the use of an additional instruction (MOV32). This instruction is only executed when the compare of the ECMP matches. For this the cond_addr of the ECMP needs to point to the MOV32. On execution of the MOV32, it moves its data field into the data field of the ECMP. The update of the duty cycle has to be made to the MOV32 data field instead of the ECMP data field.

Copyright © 2018, Texas Instruments Incorporated

23.2.5.10 PWM Generation Example 2 (in HR Mode)

The MCMP instruction can also be used in HR mode. In this case operation is exactly the same as for the ECMP instruction except that the 25-bit low resolution is now the result of a magnitude compare (greater or equal) rather than an equality compare. When the 25-bit (loop resolution) magnitude compare matches, the HR compare value will be loaded from the 7 lower bits of the instruction data field to the HR counter. At the next loop resolution clock, the HR counter will count down at the HR clock frequency and perform the pin action when it reaches zero.



The MCMP instruction avoids the missing pulse problem of the ECMP instruction (see previous example), however the duty cycle of the signal might not be exact for one PWM period. The benefit of the MCMP is that it avoids adding another instruction to do the duty cycle update synchronously.

23.2.5.11 Pulse Generation Example (in HR Mode)

The PWCNT instruction may also be used in HR mode to generate pulse outputs with HR width. It generates a single pulse when the data field of the instruction is non-zero. It remains at the opposite pin action when the data field is zero.

The PWCNT instruction operates conversely to the ECMP instruction. See Figure 23-20. For PWCNT, the opposite pin action is synchronous with the HR clock and for ECMP the pin action is synchronous with the HR clock. The PWCNT pin action is synchronous with the loop resolution clock.

Figure 23-20. High/Low Resolution Modes for ECMP and PWCNT

23.2.5.12 Pulse Measurement Example (in HR Mode)

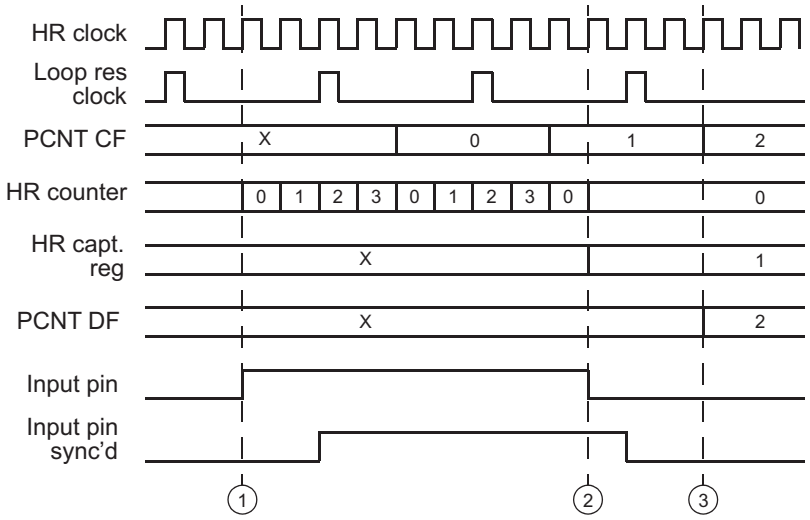
The PCNT instruction captures HR measurement of the high/low pulse time or periods of the input. As shown in Figure 23-21, at marker (1) the input goes HIGH and the HR counter immediately begins to count. The counter increments and rolls over until the falling edge on the input pin, where it captures the counter value into the HR capture register (marker (2)). The PCNT instruction begins counting when the synchronized input signal goes HIGH and captures both the 25-bit data field and the HR capture register into RAM when the synchronized input falls (marker (3)).

NOTE: The HR capture value written into RAM is shifted appropriately depending on the loop resolution prescale divide rate (lr). (See also Section 23.2.3.2).

Copyright © 2018, Texas Instruments Incorporated

Figure 23-21 shows what happens when the capture edge arrives *after* the HR counter overflows. This causes the incremented value to be captured by the PCNT instruction.

Figure 23-21. PCNT Instruction Timing (With Capture Edge After HR Counter Overflow)



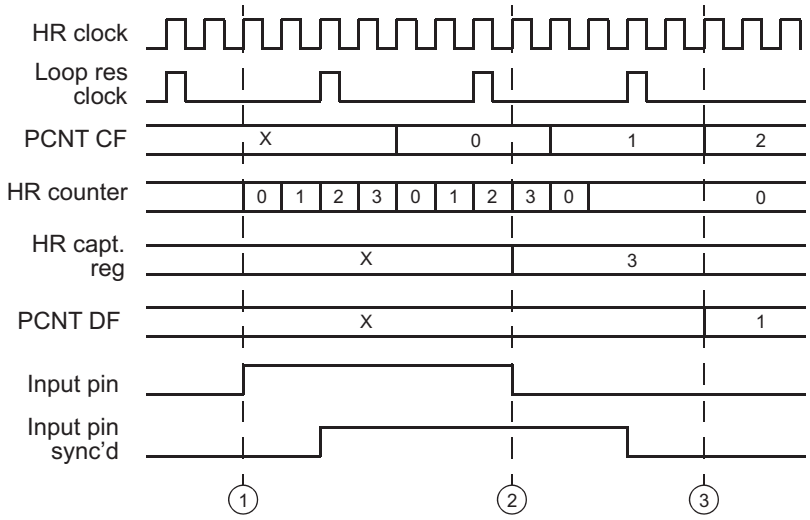


Figure 23-22 shows what happens when the capture edge arrives *before* the HR counter overflows. This causes the non-incremented value to be captured by the PCNT instruction.

Figure 23-22. PCNT Instruction Timing (With Capture Edge Before HR Counter Overflow)

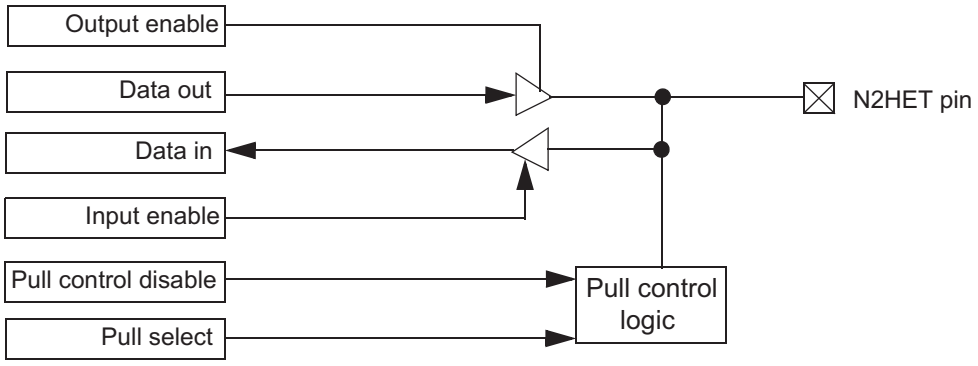
23.2.5.13 WCAP Execution Example (in HR Mode)

The HR capability is enabled for WCAP, if its hr_lr bit is zero. In this case the HR counter is always enabled and is synchronized with the resolution loop. When the specified edge is detected, the current value of the HR counter is captured in the HR capture register and written into the RAM after the next WCAP execution. The WCAP instruction effectively time stamps the free running timer saved in a register (for example, register A shown in Figure 23-23).

Figure 23-23. WCAP Instruction Timing

```
HETPFR_register = 0x0200 --> lr = 4, hr = 1, ts = 4

N2HET Program:



L00 CNT  {reg=A, max=01ffffffh}
L01 WCAP {next=L00, cond_addr=L00, hr_lr=high, reg=A, event= FALL, pin=0,
          data=0}
```

In the example, the WCAP is configured to capture the counter when a **falling** edge occurs. The WCAP data field (WCAP_DF) is updated in the loop succeeding the loop in which the edge occurred. The WCAP instruction evaluates an edge by comparing its Previous bit with the sync'd input signal. In Figure 23-23, the current value of the counter (4) is captured to WCAP_DF[31:7] and the value of the HR capture register (2) is transferred to the valid bits (according the lr prescaler) of WCAP_DF[6:0]. Therefore, in the example 0x0240 is captured in WCAP_DF[31:0].

23.2.5.14 I/O Pull Control Feature

Figure 23-24. I/O Block Diagram Including Pull Control Logic

The following apply if the device is under reset:

- Pull control: The reset pull control on the pins is enabled and a pulldown is configured.
- Input buffer: The input buffer is enabled.
- Output buffer: The output buffer is disabled.

The following apply if the device is out of reset:

- Pull control: The pull control is enabled by clearing the corresponding bit in the N2HET Pull Disable Register (HETPULDIS). In this case, if the corresponding bit in the N2HET Pull Select Register (HETPSL) is set, the pin will have a pull-up; if the bit in the N2HET Pull Select Register (HETPSL) is cleared, the pin will have a pull-down. If the bit in the N2HET Pull Disable Register (HETPULDIS) is set, there is no pull-up or pull-down on the pin.
- Input buffer: The input buffer is disabled only if the pin direction is set to input AND the pull control is disabled AND pull down is selected as the pull bias. In all other cases, the input buffer is enabled.

NOTE: The pull-disable logic depends on the pin direction. If the pin is configured as output, then the pulls are disabled automatically. If the pin is configured as input, the pulls are enabled or disabled depending on the pull disable register bit.

- Output buffer: A pin can be driven as an output pin if the corresponding bit in the N2HET Direction Register (HETDIR) is set AND the open-drain feature (N2HET Open Drain Register (HETPDR)) is not enabled. See Section 23.2.5.15 for more details.

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 23-9. When an input buffer is disabled, it appears as a logic low to on-chip logic.

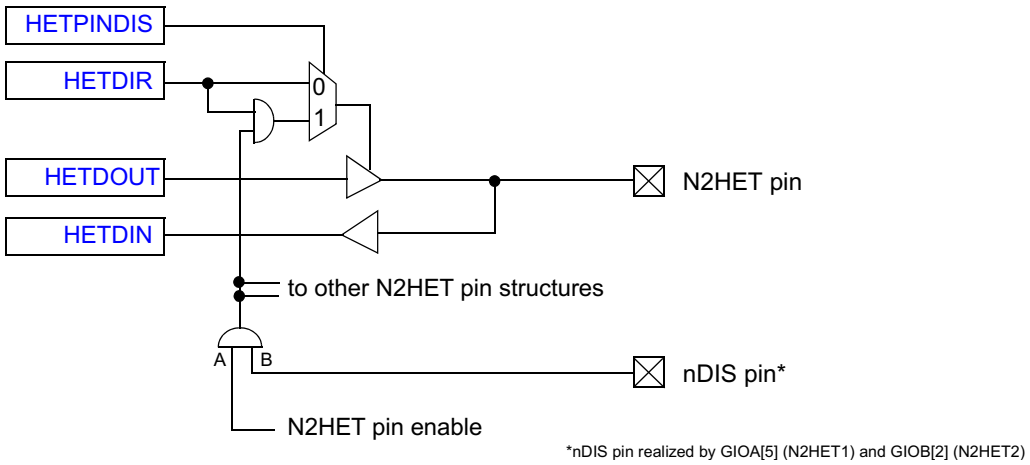
Table 23-9. Input Buffer, Output Buffer, and Pull Control Behavior

Device under Reset?	Pin Direction (DIR)[1]	Pull Disable (PULDIS)[1]	Pull Select (PULSEL)[1]	Pull Control	Output Buffer	Input Buffer
Yes	X	X	X	Enabled	Disabled	Enabled
No	0	0	0	Pull down	Disabled	Enabled
No	0	0	1	Pull up	Disabled	Enabled
No	0	1	0	Disabled	Disabled	Disabled
No	0	1	1	Disabled	Disabled	Enabled
No	1	X	X	Disabled	Enabled	Enabled

(1) X = Don't care

23.2.5.15 Open-Drain Feature

The following apply if the open-drain feature is enabled on a pin, that is, the corresponding bit in the N2HET Open Drain Register (HETPDR) is set:



- Output buffer is enabled if a low signal is being driven internally to the pin.
- The output buffer is disabled if a high signal is being driven internally to the pin.

23.2.5.16 N2HET Pin Disable Feature

This feature is provided for the safe operation of systems such as power converters and motor drives. It can be used to inform the monitoring software of motor drive abnormalities such as over-voltage, over-current, and excessive temperature rise.

Table 23-10 shows the conditions for the output buffer to be enabled/disabled.

Figure 23-25. N2HET Pin Disable Feature Diagram

Copyright © 2018, Texas Instruments Incorporated

Table 23-10. N2HET Pin Disable Feature

HETPINDIS.x	nDIS Pin (Input)	HET_PIN_ENA (HETGCR.24)	HETDIR.x	Output Buffer
0	X	X	0	Disabled
0	X	X	1	Enabled
1	0	X	0	Disabled
1	0	X	1	Disabled
1	1	X	0	Disabled
1	1	0	1	Disabled
1	1	1	1	Enabled

An interrupt capable device I/O pin can share the same pin as the N2HET nDIS signal. Normally GIOA[5] serves as nDIS for N2HET1 and GIOB[2] as nDIS for N2HET2. Check the device datasheet for the actual implementation. Sharing a pin with a GIO pin that is Interrupt capable allows the N2HET nDIS input to also generate an interrupt to the CPU. An active low level on nDIS is intended to signal an abnormal situation as described above. All N2HET pins, which are selected with the N2HET Pin Disable Register (HETPINDIS), will be put in the high-impedance state by hardware immediately after the nDIS signal is pulled low. At this time a CPU interrupt is issued, if it is enabled in the GIO pin logic.

The bit HET_PIN_ENA is automatically cleared in the failure condition and this state remains as long as the software explicitly sets the bit again. The steps to do this are:

- Software detects, by reading the HETDIN register of the GIO pin, that the level on nDIS is inactive (high).
- Software sets bit HET_PIN_ENA to deactivate the high impedance state of the pins.

23.2.6 Suppression Filters

Each N2HET pin is equipped with a suppression filter. If the pin is configured as an input it enables to filter out pulses shorter than a programmable duration. Each filter consists of a 10-bit down counter, which starts counting at a programmable preloaded value and is decremented using the VCLK2 clock.

- The counter starts counting when the filter input signal has the opposite state of the filter output signal. The output signal is preset to the same input signal state after reset, in order to ensure proper operation after device reset.
- Once the counter reaches zero without detecting an opposite pin state on the filter input signal, the output signal is set to the opposite state.
- When the counter detects an opposite pin action on the filter input signal before reaching zero, the counter is loaded with it's preload value and the opposite pin action on the filter output signal does not take place. The counter resumes at the preload value until it detects an opposite pin action on the input signal again.
- Therefore the filter output signal is delayed compared to the filter input signal. The amount of delay depends on the counter clock frequency (VCLK2) and the programmed preload value.
- The accuracy of the output signal is +/- the counter clock frequency.

Table 23-11 gives examples for a 100 MHz VCLK2 frequency.

Copyright © 2018, Texas Instruments Incorporated

Figure 23-26. Suppression Filter Counter Operation

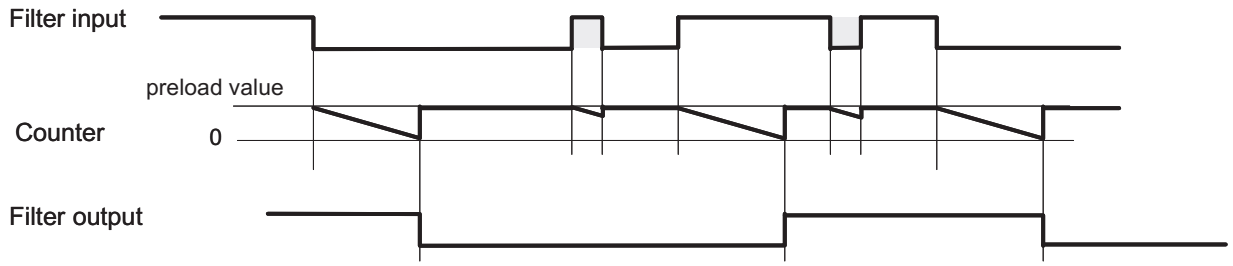


Table 23-11. Pulse Length Examples for Suppression Filter

Divider CCDIV	VCLK2	Possible values for the suppressed pulse length / frequency resulting from the programmable 10 bit preload value (0,1,..,1023)	
1	100.0 MHz	10 ns, 20 ns, …, 10.22 µs, 10.23 µs	50 MHz, 25 MHz, …, 48.924 kHz, 48.876 kHz
2	50.0 MHz	20 ns, 40 ns, …, 20.44 µs, 20.48 µs	25 MHz, 12.5 MHz, …, 24.462 kHz, 24.414 kHz
3	33.3 MHz	30 ns, 60 ns, …, 30.66 µs, 30.69 µs	16.7 MHz, 8.3 MHz, …, 16.308 kHz, 16.292 kHz

23.2.7 Interrupts and Exceptions

N2HET interrupts can be generated by any instruction that has an interrupt enable bit in its instruction format. When the interrupt condition in an instruction is true and the interrupt enable bit of that instruction is set, an interrupt flag is then set in the N2HET Interrupt Flag Register (HETFLG). The address code for this flag is determined by the five LSBs of the current timer program address. The flag in the N2HET Interrupt Flag Register (HETFLG) is set even if the corresponding bit in the N2HET Interrupt Enable Set Register (HETINTENAS) is 0. To generate an interrupt, the corresponding bit in the N2HET Interrupt Enable Set Register (HETINTENAS) must be 1. In the N2HET interrupt service routine, the main CPU must first determine which source inside the N2HET created the interrupt request. This operation is accelerated by the N2HET Offset Index Priority Level 1 Register (HETOFF1) or N2HET Offset Index Priority Level 2 Register (HETOFF2) that automatically provides the number of the highest priority source within each priority level. Reading the offset register will automatically clear the corresponding N2HET interrupt flag that created the request. However, if the offset registers are not used by the N2HET interrupt service routine, the flag should be cleared explicitly by the CPU once the interrupt has been serviced.

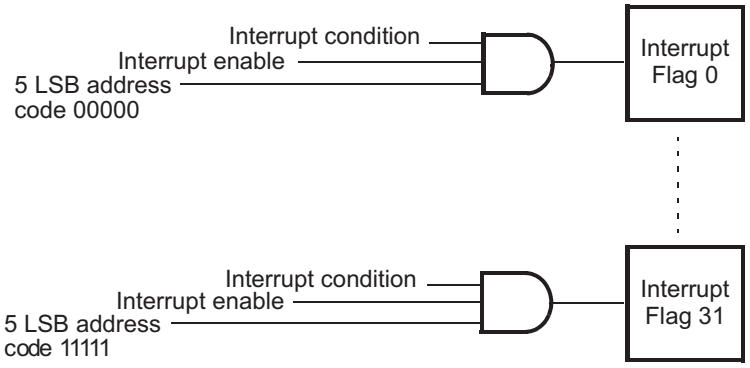

Table 23-12. Interrupt Sources and Corresponding Offset Values in Registers HETOFFx

Source No.	Offset Value
no interrupt	0
Instruction 0, 32, 64...	1
Instruction 1, 33, 65...	2
:	:
Instruction 31, 63, 95...	32
Program Overflow	33
APCNT underflow:	34
APCNT overflow	35

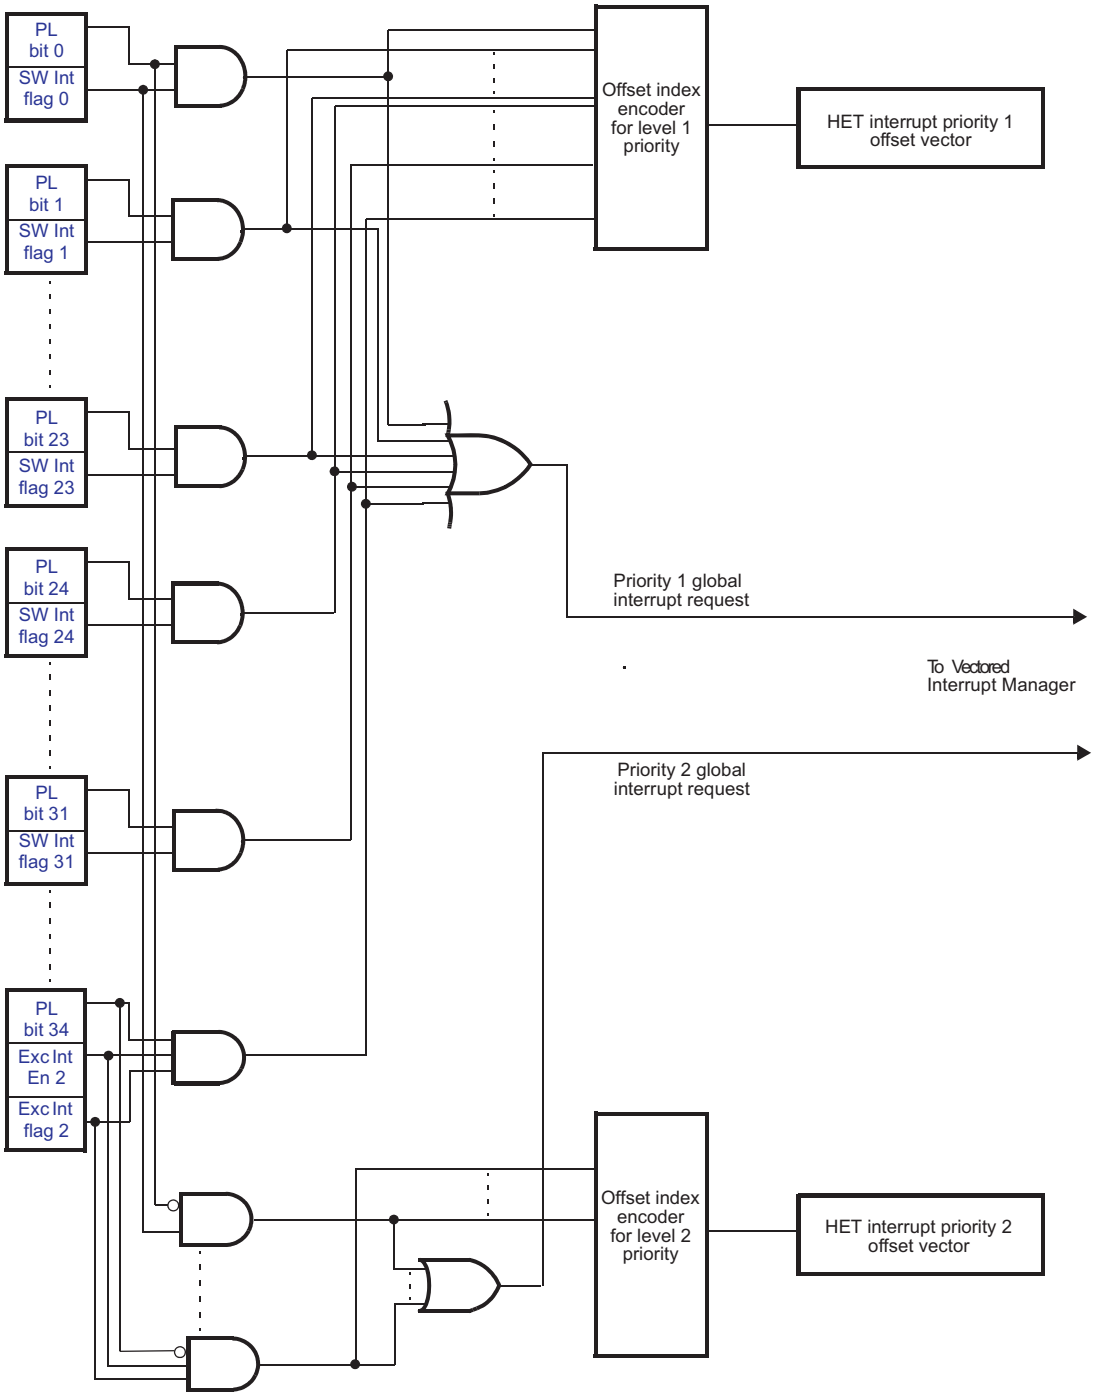
Copyright © 2018, Texas Instruments Incorporated

The instructions capable of generating interrupts are listed in Table 23-75.

Figure 23-27. Interrupt Functionality on Instruction Level

Each interrupt source is associated with a priority level (level 1 or level 2). When multiple interrupts with the same priority level occur during the same loop resolution the lowest flag bit is serviced first.

In addition to the interrupts generated by the instructions the N2HET can generate three additional exceptions:



- Program overflow
- APCNT underflow (see Section 23.3.1.2)
- APCNT overflow (see Section 23.3.1.3)

23.2.8 Hardware Priority Scheme

If two or more software interrupts are pending on the same priority level, the offset value will show the one with the highest priority. The interrupt with the highest priority is the one with the lower offset value. This scheme is hard-wired in the offset encoder. See Figure 23-28.

23.2.9 N2HET Requests to DMA and HTU

As described in Section 23.6.3, the majority of the N2HET instructions are able to generate a transfer request to the High-End Timer Transfer Unit (HTU) and/or to the DMA module when an instruction-specific condition is true. One N2HET instruction can select one of 8 request lines by programming the “reqnum” parameter. The “request” field in an instruction is used to enable, disable, or to generate a quiet request (see Section 23.6.2) on the selected request line. Quiet requests can be used by the HTU, but not by the DMA. For quiet request, refer to the *High-End Timer Transfer Unit (HTU) Module* chapter (see Section 24.2.4.1).

The configuration of the N2HET Request Destination Select Register (HETREQDS) bits determines if a request line triggers an HTU-DCP, a DMA channel or both. This means the register bits will determine whether an N2HET instruction triggers DMAREQ[x], HTUREQ[x] or both signals (shown in Figure 23-29). The request line number x corresponds to the “reqnum” parameter used in the instruction.

Figure 23-29. Request Line Assignment Example

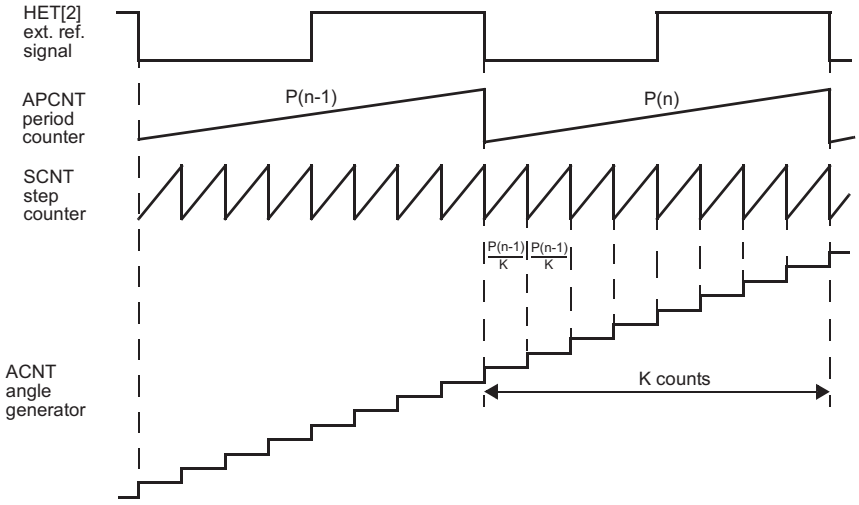
23.3 Angle Functions

Engine management systems require an angle-referenced time base to synchronize signals to the engine toothed wheel. The N2HET has a method to provide such a time base for low-end engine systems. The reference is created by the N2HET using three dedicated instructions with fractional angle steps equal to /8, /16, /32, /64.

23.3.1 Software Angle Generator

The N2HET provides three specialized count instructions to generate an angle referenced time base synchronized to an external reference signal (the toothed wheel signal) that defines angular reference points.

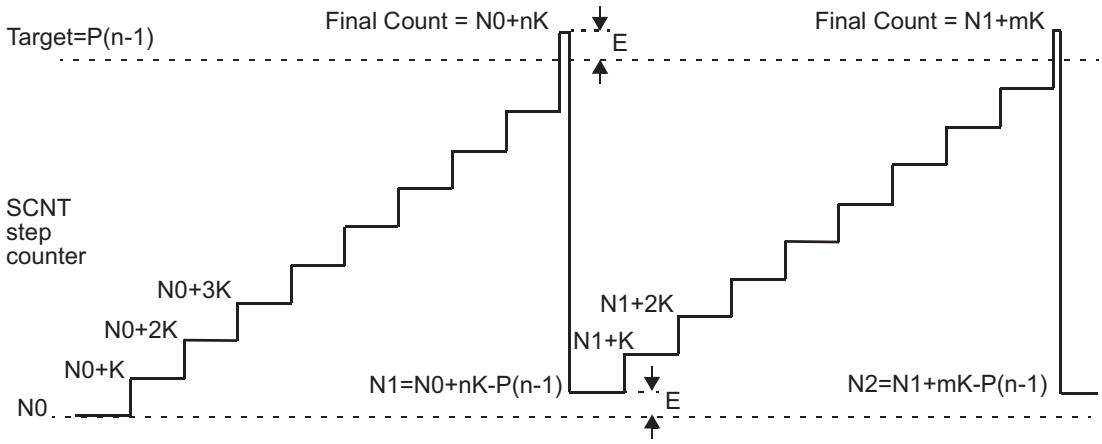
The time base is used to generate fractional angle steps between the reference points. The step width K (= 8, 16, 32, or 64) programmed by the user defines the angle accuracy of the time base. These fractional steps are then accumulated in an angle counter to form the absolute angle value.



The first counter, APCNT, incremented on each loop resolution clock measures the periods P(n) of the external signal. The second counter SCNT counts by step K up to the previous period value P(n-1), measured by APCNT, and then recycles. The resulting period of SCNT is the fraction P(n-1) / K. The third counter ACNT accumulates the fractions generated by SCNT.

Figure 23-30 illustrates the basic operation of APCNT, SCNT, and ACNT.

A N2HET timer program can only have one angle generator.



Copyright © 2018, Texas Instruments Incorporated

Figure 23-30. Operation of N2HET Count Instructions

Due to stepping, the final count of SCNT does not usually exactly match the target value P(n-1). Figure 23-31 illustrates how SCNT compensates for this feature by starting each cycle with the remainder (final count - target) of the previous cycle.

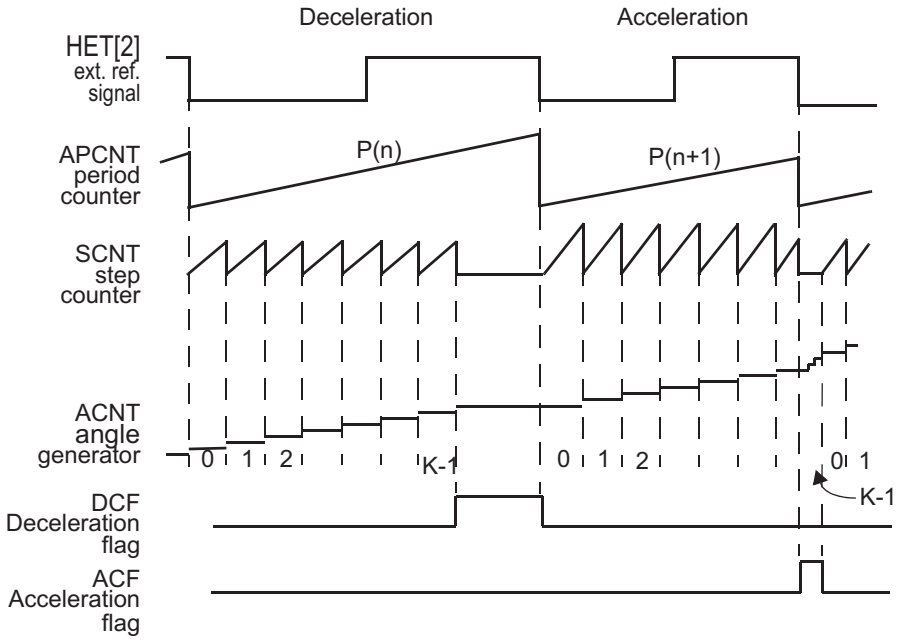


Figure 23-31. SCNT Count Operation

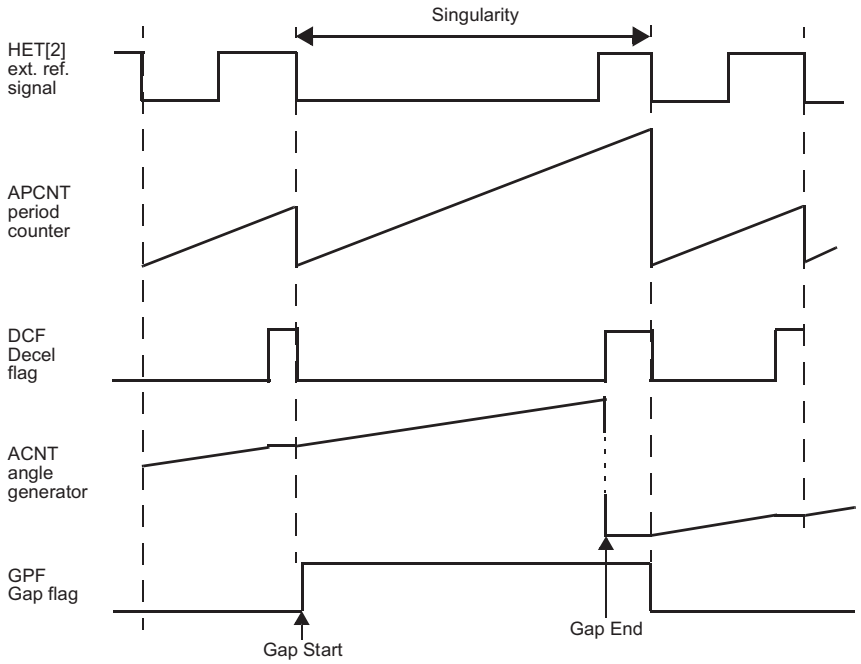
Copyright © 2018, Texas Instruments Incorporated

ACNT detects period variations of the external signal measured by APCNT and compensates related counting errors. A period increase is flagged in the deceleration flag. A period decrease is flagged in the acceleration flag. If no variation is flagged, ACNT increments the counter value each time SCNT reaches its target. If acceleration is detected, ACNT increments the counter value on each timer resolution (fast mode). If deceleration is detected, ACNT is stopped. Figure 23-32 illustrates how the compensations for acceleration and deceleration operate.

Figure 23-32. ACNT Period Variation Compensations

Copyright © 2018, Texas Instruments Incorporated



23.3.1.1 Singularities

Singularities (gaps, in this case, from missing teeth in a toothed wheel) in the external reference signal can be masked. The start and end of singularities are defined by gap start and gap end values specified in SCNT and ACNT. When ACNT reaches gap start or gap end, it sets/resets the gap flag.

While the gap flag is set, new periods of the external reference signal are ignored for angle computation. SCNT uses the last period measured by APCNT just before gap start.

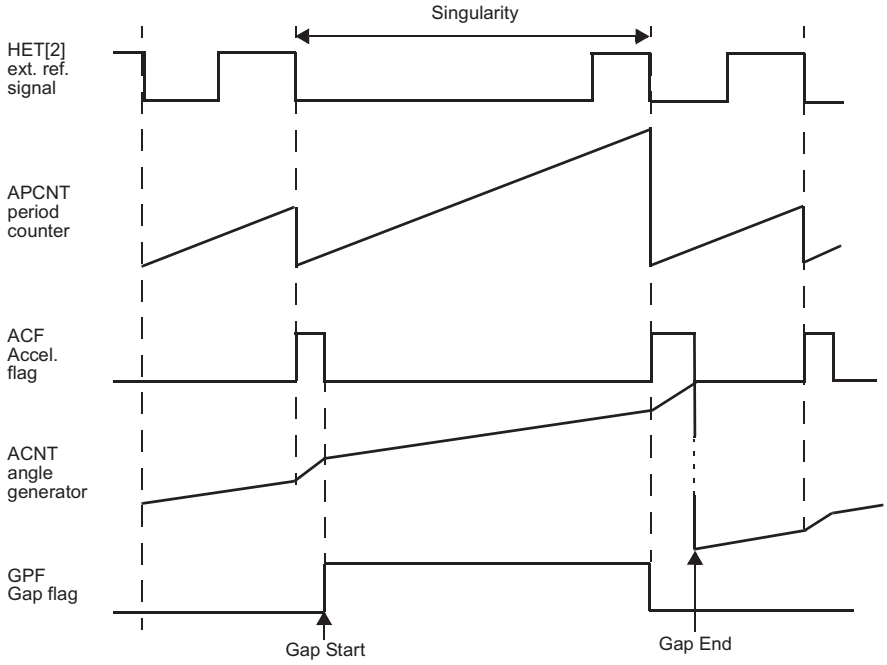


Figure 23-33 and Figure 23-34 illustrate the behavior of the angle generator during a gap after a deceleration or acceleration of the N2HET.

Figure 23-33. N2HET Timings Associated with the Gap Flag (ACNT Deceleration)

Copyright © 2018, Texas Instruments Incorporated

Figure 23-34. N2HET Timings Associated with the Gap Flag (ACNT Acceleration)

23.3.1.2 APCNT Underflow

The fastest valid external signal APCNT can accept must satisfy the following condition:

Step Width K < Period Min. Resolution (LRP)

This condition fixes the maximum possible step width once the minimum period and the resolution of an application are specified.

If a period value accidentally falls below the minimum allowed, APCNT stops the capture of these periods and sets the APCNT underflow interrupt flag located in the exceptions interrupt control register. In such a situation, SCNT and ACNT continue to be executed using the last valid period captured by APCNT.

23.3.1.3 APCNT Overflow

The slowest valid external signal APCNT can measure must satisfy the following condition:

Period Max Resolution < 33554431

When this limit is reached (APCNT Count equals all 1's), APCNT stays at a maximum count (stops counting). APCNT remains in this position until the next specified capture edge is detected on the selected pin and sets the APCNT overflow interrupt flag located in the exceptions interrupt control register. In this situation, SCNT and ACNT continue to be executed using the maximum APCNT period count.

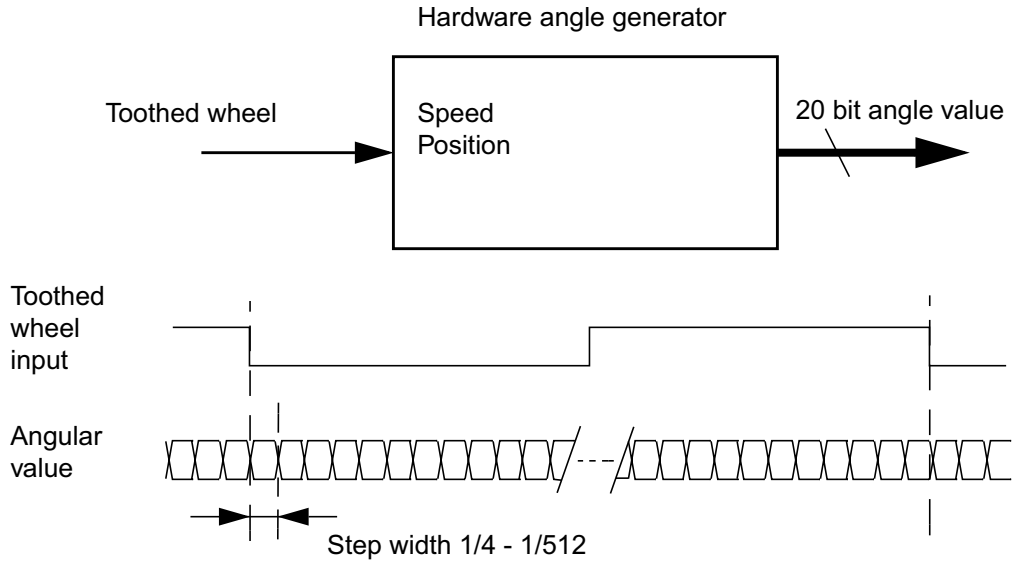
23.3.2 Hardware Angle Generator (HWAG)

23.3.2.1 Overview



More engine control functions require powerful microcontrollers to process the timing. These controllers must generate signals such as dwell time, spark time, and fuel injection, at precise engine angles. These signals must be synchronized with the engine cycle.

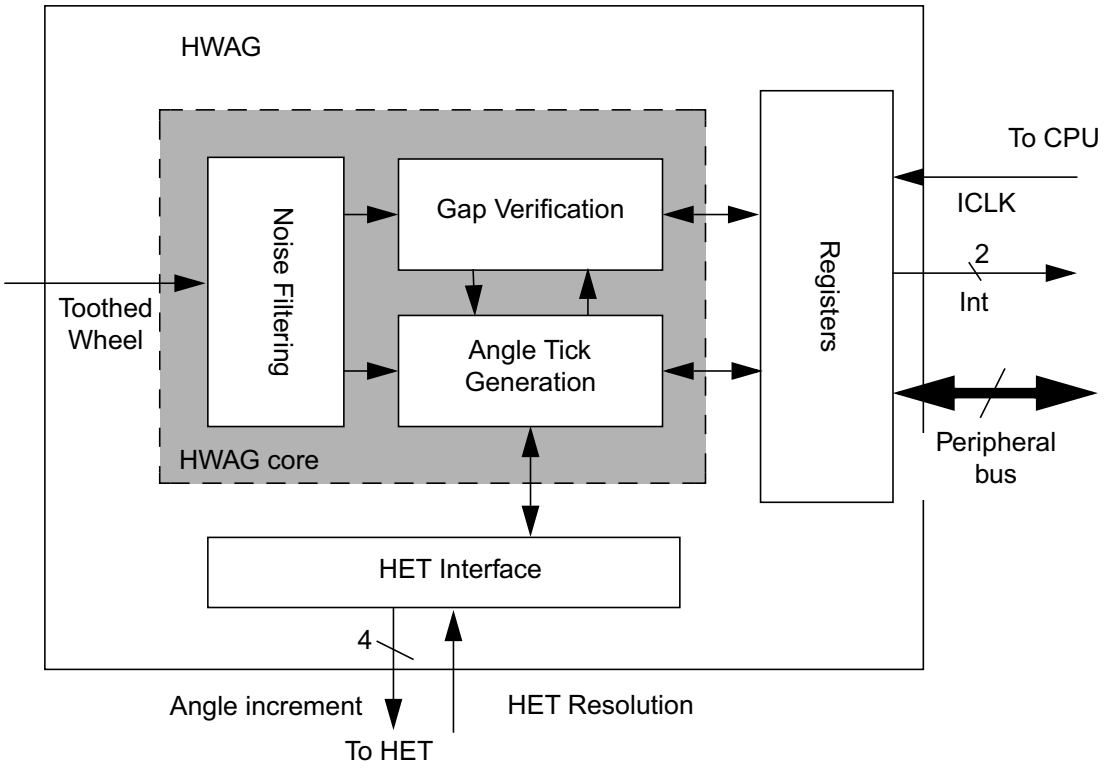
The hardware angle generator (HWAG) generates angle value from toothed wheels. Because the toothed wheels are inaccurate (the most widely wheel used has 60 teeth with 6°/tooth), the period between two tooth edges (\) interpolates the angle value and the step width gives the number of interpolated angles. For an example of the angle generator principle, see Figure 23-35.

The HWAG can complement the high-end timer (NHET) to generate complex angle-angle or angle-time wave forms.

To work with the majority of toothed wheels, the HWAG provides registers to allow the CPU to configure step width, singularity, and filtering when initializing.

Figure 23-35. Angle Generator Principle

23.3.2.1.1 HWAG Features



The HWAG provides the following features:

- Programmable step width from 1/4 to 1/512
- Automatic synchronization check after first singularity synchronization
- Direct interface with the high-end timer
- 15 to 10,000 RPM range
- Programmable toothed-wheel input filter
- Programmable active edge on toothed-wheel
- Start bit synchronized to the tooth edge
- Pin selection capability for toothed-wheel input

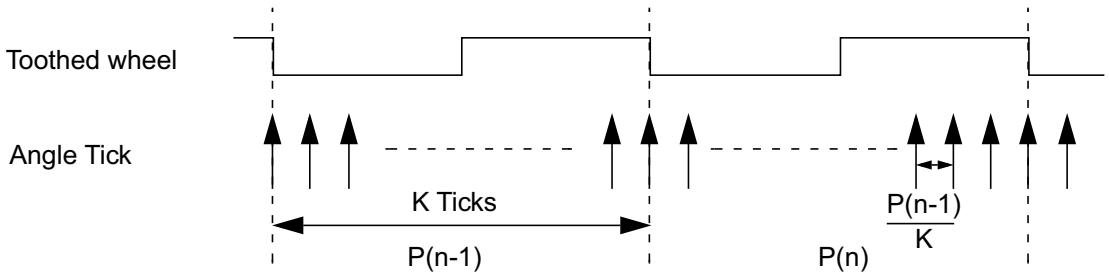
23.3.2.2 HWAG Operation

23.3.2.2.1 Angle Tick Generation Algorithm

23.3.2.2.1.1 Angle Tick Generation Principle

The angle tick generator is the core kernel of this module. It uses the time-interpolation algorithm to generate angle ticks based on the last toothed wheel period. The angle counter is incremented at each new angle tick.



Because the toothed wheel is too inaccurate to fit with actual power-train applications, the algorithm is based on dividing the previous tooth period by K angle steps. The tooth period is the period between two active edges, which the HWAG global control register 2 (HWAGCR2) defines as the falling or the rising edge of the input signal. For an example of the angle tick generation principle, see Figure 23-37.

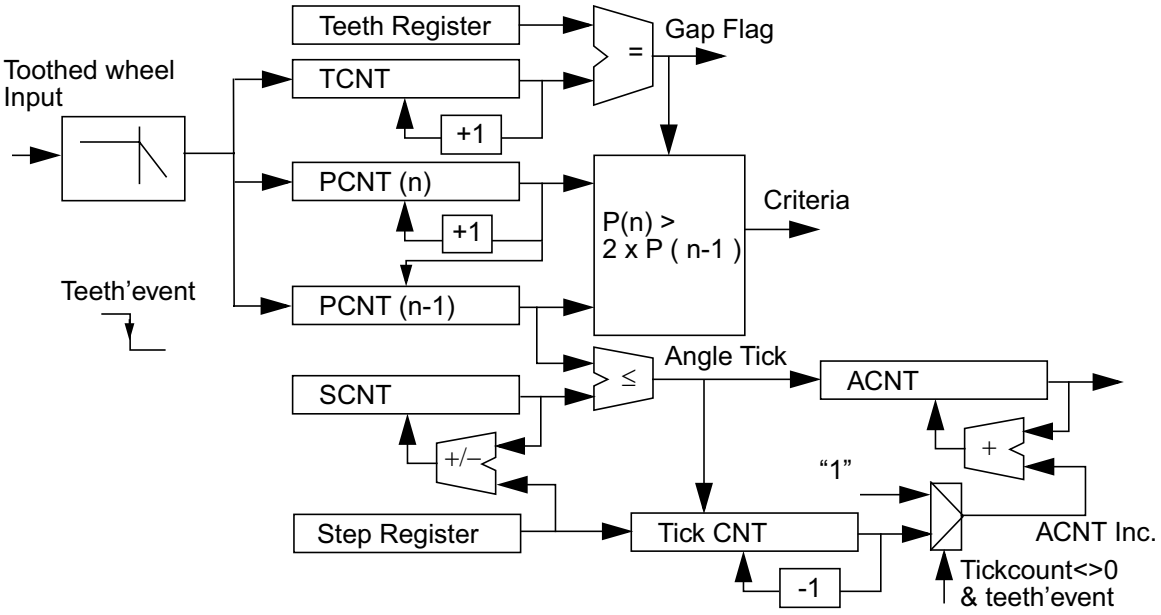
The speed of the toothed wheel varies. This variance in speed creates some discontinuities in the angle counter behavior.

When the toothed wheel accelerates, the current period becomes shorter than the previous one and the tooth edge arrives before the last tick has been generated. To compensate for any missed ticks, the HWAG adds them to the angle counter when the active edge of the tooth arrives. The angle value is updated and resynchronized at each new active tooth edge.

When the toothed wheel decelerates, the period becomes longer than the previous period and K ticks are already counted before the active edge tooth arrives. After the last tick has been generated, the HWAG generates a tick only after the active tooth edge arrives.

Figure 23-37. Angle Tick Generation Principle

Copyright © 2018, Texas Instruments Incorporated



23.3.2.2.1.2 Angle Tick Generation Implementation

The time-interpolation algorithm, which generates ticks based on the toothed wheel tooth period, consists of the following five main counters linked together:

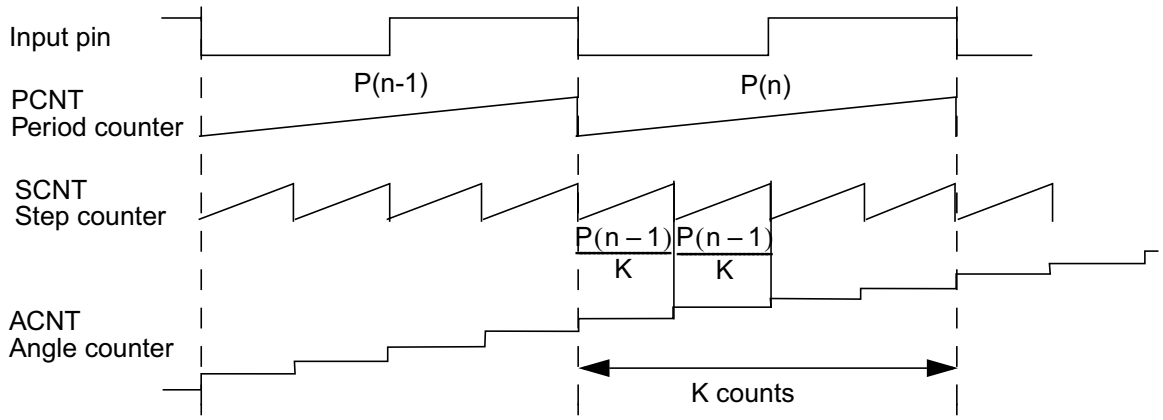
- Tooth counter (TCNT): Current tooth
- Period counter (PCNT): Period between two teeth
- Step counter (SCNT): Angle step
- Tick counter (TCKC): Angle ticks
- Angle counter (ACNT): Angle value

The algorithm also includes differences comparison, adder, and working registers as shown in Figure 23-38.

Figure 23-38. New Angle Tick Generation Architecture

The TCNT is an 8-bit counter. It counts teeth until it reaches the teeth register value then generates a gap flag signal. The gap flag signal which changes the behavior of the HWAG during the singularity and resets the TCNT on the next active edge of the toothed wheel input.

The PCNT calculates the period P(n) between two teeth (two active edges on the toothed wheel input). The active edge (falling or rising) is selected by setting the TED bit in the HWAG global control register 2 (HWAGCR2). On an active edge from the toothed wheel input, the PCNT is saved in the HWAG previous tooth period value register (HWAPCNT1).



The SCNT counts by K steps up to the previous period value, which is contained in the HWAPCNT1 register. When the SCNT overflows PCNT(n-1), an angle tick is generated and SCNT is reset to the remainder between the SCNT and PCNT(n-1). The resulting period of the SCNT is the fraction PCNT(n-1)/K.

The TCKC counts every angle tick until it reaches K and then stops the SCNT. If an active edge occurs before the TCKC has reached K, the remainder is added directly to the ACNT.

When encountering an earlier active edge, the ACNT accumulates the fractions (angle ticks) generated by the SCNT and the remainder of the TCKC. For an example of angle generation using the time-based algorithm, see Figure 23-39.

Copyright © 2018, Texas Instruments Incorporated

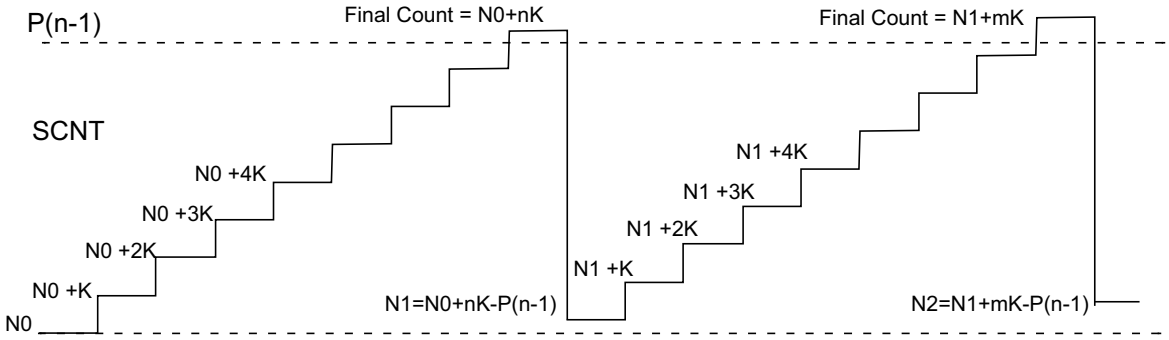


Figure 23-39. Angle Generation Using Time Based Algorithm

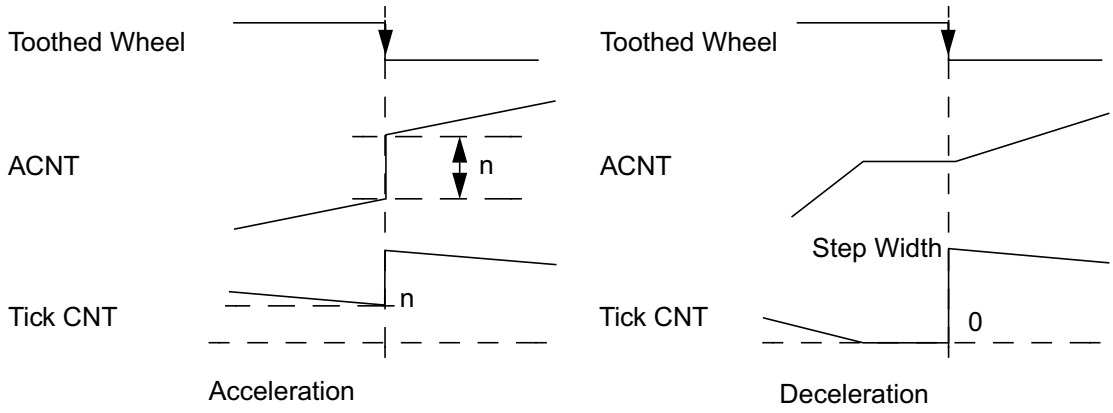
Because of stepping, the final count of the SCNT will usually be unequal to the target value PCNT(n-1) and then will overflow. To compensate for this error generated by the algorithm, reset the SCNT to the remainder of the difference between (SCNT - PCNT(n-1)).

To see how the SCNT and PCNT(n-1) generate angle ticks and compensate for the error due to the integer fractions, see Figure 23-40.

Figure 23-40. SCNT Stepping Compensation

Copyright © 2018, Texas Instruments Incorporated



23.3.2.2.1.3 Acceleration and Deceleration

Because the toothed wheel speed is inconstant, it creates discontinuities in the angle counter behavior.

If the TCKC reaches zero before a new active tooth edge during a deceleration, the angle tick signal is no longer generated by the SCNT and PCNT(n-1). This halts the ACNT until the new active tooth arrives.

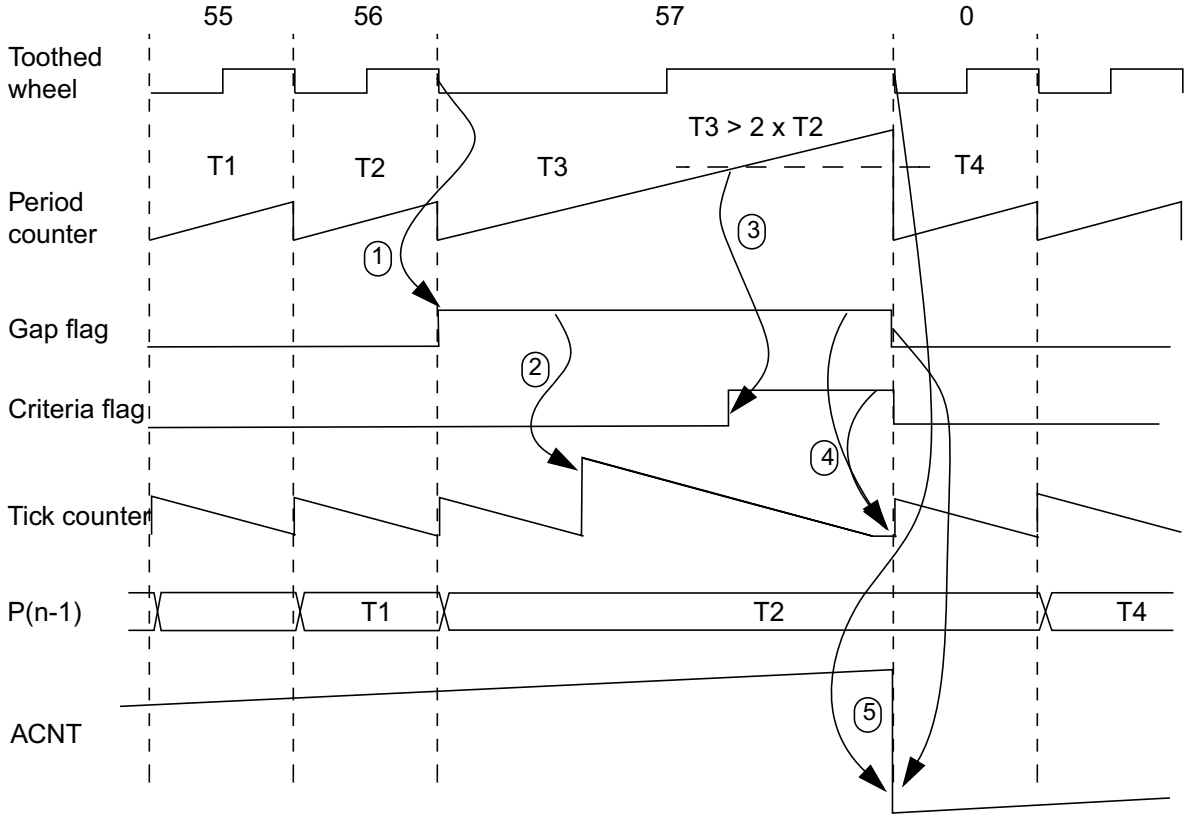
If the TCKC is unequal to zero when the new active tooth edge arrives during an acceleration (that is, the falling edge on the toothed wheel input in the example below), the rest of the tick counter increments the ACNT. For an example of the ACNT during acceleration and deceleration, see Figure 23-41.

Figure 23-41. ACNT During Acceleration and Deceleration

23.3.2.2.1.4 End of Cycle

The HWAG behaves differently during the singularity tooth period of the toothed wheel. During the singularity period, the HWAG counts three virtual teeth (that is, three times the step width is added to the ACNT) to ensure that the ACNT reaches the maximum value (that is, every angle step has been counted) before resetting it.

During the singularity period, the HWAG generates angle ticks like for a normal tooth but with three times the value. To generate these angle ticks, the HWAG uses a constant period based on the previous tooth period. Because the period is based on the previous tooth period, the HWAG must recover from a deceleration or acceleration of three teeth when realizing the active edge tooth at the end of the singularity tooth.



The HWAG must ensure that the singularity occurs where expected and must verify it. When the singularity tooth arrives, TCNT reaches the teeth register, sets the signal gap flag, and then keeps PCNT(n-1) until the first tooth of the next round has passed. Because of these conditions, angle ticks before the second tooth will be based on the previous singularity tooth period.

The tick counter is first loaded with a normal value. When the counter reaches zero, it is reloaded once with twice the step width value if the criteria flag is not set. PCNT(n) continues to be incremented and to check the criteria with PCNT(n-1). For more information on gap verification, see Section 23.3.2.2.4. The SCNT continues to generate angle ticks until the tick counter reaches zero the second time. The criteria flag validates the tooth in order to reset the counters. For an example of how the criteria flag validates the tooth to reset the counters, see Figure 23-42.

When the tooth active edge occurs, the ACNT is incremented with the remainder value if the tick counter is not equal to zero. When the ACNT contains a value equals to K times the teeth register, the PCNT, the TCNT and the ACNT are reset to begin a new revolution.

Copyright © 2018, Texas Instruments Incorporated

Figure 23-42. Singularity Check, ACNT Reset and Timing Associated

1. When TCNT = teeth register, the Gap flag is raised
2. Tick CNT reloads automatically with 2x the step-width because the Gap flag = '1'
3. If PCNT (n) > 2 x PCNT (n-1) and the Gap flag = '1' then the Criteria flag is raised
4. The tick counter is not reloaded because the Criteria flag is raised
5. The Gap flag and tooth active edge reset, followed by ACNT

23.3.2.2.2 Angle Zero Initialization

Before any angle operation, initialize the HWAG and then initialize the angle zero as the singularity tooth. To initialize the angle zero as the singularity tooth, the HWAG can send an interrupt at each new tooth to help the software detect the first tooth if the interrupt is set. This allows you to decide which algorithm to apply to detect the zero degree tooth (by enabling the corresponding interrupt, you can also use the wired criteria).

When researching which algorithm to apply, the counters ACNT and TCNT are frozen and must be initialized to their start values. The ACNT value is equal to T times the step value (T is the tooth where the start will take effect and the initial value of the tooth counter). The counters PCNT(n) and PCNT(n-1) contain the current period and the previous period respectively. These counters allow you to set a detection criteria. When the application software sets the start bit, the software unfreezes the ACNT and TCNT counters. The counters count from the preloaded values at the next tooth active edge. The ACNT is preloaded with the value of 2 teeth and started synchronously with the next active edge of the toothed wheel. For an example of the HWAG start sequence, see Figure 23-43.

Figure 23-43. Example of HWAG Start Sequence

Copyright © 2018, Texas Instruments Incorporated

Figure 23-44 is an example of a singularity research initializing the HWAG at the second tooth to start synchronously with the third tooth. The HWAG angle value register (HWAACNT) contains 1024 (2 × 512) and the HWAG current teeth number register (HWATHVL) contains 2.

The code is executed in a tooth interrupt subroutine in code using the PCNT(n-2) > PCNT (n-3) + PCNT (n-1) algorithm.

Figure 23-44. Code

```

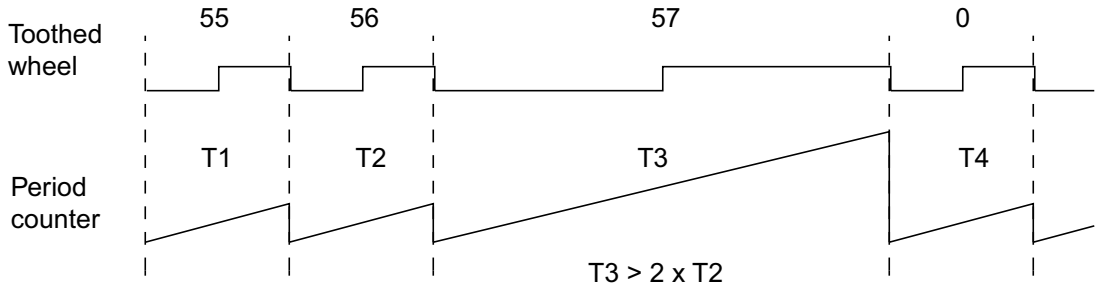
PCNT3     DCD       0x00000000 ; reserved memory for PCNT (n-3)
```

23.3.2.2.3 Stopping the HWAG

The HWAG starts synchronously with the active edge of the toothed wheel, but stops when the start (STRT) bit in the HWAG global control register 2 (HWAGCR2) is reset. Within a tooth, the HWAG can be stopped and parameters can be changed (that is, step width, angle counter, and so on) If this happens, the restart will take effect on the next active tooth edge.



NOTE: When stopping the HWAG, stop the angle increment delivered to the NHET and set it to zero. Reload the NHET counter with the same value of the angle counter (± corrections), if restarting the HWAG.

23.3.2.2.4 Gap Verification

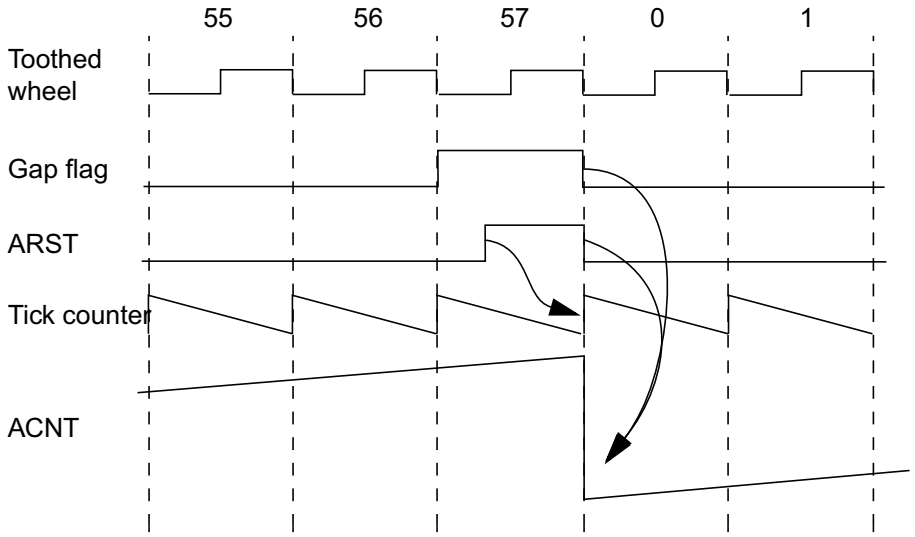
After the CPU sets the synchronization and puts the HWAG into RUN time (that is, the start bit is set), the tooth counter counts until reaching the teeth register (the number of real teeth of a full wheel revolution). When the tooth counter reaches the teeth register, the gap flag signal is set. For more information on the end of the cycle, see Section 23.3.2.2.1.4. When the gap flag signal is set, it allows the HWAG to verify if the singularity is in the correct position (last tooth). The module then applies the PCNT(n) > 2 x PCNT(n-1) criteria by comparing PCNT(n) and PCNT(n-1) with one bit left shifted. If the criteria does not match when the tooth arrives, then the HWAG sends an interrupt to the CPU and does not reset the ACNT counter. The application software must recover from such an interrupt to keep the HWAG operating optimally. For an example of gap verification criteria for a 60-2 toothed wheel, see Figure 23-45.

Figure 23-45. Gap Verification Criteria For a 60-2 Toothed Wheel

If the hardware criteria is not enabled, you must set the angle reset (ARST) bit in the HWAG global control register 2 (HWAGCR2) to validate the singularity. The HWAGCR2 register must validate the singularity before the active edge of the singularity tooth. If the HWAGCR2 register fails to validate the singularity, the HWAG generates an interrupt and does not clear the ACNT counter when the tooth edge occurs.

NOTE: For a 60-2 toothed wheel, set the ARST flag after the reload of the tick counter(when PCNT(n) = PCNT(n-1)). By verifying the criteria, the application software can set the ARST bit after this point.

The CPU can read the PCNT counter and make a custom criteria set the ARST bit on time for the HWAG. The application software can use the gap flag interrupt to find the singularity tooth. Alternately, the CPU can verify the validity of the singularity in the second tooth with a more accurate criteria by using the HWAG previous tooth period value register (HWAPCNT1).



Copyright © 2018, Texas Instruments Incorporated

23.3.2.2.4.1 Use of the ARST Bit In Case of a Toothed Wheel Without Singularity

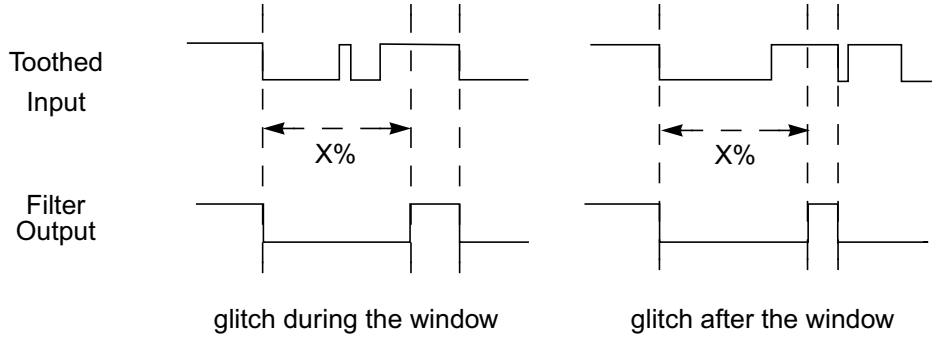
If a toothed wheel has no singularity (that is, no missing teeth), the ACNT must be reset when it reaches the angle zero point. To reset the ACNT when it reaches the angle zero point, set the ARST bit to 1.

Setting the ARST bit before the reload of the tick counter will cause the HWAG to fail to reload the tick counter. The HWAG will act like a normal tooth but the next active edge on the toothed wheel input will reset the ACNT and TCNT and clear the ARST bit. For an example of using the ARST bit in a toothed wheel without singularity, see Figure 23-46.

Figure 23-46. Using the ARST Bit in a Toothed Wheel Without Singularity

Copyright © 2018, Texas Instruments Incorporated

23.3.2.2.5 Input Noise Filtering



The toothed wheel input comes from an analog part and is sensitive to external noise. Due to this sensitivity, the input needs to be filtered because of glitches in the signal.

The HWAG digitally filters the toothed wheel input signal before it is used inside the core. The filter blocks the signal which negates the effect inside the HWAG. The HWAG provides two filter registers that filter the same way.

The filters validate the input signal after n angle ticks. The n angle ticks are like X% of the tick counter. The value of the remaining percentage of the tick counter (1- X%) need to be set because the tick counter is a down counter. Calculate the value to put into the filter registers from the step width value (or angle ticks value per tooth). The toothed wheel input is like a low pass filter with a cut-off frequency that functions like a toothed-wheel speed, but without acceleration and decelerations side effects. For an example of a windowing filter for a toothed wheel input on a falling active edge, see Figure 23-47.

NOTE: At any time, the CPU can modify the filter values to fine tune with the application.

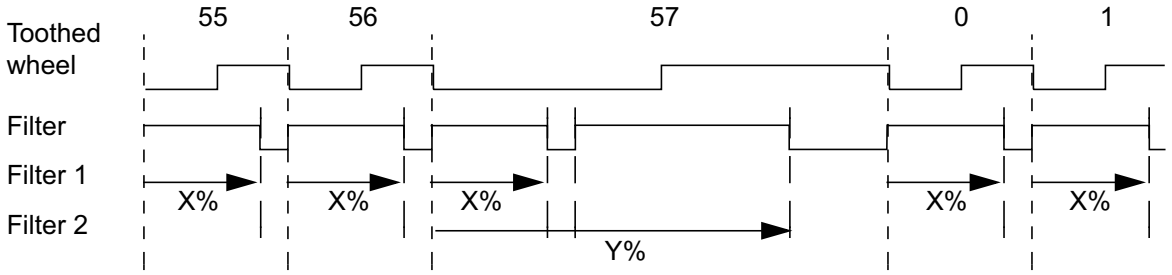
Figure 23-47. Windowing Filter for Toothed Wheel Input on Falling Active Edge

To calculate this number:

Step Width × (1 – X%) = Filter Register Value

If the step width value is equal to 512 and you want to filter 75% of the tooth, calculate the filter register as follows:

512 × (1 – 0.75) = 128



When the tick counter reaches the filter register value, the toothed wheel input is unblocked.

Copyright © 2018, Texas Instruments Incorporated

23.3.2.2.5.1 Filter During Singularity Tooth

During the singularity tooth, the filter acts differently than during a normal tooth. The filter releases the input for a normal tooth. When the tick counter is reloaded, a second filter value is applied to the toothed wheel input. For an example of filtering during a singularity tooth, see Figure 23-48.

Figure 23-48. Filtering During Singularity Tooth

The second filter value is set using the same equation as the first filter with the step width multiplied by 3.

To calculate this number:

(3 × Step Width) × (1 – Y%) = Second Filter Register Value (30)

If the step width value is equal to 512 and you want 70% of singularity tooth period to be filtered, calculate the filter register value as follows:

3 × 512 × (1 – 0.70) = 460

23.3.2.2.6 HWAG Interrupts

When conditions are set, the HWAG interrupts are generated.

When the interrupt condition is true, the corresponding flag is set in the HWAG interrupt flag register (HWAFLG). If the corresponding enable bit in the HWAG interrupt enable set register (HWAENASET) is also set, an interrupt request is sent to the CPU through one of the interrupt lines, depending on the priority of the interrupt (HWAG interrupt level set register (HWALVLSET)).

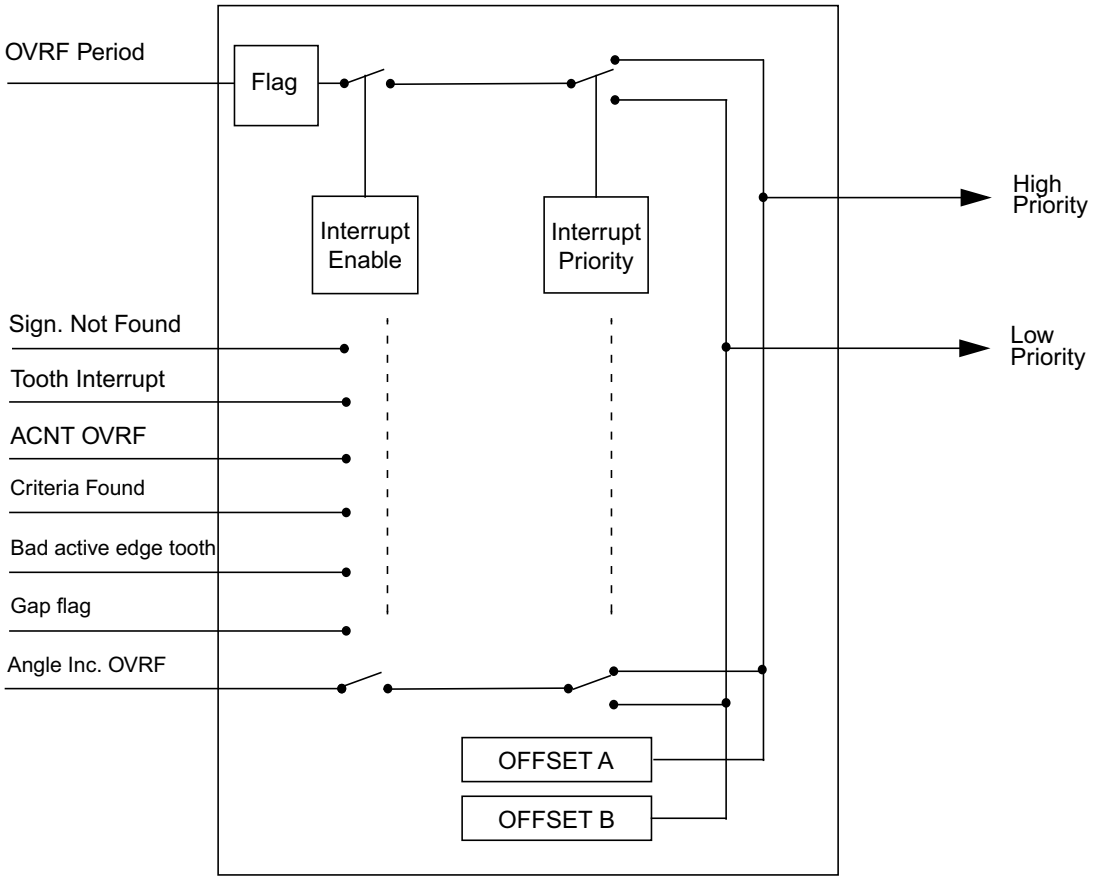
Because the HWAG can set interruptions, the CPU must determine which source created the interrupt request and then execute the interrupt service routine. The CPU reads the offset register (HWAOFFx) that gives the number of the source. If the CPU reads the offset register, it will automatically clear the source flag that created the request.

NOTE: If the corresponding enable bit is not set, a read in the offset register will not clear a flag. To set the bit, write a 1 in the corresponding bit within the HWAG interrupt flag register (HWAFLG).

The HWAG generates eight different interrupts:

- 0 = Overflow period
- 1 = Singularity not found
- 2 = Tooth interrupt
- 3 = ACNT overflow
- 4 = PCNT(n) > 2 × PCNT (n-1) during normal tooth
- 5 = Bad active edge tooth
- 6 = Gap flag
- 7 = Angle increment overflow

Copyright © 2018, Texas Instruments Incorporated



For more information on these interrupts, see Table 23-14. Each interrupt source is associated with a low or high priority. When one or more interrupts with the same priority occur, a fixed priority determines the offset vector if the corresponding enable bits are set.

The HWAG generates two interrupt request signals for the central interrupt module (CIM). For information on servicing interrupts, see Figure 23-49. For a list offset values, see Table 23-13.

Table 23-13. HWAG Interrupt Sources and Offset Values

Source Number	Offset Value
0	1
1	2
:	:
7	8

Table 23-14. HWAG Interrupt Descriptions

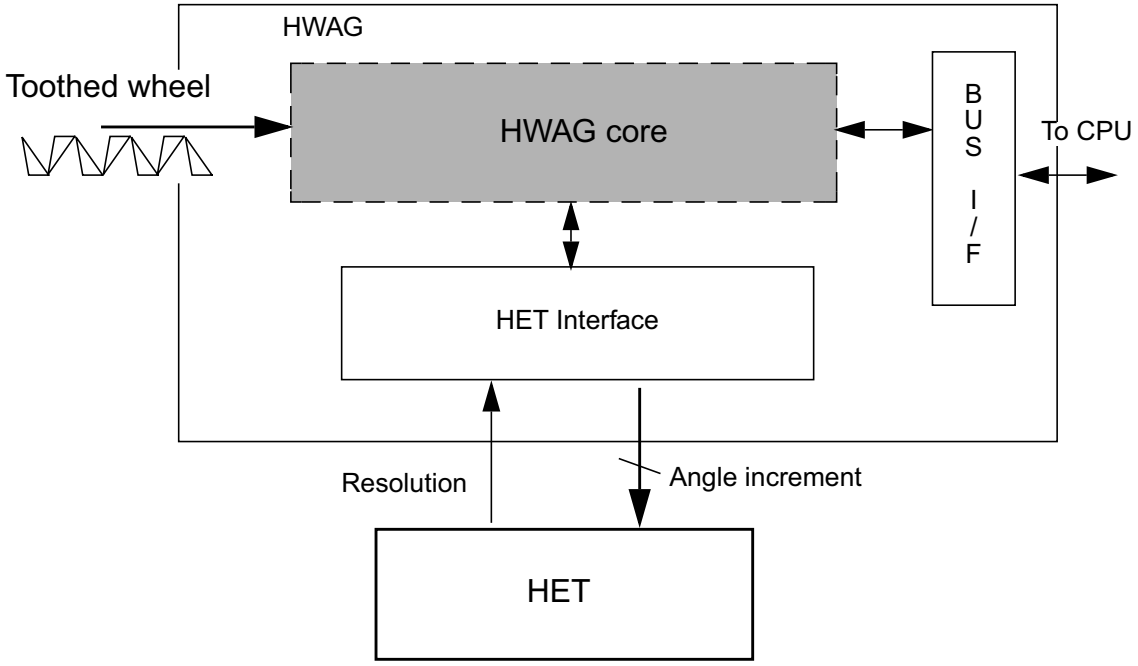
Interrupt Names	Interrupt Descriptions
Overflow period	Occurs when the PCNT (n) counter reaches the maximum value. Can occur if the toothed wheel input remains stable. May indicate failure of an engine stall or a toothed wheel sensor.
Singularity not found	When the TCNT counter sets the gap flag, the HWAG waits for the criteria flag to raise before the toothed wheel active edge. If the toothed wheel active edge occurs before the criteria flag, the HWAG raises the singularity not found interrupt flag.
New edge tooth	This interrupt can sync or let you control the tick generation. This interrupt indicates the new active edge tooth. This interrupt could be filtered or unfiltered (Bit FIL in control register).
Angle counter (ACNT) overflow	This interrupt occurs when the singularity is unable to be found. The angle counter (ACNT) continues until overflow.
Singularity found during normal tooth	This interrupt indicates that the period of the current tooth is at least two times longer than the previous one when the HWAG expects a normal tooth. This interrupt can detect the singularity without bit manipulation by the CPU.
Bad active edge tooth	This interrupt indicates that an active edge has occurred before the end of the filtering (toothed wheel input blocked) but the HWAG remains inactive internally. This interrupt can detect glitches on the toothed wheel input.
Gap flag	When TCNT reaches the teeth register and the HWAG raises the gap flag , This interrupt is set when the gap flag is raised by the HWAG,
Angle increment overflow	This interrupt indicates that the number of the angle increment is more than 15 since the last resolution tick. This interrupt can prevent any discrepancies between the NHET and the HWAG.

NOTE: Before enabling any interruption, clear the HWAG interrupt flag register (HWAFLG) to ensure that any interrupts have finished. If interrupts are pending, the HWAG could generate an interrupt based on an unrealistic event.

23.3.2.3 Emulation

Because the HWAG is designed to synchronize with a real-time environment, the HWAG counters continue during emulation.

When the CPU is frozen, the HWAG continues to run and update registers. Only the offset registers remain uncleared when entering debug mode.



During debug mode, interrupts can occur and will wait until the CPU enters run mode again. If interrupts occur, they could affect synchronization with the toothed wheel

23.3.2.4 Hardware Angle Generator and High-End Timer

In the engine management application, the HWAG is usually connected to one or more high-end timers. This connection allows you to perform angle compare and angle/time compare. For an example of the hardware angle generator/high-end timer interface, see Figure 23-50.

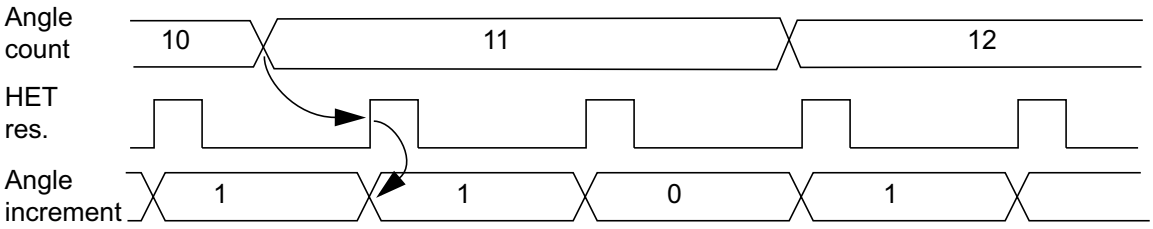

Figure 23-50. Hardware Angle Generator/High End Timer Interface

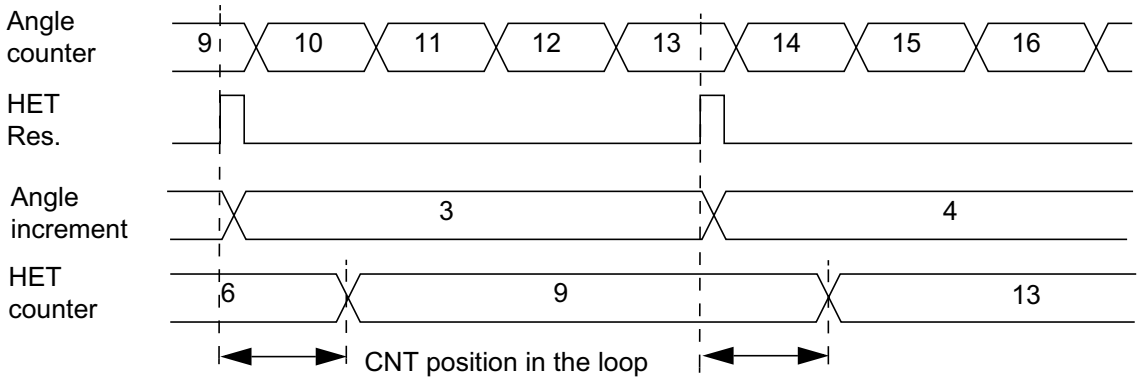
23.3.2.4.1 Signal Description

To perform a resynchronization, the HWAG interface provides to the NHET at every resolution clock an angle increment value that represents how much the angle counter of the HWAG has been incremented since the last NHET resolution clock. For an example of the angle count within the HWAG, see Figure 23-51.

Figure 23-51. Angle Count Within the HWAG at Resolution Clock

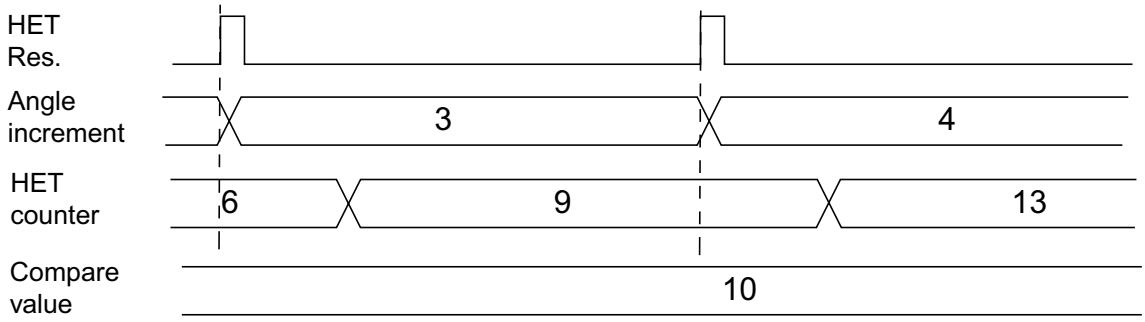


Copyright © 2018, Texas Instruments Incorporated

When the engine speed increases, the angle count can increment by more than one in a NHET resolution but the HWAG will continue to provide the angle increment value at every resolution..

The NHET can then implement its own angle counter (using a CNT instruction in angle mode) which will be incremented once per resolution by the value given by the angle increment. For an example of an angle count within the NHET with increments, see Figure 23-52.

Figure 23-52. Angle Count Within the NHET With Increments

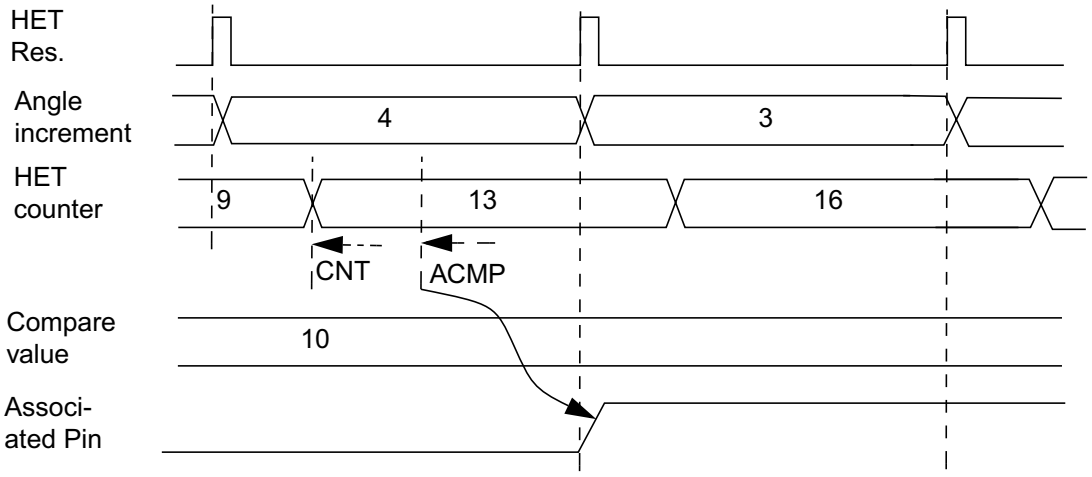


23.3.2.4.2 NHET Operation on Angle Functions (ACMP, CNT)

23.3.2.4.2.1 State of the Art

Because the angle value can be increased by more than one, the compare value could be in-between the old angle value and the new angle value of the NHET angle counter (where new angle value = old angle value + angle increment). To perform an angle compare that ensures not to miss a compare value, the NHET provides the ACMP instruction. For an example of a compare without ACMP instruction, see Figure 23-53.

Figure 23-53. Compare Without ACMP Instruction



When the HET counter passes from 9 to 13, the equality compare can not match the compare value 10. Consequently, the angle position is missed!

Copyright © 2018, Texas Instruments Incorporated

23.3.2.4.2.2 ACMP Instruction Advantage

The ACMP instruction is more than an equality compare. ACMP instruction performs an in-between comparison (old angle value < compare value ≤ new angle value) to match the position of the toothed wheel. This instruction, where an equality compare executes every resolution, may miss a compare match. For an example of ACMP compare within the NHET, see Figure 23-54.

Figure 23-54. Example of ACMP Compare Within the NHET

With the ACMP instruction, the compare that is performed will be: **9** < **10** ≤ **13**

With the ACMP instruction, the compare is: 9 < 10 ≤ 13

NOTE: To avoid multiple matches, the ACMP only matches during a single resolution.

Performing the following equations at the same time implements this compare:

CMP > NHET angle counter – Angle increment

CMP ≤ NHET angle counter

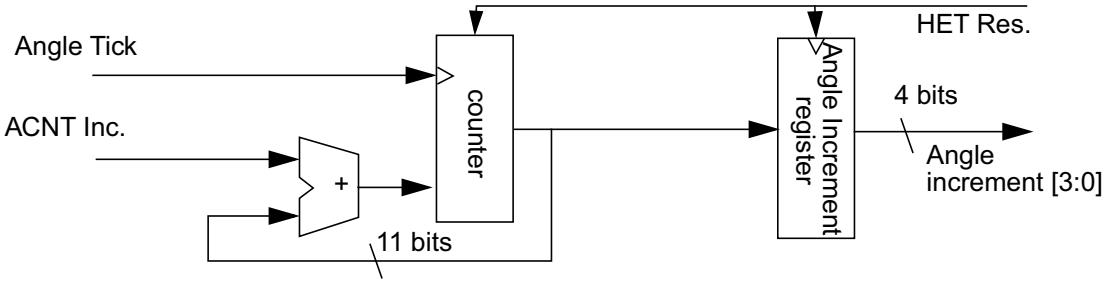
23.3.2.4.3 NHET Interface

23.3.2.4.3.1 Input Signal Selection

The input pin of the toothed-wheel signal is software selectable. In previous generations of NHET/HWAG, this was fixed to HET[2]. On this device, the input pin is programmable to provide more flexibility for the system implementation. However, the implementation is done in a way to be backward compatible.



A separate register, HWAG pin select register (HWAPINSEL), is implemented to allow this selection functionality. The HWAPINSEL register should be programmed before the HWAG is turned on. The default selection will be HET[2] (PINSEL = 2h) after reset. The signals will be derived from the input buffer of each pin. This will allow configuring the pin as an output and measure back the output signal with the HWAG.

You can change the HWAPINSEL register at any time, but the proper functionality of the HWAG is not assured if the selection is changed while the HWAG is already operational. It is recommended that the input selection is done before the STRT bit in the HWAG global control register 2 (HWAGCR2)) is programmed to 1.

23.3.2.4.3.2 HWAG to NHET Interface

The NHET interface is a 11-bit counter sampled by the NHET and reset by the NHET resolution. The counter contains the value of ACNT incremented during the last resolution (see Section 23.3.2.4.1). For the NHET interface block diagram, see Figure 23-55.

Figure 23-55. NHET Interface Block Diagram

When the ACNT register is reset to zero, the angle increment register is not reset. The NHET software checks if its own angle register is higher than 360° and either clears it or continues to 720°. If ACNT is reset within the HWAG, the angle increment register gives the NHET the number of angle ticks from the last resolution.

During a strong acceleration after a tooth active edge, the number of angle ticks can exceed 15. If the number of ticks exceeds 15, the HWAG delivers to the NHET several angle increments at 15. This allow the NHET to follow without missing any angle positions from the HWAG. When the counter is below 15, the angle increment reflects the counter. When the angle increment overflows, sets to 15, and if the enable bit (bit 7 in the control register) is set, the HWAG can send an interrupt to the CPU.

During a strong deceleration, the angle increment can stay null for one or more NHET resolution clocks.

To minimize the error between the fly-wheel and NHET angle counter, the step width and the NHET resolution must be set to avoid any overflow of the 11-bit counter of the NHET interface. This can happen if the number of angle ticks always exceeds 15 during one resolution.

23.3.2.5 Range of Operations

23.3.2.5.1 Intrinsic HWAG Limitation

The following factors limit the HWAG:

- SYSCLK
- PCNT counter (overflow)
- Number of teeth
- Angle step

These factors will influence the engine speed range (RPM limitation) and the maximum accuracy of the angle steps (wheel limitation).

- RPM limitation

  The toothed wheel speed is limited by the period counter (PCNT) and the angle step for a given SYSCLK.

  RPM minimum is related to PCNT overflow and SYSCLK.

  Maximum PCNT value × SYSCLK = Maximum tooth period

  $$RPM = \frac{60}{TeethNumber \times ToothPeriod}$$

  PCNT is a 24-bit counter based on SYSCLK.

  RPM maximum is related to the angle step and SYSCLK.

  Minimum tooth period > Step Width × SYSCLK

  The angle ticks period could not be inferior to the SYSCLK.

  Example: The toothed wheel is a 60-2, SYSCLK is 50 Mhz (20 ns), and step width is 512:

  RPM minimum ≥ 16 777 215 × 20 ns = 335.5443 ms ≥ ~3 RPM

  RPM maximum ≥ 512 × 20 ns = 10.24 µs ≥ 97 656 RPM

  NOTE: With a 60-2 toothed wheel, the tooth period is the reverse of the RPM number.

- Wheel Limitation

  The HWAG is limited by the number of teeth and the increments in a revolution.

  The maximum number of teeth is 256. This limits the number of increments per revolution to 512 steps × 256 teeth = 131 072 angle increments.

Copyright © 2018, Texas Instruments Incorporated

23.3.2.5.2 HWAG-NHET Limitation

The maximum angle accuracy is a function of the angle step and the NHET loop resolution.

The increment per resolution limits the interface between the HWAG and the NHET. The maximum angle increment per NHET resolution is 15 increments/NHET_res, which is an angular speed. If the angle increment overflows 15 during a constant speed, the system is diverging.

In the HWAG, the angular speed is given by the relation:

$$\text{Angular Speed} = \frac{\text{Step Width}}{\text{Minimum Tooth Period}}$$

To ensure that the values are correct, they must satisfy the following equation:

$$\frac{\text{Max HET resolution} \times \text{Step Width}}{\text{Minimum Tooth Period}} < 15$$

Then,

$$\text{Max HET resolution} = \frac{15 \times \text{Min Tooth Period}}{\text{Step Width}}$$

Example: For a 60-2 at 10000 RPM, the tooth period is 100 µs and the step width is 512:

$$\text{Max HET resolution} = \frac{15 \times 100}{512} = 2.93\,\mu s$$

Copyright © 2018, Texas Instruments Incorporated

23.3.2.6 Tricks

23.3.2.6.1 Using HWAG Previous Tooth Period Value Register (HWAPCNT1)

The HWAG previous tooth period value register (HWAPCNT1) can compensate for errors because of acceleration or deceleration.

If there is a variation of the toothed wheel, the ACNT register will have a discontinuity . For an explanation of acceleration and deceleration, see Section 23.3.2.2.1.3. Avoid this discontinuity by giving the HWAPCNT1 register a smaller or larger value, depending of the variation. When HWAPCNT1 is modified, the angle tick period is also be modified which causes faster or slower tick generation and decreases the discontinuity on the next falling edge.

Because of this compensation, the NHET interface will not overflow and fewer errors will occur on the NHET angle counter in case of strong acceleration.

NOTE: Reading the angle increment will give the application the amount of the acceleration. However, adding the value directly to the NHET counter will result in a discontinuity in the compare sequence. Particularly angle based compare could be missed.

23.3.2.6.2 Using the Singularity During Normal Tooth Interrupt

This interrupt detects if the HWAG is desynchronized with the toothed wheel and resynchronizes the HWAG.

Because the criteria was set during a tooth other than the singularity tooth, the interrupt occurs. Because the criteria is based on PCNT > 2 × PCNT (n-1), this interrupt is likely due to the singularity.

The following steps explain how to resynchronize the HWAG with this interrupt:

1. Stop the HWAG
2. Reset ACNT
3. Reset tooth counter
4. Reset interrupt
5. Set start bit.

The HWAG will restart on the tooth zero.

Table 23-16. Global Configuration Register (HETGCR) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	HET_PIN_ENA		Enables the output buffers of the pin structures depending on the value of nDIS and DIR.x when PINDIS.x is set.
			Note: This bit will automatically get cleared when nDIS pin (input port) value is 0.
		0	No affect on the pin output buffer structure.
		1	Enables the pin output buffer structure when DIR = output, PINDIS.x is set and nDIS = 1.
23	Reserved	0	Reads return 0. Writes have no effect.
22-21	MP		Master Priority
			The NHET can prioritize master accesses to N2HET RAM between the HET Transfer Unit and another arbiter, which outputs the access of one of the remaining masters. The MP bits allow the following selections:
		0	The HTU has lower priority to access the N2HET RAM than the arbiter output.
		1h	The HTU has higher priority to access the N2HET RAM than the arbiter output.
		2h	The HTU and the arbiter output use a round robin scheme to access the N2HET RAM.
		3h	Reserved
20-19	Reserved	0	Reads return 0. Writes have no effect.
18	PPF		Protect Program Fields
			The PPF bit together with the Turn On/Off bit (TO) allows to protect the program fields of all instructions in N2HET RAM.
			When TO = 0:
		0	All masters can read and write the program fields.
		1	All masters can read and write the program fields.
			When TO = 1:
		0	All masters can read and write the program fields.
		1	The program fields are readable but not writable for all masters, which could access the N2HET RAM. Possible masters are the CPU, HTU, DMA and a secondary CPU (if available). Writes initiated by these masters are discarded.
17	IS		Ignore Suspend
			When Ignore Suspend = 0, the timer operation is stopped on suspend (the current timer instruction is completed). Timer RAM can be freely accessed during suspend. When set to 1, the suspend is ignored and the N2HET continues operating.
		0	N2HET stops when in suspend mode.
		1	N2HET ignores suspend mode and continues operation.

Copyright © 2018, Texas Instruments Incorporated

Table 23-16. Global Configuration Register (HETGCR) Field Descriptions (continued)

Bit	Field	Value	Description
16	CMS		Clk_master/slave
			This bit is used to synchronize multi-N2HETs. If set (N2HET is master), the N2HET outputs a signal to synchronize the prescalers of the slave N2HET. By default, this bit is reset, which means a slave configuration.
			Note: This bit must be set to one (1) for single-N2HET configuration.
		0	N2HET is configured as a slave.
		1	N2HET is configured as a master.
15-1	Reserved	0	Reads return 0. Writes have no effect.
0	TO		Turn On/Off
			TO does not affect the state of the pins. You must set/reset the timer pins when they are turned off, or re-initialize the timer RAM and control registers before a reset. After a device reset, the timer is turned off by default.
		0	N2HET is OFF. The timer program stops executing. Turn-off is automatically delayed until the current timer program loop is completed. Turn-off does not affect the content of the timer RAM, ALU registers, or control registers. Turn-off resets all flags.
		1	N2HET is ON. The timer program execution starts synchronously to the Loop clock. In case of multiple N2HETs configuration, the slave N2HETs are waiting for the loop clock to come from the master before starting execution. Then, the timer address points automatically address 00h (corresponding to program start).

Bit	Field	Value	Description
31-6	Reserved	0	Reads return 0. Writes have no effect.
5-0	OFFSET1		OFFSET1 indexes the currently pending high-priority interrupt. Offset values and sources are listed in Table 23-20. Read: Read of these bits determines the pending N2HET interrupt. Write: Writes have no effect. **Note:** In any read operation mode, the corresponding flag (in the HETFLG) is also cleared. In Emulation mode the corresponding flag is not cleared.

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 23-22. Interrupt Enable Set Register (HETINTENAS) Field Descriptions

Bit	Field	Value	Description
31-0	HETINTENAS[n]		Interrupt Enable Set bits. HETINTENAS is readable and writable in any operation mode. Writing a 1 to bit x enables the interrupts of the N2HET instructions at N2HET addresses x+0, x+32, x+64, and so on. Generating an interrupt requires to set bit x in HETINTENAS and to enable the interrupt bit in one of the instructions at addresses x+0, x+32, x+64, and so on. To avoid ambiguity, only one of the instructions x+0, x+32, x+64, and so on, should have the interrupt enable bit (inside the instruction) set. Writing a 0 to HETINTENAS has no effect. When reading from HETINTENAS bit x gives the information, if N2HET instructions x+0, x+32, x+64, and so on, have the interrupt enabled or disabled.
		0	Read: Interrupt is disabled. Write: Writes have no effect.
		1	Read: Interrupt is enabled. Write: Interrupt is enabled.

23.4.7 Interrupt Enable Clear Register (HETINTENAC)

N2HET1: offset = FFF7 B818h; **N2HET2:** offset = FFF7 B918h

Table 23-23. NHET Interrupt Enable Clear (HETINTENAC) Field Descriptions

Bit	Field	Value	Description
31-0	HETINTENAC[n]		Interrupt Enable Clear bits. HETINTENAC is readable and writable in any operation mode. Writing a 1 to bit x disables the interrupts of the N2HET instructions at N2HET addresses x+0, x+32, x+64, and so on. (See also description in Table 23-22). Writing a 0 to HETINTENAC has no effect. When reading from HETINTENAC bit x gives the information, if N2HET instructions x+0, x+32, x+64, and so on, have the interrupt enabled or disabled.
		0	Read: Interrupt is disabled. Write: Writes have no effect.
		1	Read: Interrupt is enabled. Write: Interrupt is disabled.

Table 23-27. Interrupt Flag Register (HETFLG) Field Descriptions

Bit	Field	Value	Description
31-0	HETFLAG[n]		Interrupt Flag Register Bits
			Bit x is set when an interrupt condition has occurred on one of the instructions x+0, x+32, x+64, and so on. The flag position x (in the register) is decoded from the five LSBs of the instruction address that generated the interrupt. The hardware will set the flag only if the interrupt enable bit (in the corresponding instruction) is set. The flag will be set even if bit x in the Interrupt Enable Set Register (HETINTENAS) is not enabled. Enabling bit x in HETINTENAS is required if an interrupt should be generated.
			Clearing the flag can be done by writing a one to the flag. Alternatively reading the corresponding Offset Index Priority Level 1 Register (HETOFF1) or Offset Index Priority Level 2 Register (HETOFF2) will automatically clear the flag.
		0	Read: No N2HET instruction with an interrupt has been reached since the flag was cleared.
			Write: No effect.
		1	Read: A N2HET instruction with an interrupt has been reached since the flag was cleared.
			Write: Clears the bit.

Table 23-39. N2HET Open Drain Register (HETPDR) Field Descriptions

Bit	Field	Value	Description
31-0	HETPDR[n]		Open drain control for HET[n] pins
		0	The pin is configured in push/pull mode.
		1	The pin is configured in open drain mode. The HETDOUT register controls the state of the output buffer:
			HETDOUT[n] = 0 The output buffer of pin HET[n] is driven low.
			HETDOUT[n] = 1 The output buffer of pin HET[n] is tristated.

23.4.24 N2HET Pull Disable Register (HETPULDIS)

Values in this register enable or disable the pull-up/-down functionality of the pins.
N2HET1: offset = FFF7 B864h; **N2HET2:** offset = FFF7 B964h

Figure 23-79. N2HET Pull Disable Register (HETPULDIS)

Table 23-41. N2HET Pull Select Register (HETPSL) Field Descriptions

Bit	Field	Value	Description
31-0	HETPSL[n]		Pull select for NHET pins
		0	The pull down functionality is enabled if corresponding bit in HETPULDIS is 0.
		1	The pull up functionality is enabled if corresponding bit in HETPULDIS is 0.

NOTE: See device data sheet for which pins provide programmable pullups/pulldowns.

Table 23-9 shows how the register bits of HETDIR, HETPULDIS and HETPSL are affecting the N2HET pins.

The information of this register is also used to define the pin states after a parity error:

After a parity error all N2HET pins, which are

1. Defined as output pins in the HETDIR register
2. Not defined as open drain pins (with the HETPDR register)
3. Selected with the HETPPR register, will remain outputs, but automatically change their levels in the following way:
   - If the HETPSL register specifies 0 for the pin, it will switch to low level.
   - If the HETPSL register specifies 1 for the pin, it will switch to high level.

This behavior is independent of the value, which register HETPULDIS specifies for the corresponding pin.

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 23-42. Parity Control Register (HETPCR) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reads return 0. Writes have no effect.
8	TEST		Test Bit. When this bit is set, the parity bits are mapped into the peripheral RAM frame to make them accessible by the CPU.
		0	Read: Parity bits are not memory mapped. Write: Disable mapping.
		1	Read: Parity bits are memory mapped. Write: Enable mapping.
7-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	PARITY_ENA		Enable/disable parity checking. This bit field enables or disables the parity check on read operations and the parity calculation on write operations. If parity checking is enabled and a parity error is detected the N2HET_UERR signal is activated.
		5h	Read: Parity check is disabled. Write: Disable checking.
		Others	Read: Parity check is enabled. Write: Enable checking.

NOTE: It is recommended to write Ah to enable error detection, to guard against soft errors flipping PARITY_ENA to a disable state.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; X = Value unchanged after reset

Table 23-43. Parity Address Register (HETPAR) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reads return 0. Writes have no effect.
12-2	PAOFF		Parity Error Address Offset. This register holds the offset address of the first parity error, which is detected in N2HET RAM. This error address is frozen from being updated until it is read by the CPU. During emulation mode, this address is frozen even when read. In case of a N2HET RAM parity error, PAOFF will contain the offset address of the erroneous 32-bit N2HET RAM field counted from the beginning of the N2HET RAM. Examples: The 32-bit program field of instruction 0 will return 0, the 32-bit control field of instruction 0 will return 1, ..., the 32-bit control field of instruction 1 will return 5, and so on. Read: Returns the offset address of the erroneous 32-bit word in bytes from the beginning of the N2HET RAM. Write: Writes have no effect.
1-0	Reserved	0	Reads return 0. Writes have no effect.

NOTE: The Parity Error Address Register will not be reset, neither by PORRST nor by any other reset source.

Table 23-44. Parity Pin Register (HETPPR) Field Descriptions

Bit	Field	Value	Description
31-0	HETPPR[n]		NHET Parity Pin Select Bits. Allows HET[n] pins to be configured to drive to a known state when an N2HET parity error is detected.
		0	Pin HET[n] is not affected by the detection of an N2HET parity error.
		1	Pin HET[n] is driven to a known state when an N2HET parity error is detected. The known state is a function of bits HETDIR[n], HETPSL[n], HETPDR[n] as described in Table 23-45 (this state is also independent of HETPULDIS[n]).

Table 23-45. Known State on Parity Error

HETDIR[n]	HETPDR[n]	HETPSL[n]	Known State on Parity Error
0	x	x	High Impedance
1	0	0	Drive Logic 0
1	0	1	Drive Logic 1
1	1	x	High Impedance

Table 23-55. HWAG Global Control Register 2 (HWAGCR2) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	ARST		Angle Reset. This bit is used by the HWAG to validate the singularity when the hardware criteria is not used. The bit is cleared when the HWAG angle value register (HWAACNT) is cleared by the HWAG, when the last tooth edge occurs. If this bit is not set before the tooth edge during an singularity tooth, the HWAG generates an interruption “singularity not found”, if the interrupt is enabled.
		0	Do not reset ACNT once it reaches the angle zero point.
		1	Reset ACNT once it reaches the angle zero point.
23-18	Reserved	0	Reads return 0. Writes have no effect.
17	TED		Tooth Edge. This bit is used to select which edge of the tooth wheel must be considered as active.
		0	Falling edge
		1	Rising edge
16	CRI		Criteria enable. This bits is used to control whether the criteria are applied. You could set your own criteria filter by disabling the hardwired criteria.
		0	Criteria is disabled.
		1	Criteria is enabled.
15-9	Reserved	0	Reads return 0. Writes have no effect.
8	FIL		Input Filter Enable. This bit is used to enable the toothed wheel input filter.
		0	Filter is disabled.
		1	Filter is enabled.
7-1	Reserved	0	Reads return 0. Writes have no effect.
0	STRT		Start bit. Put the HWAG into run time. Allows the HWAG to start counting ACNT, TCNT and criteria mechanism (if set). The HWAG starts at the next active edge from the toothed wheel, once set. If the start bit is cleared to 0, the HWAG is stopped immediately.
		0	Do not start counting.
		1	Start counting.

Table 23-61. HWAG Interrupt Flag Register (HWAFLG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	INTFLG[n]		Interrupt Flag. These bit are set when an interrupt condition has occurred inside the HWAG. The interrupt is sent to the CPU if, and only if, the corresponding enable bit is set. HWAFLG is cleared by either reading the HWAOFF0 or HWAOFF1 register (if the corresponding bit is set) or by writing 1 to the bit. If HWAFLG is 1 but the corresponding interrupt is not enabled then it will not generate an interrupt, also the OFFSET index will not be generated for that particular HWAFLG bit. So, a read of HWAOFF registers will not clear a HWAFLG bit that is not enabled. See Table 23-57.
		0	Read: No interrupt is pending. Write: No effect.
		1	Read: Interrupt is pending. Write: Clear the corresponding interrupt flag.

23.5.10 HWAG Interrupt Offset Register 0 (HWAOFF0)

This register is a read-only register and provides a numerical value that represents the pending interrupt with a high priority. The index can be used to locate the interrupt routine position in the vector table. A read to this register clears the corresponding interrupt pending bit in the HWAG interrupt flag register (HWAFLG). An interrupt pending bit in the HWAFLG register is the bit for which the corresponding interrupt enable bit is set.

During suspend mode, a read to this register does not clear the corresponding interrupt bit.

23.5.11 HWAG Interrupt Offset Register 1 (HWAOFF1)

This register is a read-only register and provides a numerical value that represents the pending interrupt with a low priority. The index can be used to locate the interrupt routine position in the vector table. A read to this register clears the corresponding interrupt pending bit in the HWAG interrupt flag register (HWAFLG). An interrupt pending bit in the HWAFLG register is the bit for which the corresponding interrupt enable bit is set.

During suspend mode, a read to this register does not clear the corresponding interrupt bit.

23.6 Instruction Set

23.6.1 Instruction Summary

Table 23-73 presents a list of the instructions in the N2HET instruction set. The pages following describe each instruction in detail.

Table 23-73. Instruction Summary

Abbreviation	Instruction Name	Opcode	Sub-Opcode	Cycles[1]
ACMP	Angle Compare	Ch	-	1
ACNT	Angle Count	9h	-	2
ADCNST	Add Constant	5h	-	2
ADC	Add with Carry and Shift	4h	C[25:23] = 011, C5 = 1	1-3
ADD	Add and Shift	4h	C[25:23] = 001, C5 = 1	1-3
ADM32	Add Move 32	4h	C[25:23] = 000, C5 = 1	1-2
AND	Bitwise AND and Shift	4h	C[25:23] = 010, C5 = 1	1-3
APCNT	Angle Period Count	Eh	-	1-2
BR	Branch	Dh	-	1
CNT	Count	6h	-	1-2
DADM64	Data Add Move 64	2h	-	2
DJZ	Decrement and Jump if -zero	Ah	P[7:6] = 10	1
ECMP	Equality Compare	0h	C[6:5] = 00	1
ECNT	Event Count	Ah	P[7:6] = 01	1
MCMP	Magnitude Compare	0h	C[6] = 1	1
MOV32	Move 32	4h	C[5] = 0	1-2
MOV64	Move 64	1h	-	1
OR	Bitwise OR	4h	C[25:23] = 100, C5 = 1	1-3
PCNT	Period/Pulse Count	7h	-	1
PWCNT	Pulse Width Count	Ah	P[7:6] = 11	1
RADM64	Register Add Move 64	3h	-	1
RCNT	Ratio Count	Ah	P[7:6] = 00, P[0] = 1	3
SBB	Subtract with Borrow and Shift	4h	C[25:23] =110, C[5] = 1	1-3
SCMP	Sequence Compare	0h	C[6:5] = 01	1
SCNT	Step Count	Ah	P[7:6] = 00, P[0] = 0	3
SHFT	Shift	Fh	C[3] = 0	1
SUB	Subtract and Shift	4h	C[25:23] = 101, C[5] = 1	1-3
WCAP	Software Capture Word	Bh	-	1
WCAPE	Software Capture Word and Event Count	8h	-	1
XOR	Bitwise Exclusive-Or and Shift	4h	C[25:23] = 111, C[5] = 1	1-3

(1) Cycles refers to the clock cycle of the N2HET module; which on most devices is VCLK2. (Check the device datasheet description of clock domains to confirm). If the high-resolution prescale value is set to /1, then this is also the same as the number of HR clock cycles.

23.6.2 Abbreviations, Encoding Formats and Bits

Abbreviations marked with a star (*) are available only on specific instructions.

U Reading a bit marked with U will return an indeterminate value.

BRK Defines the software breakpoint for the device software debugger.
Default: OFF
Location: Program field [22]

next Defines the program address of the next instruction in the program flow. This value may be a label or an 9-bit unsigned integer.
Default: Current instruction + 1
Location: Program field [21:13]

reqnum* Defines the number of the request line (0,1,..,7) to trigger either the HTU or the DMA.
Default: 0
Location: Program field [25:23]

request* Allows to select between no request (NOREQ), request (GENREQ) and quiet request (QUIET). See Section 23.2.9.
Default: No request
Location: Control Field [28:27]

Request	C[28]	C[27]	To HTU	To DMA
NOREQ	0	0	no request	no request
	1	0		
GENREQ	0	1	request	request
QUIET	1	1	quiet request	no request

remote* Determines the 9-bit address of the remote address for the instruction.
Default: Current instruction + 1
Location: Program field [8:0]

control Determines whether the immediate data field [31:0] is cleared when it is read. When the bit is not set, reads do not clear the immediate data field.
Default: OFF
Location: Control field [26]

en_pin_action* Determines whether the selected pin is ON so that the action occurs on the chosen pin
Default: OFF
Location: Control field [22]

Cond_addr* Conditional address (optional): Defines the address of the next instruction when the condition occurs.
Default: Current address + 1
Location: Control field [21:13]

Pin* Pin Select: Selects the pin on which the action occurs. Enter the pin number.
Default: pin 0
Location: Control field [12:8] except PCNT

Copyright © 2018, Texas Instruments Incorporated

The format CC{pin number} is also supported.

MSB				LSB	Description
0	0	0	0	0	Select HET[0]
0	0	0	0	1	Select HET[1]
(Each pin may be selected by writing its number in binary)					
1	1	1	1	0	Select HET[30]
1	1	1	1	1	Select HET[31]

Reg* Register select: Selects the register for data comparison and storage

Default: No register (None)

Location: Control field [2:1] except for CNT instruction.

Extended Register Select C[7] is available for ACMP, ADC, ADD, ADM32, AND, DADM64, ECMP, ECNT, MCMP, MOV32, MOV64, OR, RADM64, SBB, SHFT, SUB, WCAP, WCAPE instructions.

Register	Ext Reg. C[7]	C[2]	C[1]
A	0	0	0
B	0	0	1
T	0	1	0
None	0	1	1
R	1	0	0
S	1	0	1
Reserved	1	1	0
Reserved	1	1	1

Action* (2 Action Option) Either sets or clears the pin

Default: Clear

Location: Control Field [4]

Action	C[4]
Clear	0
Set	1

Action* (4 Action Option) Either sets, clears, pulse high or pulse low on the pin. Set/clear are single pin actions, pulse high/low include the opposite pin action.

Default: Clear

Location: Control Field [4:3]

Action	Action Type	C[4]	C[3]
Clear	Set low on match	0	0
Set	Set high on match	1	0
Pulse Low	Set low on match + reset to high on Z=1 (opposite action)	0	1
Pulse High	Set high on match + reset to low on Z=1 (opposite action)	1	1

Copyright © 2018, Texas Instruments Incorporated

hr_lr* Specifies HIGH/LOW data resolution. If the hr_lr field is HIGH, the instruction uses the hr_data field. If the hr_lr field is LOW, the hr_data field is ignored.

Default: HIGH

Location: Program Field [8]

hr_lr	Prog. field [8]
LOW	1
HIGH	0

prv* Specifies the initial value defining the previous bit (see Section 23.2.5.8). A value of ON sets the previous pin-level bit to 1. A value of OFF sets the initial value of the previous (prv) bit to 0. The prv bit is overwritten (set or reset) by the N2HET the first time the instruction is executed.

Default: OFF

Location: Control Field [25]

cntl_val* Available for DADM64, MOV64, and RADM64, this bit field allows the user to specify the replacement value for the remote control field.

comp_mode* Specifies the compare mode. This field is used with the 64-bit move instructions. This field ensures that the sub-opcodes are moved correctly.

Default: ECMP

Location: Control Field [6:5]

Action	C[6]	C[5]	Order
ECMP	0	0	
SCMP	0	1	
MCMP1	1	0	REG_GE_DATA
MCMP2	1	1	DATA_GE_REG

Copyright © 2018, Texas Instruments Incorporated

23.6.3 Instruction Description

The following sections provide information for individual instructions.

Parameters in [] are optional. Refer to the N2HET assembler user guide for the default values when parameters are omitted.

23.6.3.1 ACMP (Angle Compare)

Syntax

```
ACMP {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[reqnum={3-bit unsigned integer}]
[request={NOREQ | GENREQ | QUIET}]
[control={OFF | ON}]
[en_pin_action={OFF | ON}]
[cond_addr={label | 9-bit unsigned integer}]
pin={pin number}
[action={CLEAR | SET}]
reg={A | B | R | S | T | NONE}
[irq ={OFF | ON}]
data={25-bit unsigned integer}
}
```

Figure 23-109. ACMP Program Field (P31:P0)

31–26	25–23	22	21–13	12–9	8–0

Data	Reserved
25	7

Cycles One

Register modified Selected register (A, B, R, S, or T)

Copyright © 2018, Texas Instruments Incorporated

The purpose of the comparison is to assert pin action when the angle compare value lies between the old counter value and the new counter value (held in the selected register). Since the angle increment varies from one loop resolution clock to another, an exact equality test cannot be applied. Instead, the following inequality is used to determine the occurrence of a match:

Old counter value < *Angle compare value* ≤ *New counter value*

This is done by performing following comparisons:

Selected register value minus angle increment < angle compare value
Angle compare value ≤ Selected register value

register	Register B is recommended for typical applications with ACMP.
irq	Specifies whether or not an interrupt is generated. Specifying ON generates an interrupt when the edge state is satisfied and the gap flag is set. Specifying OFF prevents an interrupt from being generated. Default: OFF.
data	Specifies the 25-bit angle compare value.

Execution

```
X = 0;
If (Data <= Selected Register)
      Cout = 0;
else
      Cout = 1;
If (Z == 0 AND (Selected Register - Angle Inc. < Data ) AND Cout == 0) OR

 (Z == 1 AND (Cout_prv == 1 OR Cout == 0)))
{
      X = 1;
      If (Enable Pin Action == 1)
          Selected Pin = Pin Action AT next loop resolution clock;

      If (Interrupt Enable == 1)
          HETFLG[n] = 1;   /* n depends on address */
      If ([C28:C27] == 01)
          Generate request on request line [P25:P23];
      If ([C28:C27] == 11)
          Generate quiet request on request line [P25:P23];

      Jump to Conditional Address;
 }

 else
      Jump to Next Program Address;

Cout_prv = Cout (always executed)
```

NOTE: Carry-Out Signal (Cout)

Cout is the carry-out signal of the adder. Even if it is not a flag, it is valid all along ACMP instruction execution.

Angle inc. = NAF_global or hardware angle generator 11-bit input.

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see Section 23.2.7.

Copyright © 2018, Texas Instruments Incorporated

23.6.3.2 ACNT (Angle Count)

Syntax

```
ACNT {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[reqnum={3-bit unsigned integer}]
[request={NOREQ | GENREQ | QUIET}]
edge={RISING | FALLING}
[irq ={OFF | ON}]
[control={OFF | ON}]
[prv={OFF | ON}]
gapend ={25-bit unsigned integer}
data={25-bit unsigned integer}
}
```

Figure 23-112. ACNT Program Field (P31:P0)

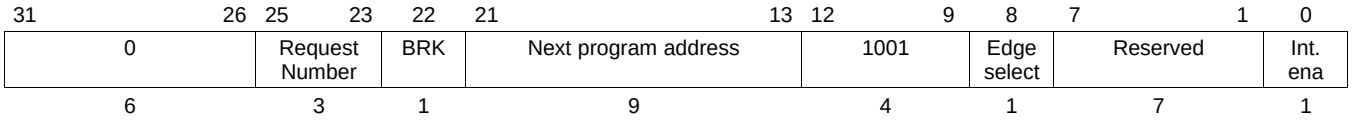

Figure 23-113. ACNT Control Field (C31:C0)

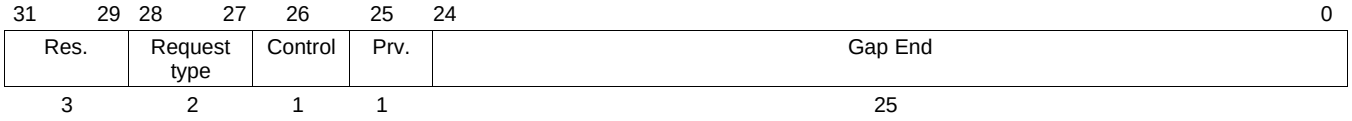

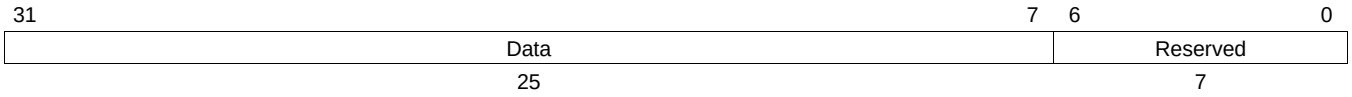

Figure 23-114. ACNT Data Field (D31:D0)

Cycles

Two, as follows:

- First cycle: Angle increment condition and gap end comparison.
- Second cycle: Gap start comparison.

Register modified

Register B (angle value)

Description

This instruction defines a specialized virtual timer used after SCNT and APCNT to generate an angle-referenced time base that is synchronized to an external signal (that is, a toothed wheel signal). ACNT uses pin HET[2] exclusively. The edge select must be the same as the HET[2] edge which was selected in the previous APCNT.

ACNT refers to the same step width selection that the previous SCNT saved in flags SWF0 and SWF1 (see information on SCNT).

ACNT detects period variations of the external signal measured by APCNT and compensates related count errors.

Copyright © 2018, Texas Instruments Incorporated

A period increase is flagged in the deceleration flag (DCF). A period decrease is flagged in the acceleration flag (ACF). If no variation is detected, ACNT increments the counter value each time SCNT reaches its target.

If acceleration is detected, ACNT increments the counter value on each timer resolution. If deceleration is detected ACNT does not increment and is thus saturated.

ACNT also specifies the gap end angle value defining the end value of a gap range in ACNT where period measurements in APCNT are temporarily stopped to mask singularities in the external signal. ACNT uses register A containing gap start and register B to store the counter value.

Edge Specifies the edge for the input capture pin (HET[2]).

Action	P8	Edge Select
Rising	1	Detects a rising edge of HET[2]
Falling	0	Detects a falling edge of HET[2]

irq ON generates an interrupt when the edge state is satisfied and the gap flag is set. OFF prevents an interrupt from being generated.

Default: OFF.

gapend Defines the 25-bit end value of a gap range. The start value is defined in the SCNT instruction.

GAPEND = (Step Value * (# of teeth on the toothed wheel + # of missing teeth)) - 1

data Specifies the 25-bit initial count value for the data field.

Default: 0.

NOTE: Target Edge Field

The target edge field represents the three LSBs of data field register in case of step width = 8, four LSBs for step width = 16, five LSBs for step width = 32 and six LSBs for step width = 64.

Execution

```
Increment Condition: ((Z = 1 AND DCF = 0) OR ACF = 1)
Pin Edge Condition: Specified edge detected on HET[2]
Target Edge Condition: (Target Edge field in data field = 0) AND (Angle
Increment condition is true) AND (GPF = 0)

If (Angle Increment Condition) is false
{
      NAF = 0;
      Register B = Data field register;
}
else
{
      NAF = 1;
      If (Counter value != GapEnd)
      {
           Register B = Data field register + 1;
           Data Field Register = Counter value + 1;
      }
```

23.6.3.3 ADCNST (Add Constant)

Syntax

```
ADCNST {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[control={OFF | ON}]
remote={label | 9-bit unsigned integer}
min_off={25-bit unsigned integer}
data={25-bit unsigned integer}
[hr_data={7-bit unsigned integer}]
}
```

Figure 23-115. ADCNST Program Field (P31:P0)

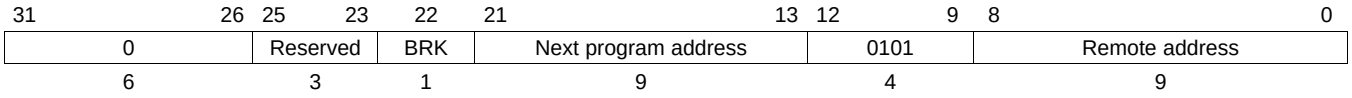

Figure 23-116. ADCNST Control Field (C31:C0)

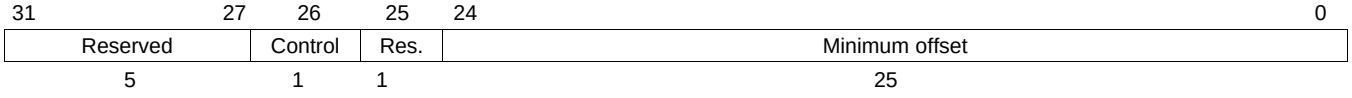

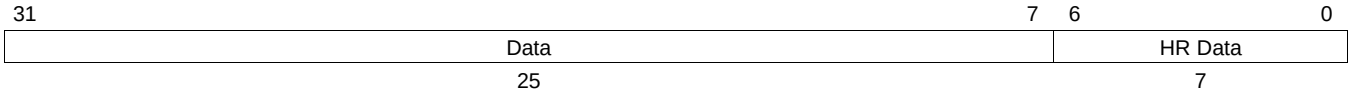

Figure 23-117. ADCNST Data Field (D31:D0)

Cycles Two

Register modified Register T (implicity)

Description ADCNST is an extension of ADM32. ADCNST first checks whether the data field value at the remote address is zero; it then performs different adds and moves on the result. ADCNST is typically used to extend the counter value of PWCNT.

min_off A 25-bit constant value that is added to the data field value if the remote data field is null.

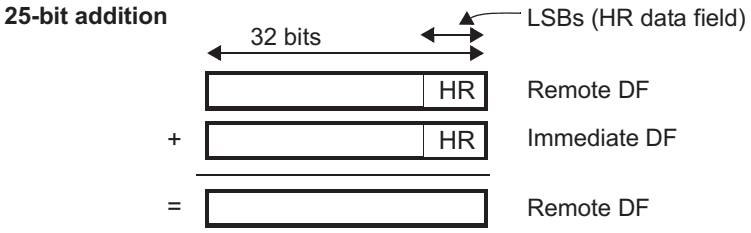
data A 25-bit value that is always added to the remote data field.
Default: 0.

hr_data Seven least significant bits of the data addition to the remote data field.
Default: 0.

Copyright © 2018, Texas Instruments Incorporated

Figure 23-118 and Figure 23-119 illustrate the behavior of ADCNST if the remote data field is zero or is not zero.

Figure 23-118. ADCNST Operation If Remote Data Field[31:7] Is Not Zero



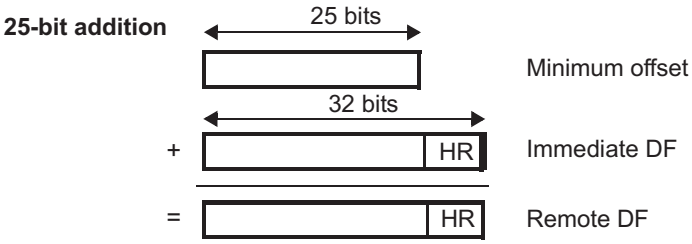


Figure 23-119. ADCNST Operation if Remote Data Field [31:7] Is Zero

Execution

```
If (Remote Data Field Value [31:7] != 0)
      Remote Data Field = Immediate Data Field + Remote Data Field;
else
      Remote Data Field = Immediate Data Field + min. offset(bits C24:C0);

Cycles One to three cycles, depending on operands selected. (See Table 23-80)

Register modified Selected register (A, B, R, S, T, or NONE)

Description This instruction performs the specified 32-bit arithmetic or logical operation on operands src1 and src2, followed by an optional shift/rotate step. The result of this operation is then stored to either an N2HET register or the immediate data field of the instruction. In addition, the same result may be stored in a remote data field or the least signficant bits of a remote instruction program field (P[8:0]). Bits P[8:0] of the program field are used by most instructions formats to hold the remote address that the instruction operates on, so the ability to update this field programatically makes it easier to write subroutines that operate on different data sets.

Copyright © 2018, Texas Instruments Incorporated

The Sub-Opcode field C[25:3] determines which type of operation (ADD, ADC, AND, OR, SBB, SUB, XOR) is executed by the instruction. A list of these operations and the corresponding Sub-Opcode encoding can be found in Table 23-76.

All arithmetic is performed using 32-bit integer math. However, source and destination operands vary in width and can be 9 bits (REMP), 25 bits (A, B) or 32 bits (R,S,T, IMM, REM). Source operands REMP, A,B are extended to 32-bits before being operated on. Also the result of the computation needs to be truncated before being written back to REMP, A, or B when these are selected as destination operands. Table 23-77 provides a list of source operand options, how they are expanded to 32-bit integers (if applicable) and the control field encoding to select the option for src1 and src2 operands.

Table 23-78 provides a similar list of destination operands and their encodings. Up to two destination operands may be selected for each instruction, a register/immediate destination and a remote destination may be selected simultaneously. Truncation is performed independently for each destination operand as appropriate to its size.

An optional shift step following the arithmetic or logical operation may be selected through the smode and scount operands. The shift or rotate type is selected by the smode field; Table 23-79 illustrates the options that are available for smode. The number of bits shifted is determined by the scount operand.

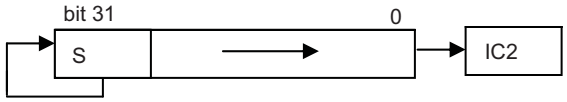
Table 23-76. Arithmetic / Bitwise Logic Sub-Opcodes

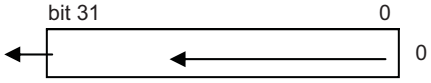
Instruction	Description	Operation	Sub-Opcode
ADC	Add with Carry	result = src1 + src2 + C	C[25:23] = 011
ADD	Add	result = src1 + src2	C[25:23] = 001
AND	Bitwise Logic And	result = src1 & src2	C[25:23] = 010
OR	Bitwise Logic Or	result = src1 | src2	C[25:23] = 100
SBB	Subtract with Borrow	result = src1 - src2 - C	C[25:23] = 110
SUB	Subtract	result = src1 - src2	C[25:23] = 101
XOR	Bitwise Logic Exclusive Or	result = src1 ^ src2	C[25:23] = 111

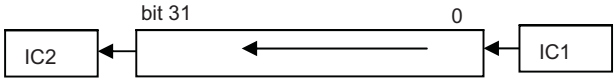
Table 23-77. Source Operand Choices

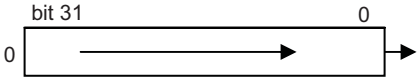
Source Operand	32-bit value	Address	src1	src2
A	{A[24:0], 0x00}	n/a	C[22:19] = 0010	C[18:16] = 010
B	{B[24:0], 0x00}	n/a	C[22:19] = 0011	C[18:16] = 011
R	R[31:0]	n/a	C[22:19] = 0100	C[18:16] = 100
S	S[31:0]	n/a	C[22:19] = 0101	C[18:16] = 101
T	T[31:0]	n/a	C[22:19] = 0110	C[18:16] = 110
IMM	D[31:0]	current instruction address	C[22:19] = 0001	C[18:16] = 001
ZERO	0x00000000	n/a	C[22:19] = 0000	C[18:16] = 000
ONES	0xFFFFFFFF	n/a	C[22:19] = 0111	C[18:16] = 111
REM	D[31:0]	specified by remote[8:0]	C[22:19] = 1000	n/a
REMP	{0x000000, P[8:0]}	specified by remote[8:0]	C[22:19] = 1001	n/a

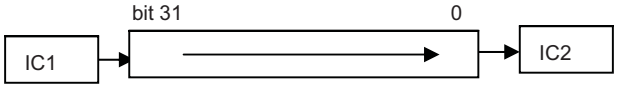
Table 23-78. Destination Operand Choices

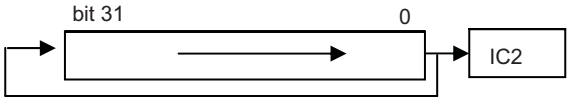


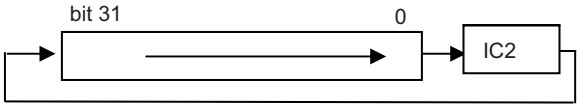












Destination Operand	Stored Value	Address	dest	rdest
A	A[24:0] = result [31:8]	n/a	C[7] = 0, C[2:1] = 00	n/a
B	B[24:0] = result [31:8]	n/a	C[7] = 0, C[2:1] = 01	n/a
R	R[24:0] = result [31:0]	n/a	C[7] = 1, C[2:1] = 00	n/a
S	S[24:0] = result [31:0]	n/a	C[7] = 1, C[2:1] = 01	n/a
T	T[24:0] = result [31:0]	n/a	C[7] = 0, C[2:1] = 10	n/a

Table 23-78. Destination Operand Choices (continued)

Destination Operand	Stored Value	Address	dest	rdest
IMM	D[31:0] = result [31:0]	current instruction address	C[7] = 1, C[2:1] = 10	n/a
NONE	n/a	n/a	C[7] = 0, C[2:1] = 11	C[4:3] = 00
REM	D[31:0] = result [31:0]	specified by remote[8:0]	n/a	C[4:3] = 01
REMP	P[8:0] = result [8:0]	specified by remote[8:0]	n/a	C[4:3] = 10

Table 23-79. Shift Encoding

Shift Type	C[15:13] smode	Operation Illustrated (1)
No Shift Applied	0 0 0	n/a - no shift
ASR-Arithmetic Shift Right	0 0 1	
LSL-Logical Shift Left	0 1 0	
CSL-Carry Shift Left	0 1 1	
LSR-Logical Shift Right	1 0 0	
CSR-Carry Shift Right	1 0 1	
RR - Rotate Right	1 1 0	
CRR – Carry Rotate Right	1 1 1	

(1) IC1 is the carry flag after the arithmetic / logical operation is performed. Ic2 is the updated carry flag after the shift operation is performed. s is the sign bit.

Table 23-80. Execution Time for ADC, ADD, AND, OR, SBB, SUB, XOR Instructions

src1	dest	rdest	remote[8:0]	Cycles

Data	HR Data
25	7

Cycles One or two cycles (see Table 23-81)

Register modified Selected register (A, B, R, S, or T)

Description This instruction modifies the selected ALU register or data field values at the remote address depending on the move type. The modified value results from adding the immediate or remote data field to the ALU register or the remote data field, depending on the move type. Table description shows the C2 and C1 bit encoding for determining which register is selected.

init (Optional) Determines whether or not system flags are initialized. A value of ON reinitializes the following system flags to these states:

Acceleration flag (ACF) = 0

Deceleration flag (DCF) = 1

Gap flag (GPF) = 0

Copyright © 2018, Texas Instruments Incorporated

New angle flag (NAF) = 0
A value of OFF results in no change to the system flags.
Default: OFF

type Specifies the move type to be executed.

Table 23-81. Move Types for ADM32

Type	C4	C3	Add	Destination(s)	Cycles
IM&REGTOREG	0	0	Imm. data field + Reg. A, B, R, S, or T	Register A, B, R, S, or T	1
REM&REGTOREG	0	1	Remote data field + Reg. A, B, R, S, or T	Register A, B, R, S, or T	2
IM&REMTOREG	1	0	Imm. data field + Remote data field	Register A, B, R, S, or T	2
IM&REGTOREM	1	1	Imm. data field + Reg. A, B, R, S, or T	Remote data field	1

If selected register is R, S, or T, the operation is a 32-bit Addition/move. If A or B register is selected, it is limited to 25-bit operation since A and B only support 25-bit.

data Specifies the 25-bit integer value for the immediate data field.

hr_data Specifies the 7 least significant bits of the immediate data field.
Default: 0.

Execution

```
switch (C4:C3)
{
      case 00:
           Selected register = Selected register + Immediate Data Field;
      case 01:
           Selected register = Selected register + Remote Data Field;
      case 10:
           Selected register = Immediate Data Field + Remote Data Field;
      case 11:
           Remote Data Field = Selected register + Immediate Data Field;
}

If (Init Flag == 1)
{
      ACF = 0;
      DCF = 1;
      GPF = 0;
      NAF = 0;
}
else
      All flags remain unchanged;

Cycles

One or two cycles

- Cycle 1: edge detected (normal operation)
- Cycle 2: edge detected and GPF = 1 and underflow condition is true

One cycle (normal operation) two cycles (edge detected)

Register modified

Register A and T (implicitly)

Description

This instruction is used before SCNT and ACNT to generate an angle-referenced time base synchronized to an external signal (that is, a toothed wheel signal). It is assumed that the pin and edge selections are the same for APCNT and ACNT.

APCNT is restricted to pin HET[2]. The toothed wheel must then be connected to pin HET[2].

APCNT uses the gap flag (GPF) defined by ACNT to start or stop captures in the period count field [C24:C0]. When GPF = 1, the previous period value is held in the control field and in register T. When GPF = 0, the current period value is captured in the control field and in register T.

Copyright © 2018, Texas Instruments Incorporated

APCNT uses the step width flags (SWF0 and SWF1) defined by SCNT to detect period durations shorter than one step, and then disables capture.

The edge select encoding is shown in Table 23-82.

irq ON generates an interrupt when the edge state is satisfied. OFF prevents an interrupt from being generated.
Default: OFF.

type Specifies the edge type that triggers the instruction.
Default: Fall2Fall.

Table 23-82. Edge Select Encoding for APCNT

type	P7	P6	Selected Condition
Fall2Fall	1	0	Falling edge
Rise2Rise	1	1	Rising edge

period Contains the 25-bit count value from the previous APCNT period.

data 25-bit value serving as a counter.
Default: 0.

Copyright © 2018, Texas Instruments Incorporated

Execution

```
Z = 0;

If (Data field register != 1FFFFFFh)
{
   Register A = Data field register + 1;
   Data field register = Data field register + 1;
}
elseIf (specified edge not detected on HET[2])
{
   Register A = 1FFFFFFh;
   APCNT Ovflw flag = 1;
}

If (specified edge detected on HET[2])
{
   Z = 1;

   If (Data field register == 1FFFFFFh)
   {
      Register A = 1FFFFFFh;
      Register T = 1FFFFFFh;Period count = 1FFFFFFh;
      Period count = 1FFFFFFh;
   }
   elseIf (GPF == 0 AND Data Field register >= Step width)
   {
      Register A = Data field register + 1;
      Register T = Register A;
      Period count = Register T;

      If (Interrupt Enable == 1)
         HETFLG[n] = 1;      /* n depends on address */
      If ([C28:C27] == 01)
         Generate request on request line [P25:P23];
      If ([C28:C27] == 11)
         Generate quiet request on request line [P25:P23];
   }

   If (GPF == 1)
         Register T = Period count;
   If (Data Field register < Step width)
   {
      Register T = Period count;
      APCNT Undflw flag = 1;
      Period Count = 000000h;
   }

   Data field register = 000000h;
}
else
{
      Register T = Period count;
}

Prv bit = Current Lx value of HET[2] pin;

Jump to Next Program Address;
```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see Section 23.2.7.

23.6.3.8 CNT (Count)

Syntax

```
CNT {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[reqnum={3-bit unsigned integer}]
[request={NOREQ | GENREQ | QUIET}]
[angle_count={OFF | ON}]
[reg={A | B | T | NONE}]
[comp ={EQ | GE}]
[irq={OFF | ON}]
[control={OFF | ON}]
max={25-bit unsigned integer}
[data={25-bit unsigned integer]
}
```

Figure 23-134. CNT Program Field (P31:P0)

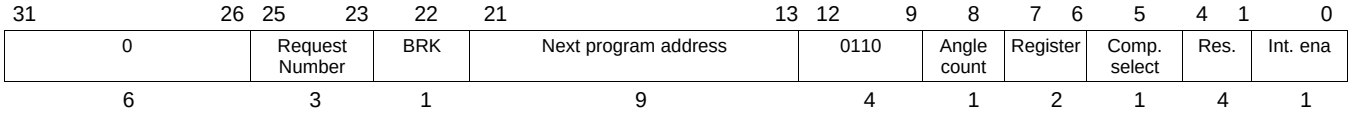

Figure 23-135. CNT Control Field (C31:C0)

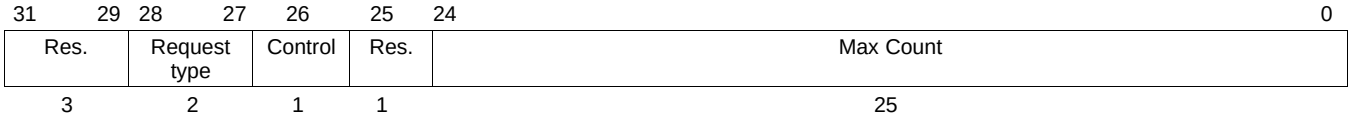

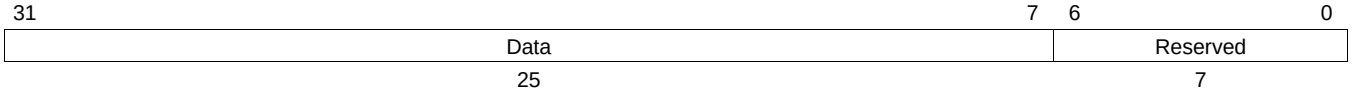

Figure 23-136. CNT Data Field (D31:D0)

Cycles

One or two

One cycle (time mode), two cycles (angle mode)

Register modified

Selected register (A, B or T)

Description

This instruction defines a virtual timer. The counter value stored in the data field [D31:7] is incremented unconditionally on each execution of the instruction when in time mode (angle count bit [P8] = 0). When the count reaches the maximum count specified in the control field, the counter is reset. It takes one cycle in this mode.

In angle mode (angle count bit [P8] = 1), CNT needs data from the software angle generator (SWAG). When in angle count mode the angle increment value will be 0 or 1. It takes two cycles in this mode.

Copyright © 2018, Texas Instruments Incorporated

angle_count	Specifies when the counter is incremented. A value of ON causes the counter value to be incremented only if the new angle flag is set (NAF_global = 1). A value of OFF increments the counter each time the CNT instruction is executed. Default value for this field is OFF.
comp	When set to EQ the counter is reset, when it is equal to the maximum count. When set to GE the counter is reset, when it is greater or equal to the maximum count. Default: GE.
irq	ON generates an interrupt when the counter overflows to zero. The interrupt is not generated until the data field is reset to zero. If irq is set to OFF, no interrupt is generated. Default: OFF.
max	Specifies the 25-bit integer value that defines the maximum count value allowed in the data field. When the count in the data field is equal to max, the data field is reset to 0 and the Z system flag is set to 1.
data	Specifies the 25-bit integer value serving as a counter. Default: 0.

Copyright © 2018, Texas Instruments Incorporated

Execution

```
Z = 0;

If (Angle Count (bit P8 == 1))
{
   If (NAF_global == 0)
   {
      Selected register = immediate data field;
      Jump to Next Program Address;
   }
   else
   {
      If ((Immediate Data Field + Angle Increment) >= Max count)
      {
         Z = 1;
         Selected register = ((Immediate Data Field + Angle Inc.) - Max count);
         Immediate Data Field = ((Immediate Data Field + Angle Inc.) - Max count);

         If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
         If ([C28:C27] == 01) Generate request on request line [P25:P23];
         If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];
      }
      else
      {
         Selected register = Immediate Data Field + Angle Increment;
         Immediate Data Field = Immediate Data Field + Angle Increment;
      }
   }
}

else if(Time mode (bit P8 == 0))
{
   If [(P5==0) AND (Immediate Data Field == Max count)]
   OR [(P5==1) AND (Immediate Data Field >= Max count)]
   {
       Z = 1;
       Selected register = 00000;
       Immediate Data Field = 00000;

       If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
       If ([C28:C27] == 01) Generate request on request line [P25:P23];
       If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];
   }
   else
   {
       Selected register = Immediate Data Field + 1;
       Immediate Data Field = Immediate Data Field + 1;
   }
}

Cycles Two

Register modified Register T (implicitly)

Description This instruction modifies the data field and the control field at the remote address. The remote data field value is not just replaced, but is added with the DADM64 data field.

DADM64 has two distinct syntaxes. In the first syntax, bit values may be set by assigning a value to each of the control fields. This syntax is convenient for modifying control fields that are arranged similarly to the format of the DADM64 control field. A second syntax, in which the entire 29-bit control field is specified by the cntl_val field, is convenient when the remote control field is dissimilar to the DADM64 control field. Either syntax may be used, but you must use one or the other but not a combination of syntaxes.

Figure 23-140 shows the DADM64 add and move operation.

Figure 23-140. DADM64 Add and Move Operation

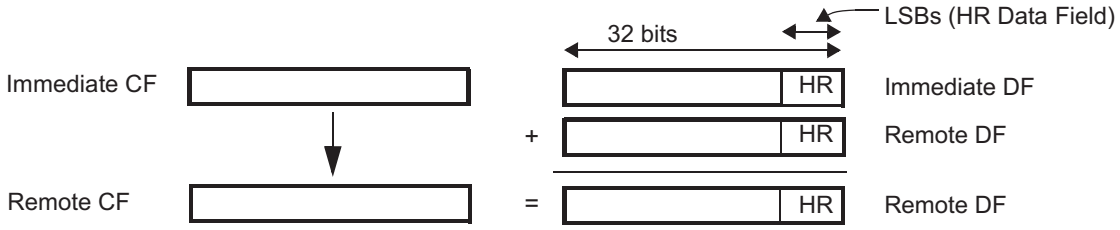

Table 23-84. DADM64 Control Field Description

request	maintains the control field for the remote instruction
control	maintains the control field for the remote instruction
en_pin_action	maintains the control field for the remote instruction
cond_addr	maintains the control field for the remote instruction

Copyright © 2018, Texas Instruments Incorporated

Table 23-84. DADM64 Control Field Description (continued)

pin	maintains the control field for the remote instruction
register	maintains the control field for the remote instruction
action	maintains the control field for the remote instruction
irq	maintains the control field for the remote instruction
data	Specifies the 25-bit initial value for the data field.
hr_data	Seven least significant bits of the 32 bit data field. Default: 0
cntl_val	Specifies the 29 least significant bits of the Control field.

Execution

```
Remote Data Field = Remote Data Field + Immediate Data Field;
Register T = Immediate Data Field;
Remote Control Field = Immediate Control Field;
Jump to Next Program Address;
```

Copyright © 2018, Texas Instruments Incorporated

23.6.3.10 DJZ (Decrement and Jump if Zero)

DJNZ is also a supported syntax. The functionality of the two instruction names is identical.

Syntax

```
DJZ {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[reqnum={3-bit unsigned integer}
[request={NOREQ | GENREQ | QUIET}]
[control={OFF | ON}]
[cond_addr={label | 9-bit unsigned integer}]
[reg={A | B | T | NONE}]
[irq={OFF | ON}]
[data={25-bit unsigned integer]
}
```

Figure 23-141. DJZ Program Field (P31:P0)

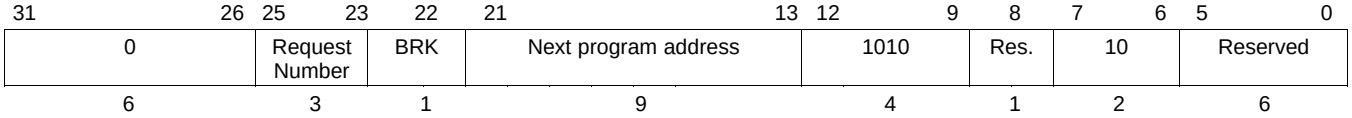

Figure 23-142. DJZ Control Field (C31:C0)

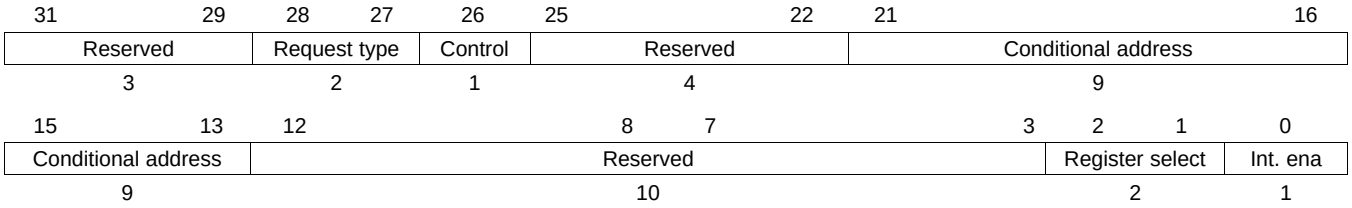

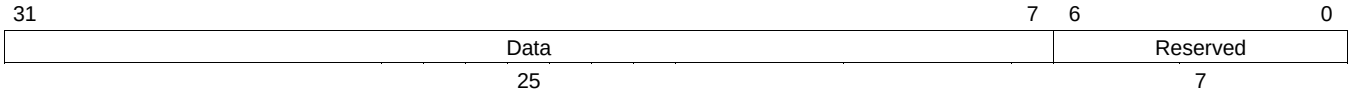

Figure 23-143. DJZ Data Field (D31:D0)

Cycles One

Register modified Selected register (A, B, or T)

Description This instruction defines a virtual down counter used for delayed execution of certain instructions (to generate minimum on/off times). When DJZ is executed with counter value not zero, the counter value is decremented. If the counter value is zero, the counter remains zero until it is reloaded with a non-zero value. The program flow can be modified when down counter value is zero by using the conditional address.

Copyright © 2018, Texas Instruments Incorporated

cond_addr	This field is not optional for the DJZ instruction.
irq	ON generates an interrupt when the data field reaches zero. No interrupt is generated when the bit is OFF. Default: OFF.
data	Specifies the 25-bit integer value used as a counter. This counter is decremented each time the DJZ instruction is executed until the counter reaches 0. Default: 0.

Execution

```
If (Data != 0)
{
   Data = Selected register = Data - 1;
   Jump to Next Program Address;
}
else
{
   Selected register = 000000h;

   If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
   If ([C28:C27] == 01) Generate request on request line [P25:P23];
   If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];

   Jump to conditional Address;
}
```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see Section 23.2.7.

Copyright © 2018, Texas Instruments Incorporated

23.6.3.11 ECMP (Equality Compare)

Syntax

```
ECMP {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[reqnum={3-bit unsigned integer}
[request={NOREQ | GENREQ | QUIET}]
[hr_lr={HIGH | LOW}]
[angle_comp={OFF | ON}]
[control={OFF | ON}]
[en_pin_action={OFF | ON}]
[cond_addr={label | 9-bit unsigned integer}]
pin={pin number}
[action={CLEAR | SET | PULSELO | PULSEHI}]
[reg={A | B | R | S| T | NONE}]
[irq={OFF | ON}]
[data={25-bit unsigned integer]
[hr_data={7-bit unsigned integer}]
}
```

Cycles	One
Register modified	Register A, B, R, S or T if selected
Description	ECMP can use all pins. This instruction compares a 25-bit data value stored in the data field (D31–D7) to the value stored in the selected ALU register (A, B, R, S, or T). Register select encoding can be found in Section 23.6.2. If R, S, or T registers are selected, and if the 25-bit data field matches, ECMP updates the register with the 32-bit value (D31-D0). If the hr_lr bit is cleared, the pin action will occur after a high resolution delay from the next loop resolution clock. If the hr_lr bit is set, the delay is ignored. This delay is programmed in the data field (D6–D0). The behavior of the pins is governed by the four action options in bits C4:C3. ECMP uses the zero flag to generate opposite pin action (synchronized to the loop resolution clock).

angle_comp	Determines if an angle compare is performed. A value of ON causes the comparison to be performed only if the new angle flag is set (NAF = 1). If OFF is specified, the compare is then performed regardless of the state of the new angle flag. Default: OFF.
irq	Specifies whether or not an interrupt is generated. A value of ON sends an interrupt if register and data field values are equivalent. If OFF is selected, no interrupt is generated. Default: OFF.
data	Specifies the value for the data field. This value is compared with the selected register.
hr_data	Specifies the HR delay. Default: 0.

Execution

```
If (Angle Comp. bit == 0 OR (Angle Comp. bit == 1 AND NAF_global == 1))
{

   If (Selected register value == Immediate data field value)
   {

       If (hr_lr bit == 0)
       {
          If (Enable Pin action == 1)
          {
             Selected Pin = Pin Action AT next loop resolution clock + HR delay;
          }
       }
       else
       {
          If (Enable Pin action == 1)
          {
             Selected Pin = Pin Action AT next loop resolution clock;
          }
       }

       If (Z == 1 AND Opposite action == 1)
       {
          If (Enable Pin action == 1)
          {
             Selected Pin = opposite Pin Action AT next loop resolution clock;
          }

          If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
          If ([C28:C27] == 01) Generate request on request line [P25:P23];
          If ([C28:C27] == 11)Generate quiet request on request line [P25:P23];

          If (register R is selected) R register = Compare value (32 bit);
          If (register S is selected) S register = Compare value (32 bit);
          If (register T is selected) T register = Compare value (32 bit);

          Jump to Conditional Address;
       }
   }
   elseIf (Z == 1 AND Opposite action == 1)
   {
      If (Enable Pin action == 1)
      {
         Selected Pin = opposite Pin Action AT next loop resolution clock;
      }
      Jump to Next Program Address;
}
else  // Angle Comp. bit == 1 AND NAF_global == 0
{

Cycles One cycle

Register modified Selected Register (A, B, R, S, T or none)

Description This instruction defines a specialized 25-bit virtual counter used as an event counter or pulse accumulator (see Table 23-85). The counter value is stored in the data field [D31:D7] and the selected register. If one of the 32-bit registers (R,S,T) is selected, the 25 bit count value is stored left justified in the register with zeros in the seven least significant bits.

When an event count condition is specified, the counter value is incremented on a pin edge condition or on the NAF condition (NAF is defined in ACNT). This instruction can be used with all pins.

Copyright © 2018, Texas Instruments Incorporated

event The event that triggers the counter.

Table 23-85. Event Encoding Format for ECNT

Event	C6	C5	C4	Count Conditions	Mode	Int. Available
NAF	0	0	0	NAF flag is Set	Angle counter	Y
FALL	0	0	1	Falling edge on selected pin	Event counter	Y
RISE	0	1	0	Rising edge on selected pin	Event counter	Y
BOTH	0	1	1	Rising and Falling edge on selected pin	Event counter	Y
ACCUHIGH	1	0	-	while pin is high level	Pulse accumulation	N
ACCULOW	1	1	-	while pin is low level	Pulse accumulation	N

irq ON generates an interrupt when event in counter mode occurs. No interrupt is generated with OFF.

Default: OFF.

data 25-bit integer value serving as a counter.

Default: 0.

Execution

```
If (event occurs)
{
   If (Register A or B Selected) {
      Selected register = Immediate Data Field + 1;
   }

   If (Register R, S or T Selected)
   {
      Selected register[31:7] = Immediate Data Field + 1;
      Selected register[6:0] = 0;
   }

   Immediate Data Field = Immediate Data Field + 1;

   If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
   If ([C28:C27] == 01) Generate request on line [P25:P23];
   If ([C28:C27] == 11) Generate quiet request on line [P25:P23];

   Jump to Conditional Address;
}
else
{
    Jump to Next Program Address;
}

Prv bit = Current Logic (Lx) value of selected pin; (Always executed)
```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see Section 23.2.7.

Register modified T (if save sub bit P[5] is set)

Copyright © 2018, Texas Instruments Incorporated

Description

This instruction compares the magnitude of the 25-bit data value stored in the data field (D31-D7) and the 25-bit value stored in the selected ALU register (A, B, R, S, or T).

If the hr_lr bit is reset, pin action will occur after a delay from the next loop resolution clock. If the hr_lr bit is set, the delay is ignored. This delay is programmed in the data field (D6-D0).

When the data value matches, an output pin can be set or reset according to the pin action bit (C[4]). The pin will not change states if the enable pin action bit (C[22]) is reset.

MCMP uses the zero flag set to generate opposite pin action (synchronized to the loop resolution clock). The save sub bit (P[5]) provides the option to save the result of a subtraction into register T.

NOTE: The Difference Between Compare Values

The difference between the two data values must not exceed (2^{24}) - 1.

angle_comp Determines whether or not an angle compare is performed. A value of ON causes the comparison to be performed only if the new angle flag is set (NAF = 1). If OFF is specified, the compare is then performed regardless of the state of the new angle flag.

Default: OFF.

savesub When set, the comparison result is saved into the T register (upper 25 bits).

Default: OFF.

order Specifies the order of the operands for the comparison.

Table 23-86. Magnitude Compare Order for MCMP

Order	C5	Description
REG_GE_DATA	0	Evaluates to true if the register value is greater than or equal to the data field value.
DATA_GE_REG	1	Evaluates to true if the data field value is greater than or equal to the register value.

irq Specifies whether or not an interrupt is generated. A value of ON sends an interrupt if the compare match occurs according to the order selected. If OFF is selected, no interrupt is generated.

data Specifies the value for the data field. This value is compared with the selected register.

hr_data HR delay. The default value for an unspecified bit is 0.

Copyright © 2018, Texas Instruments Incorporated

Execution

```
If (Angle Compare P[7] == 0 OR (P[7] == 1 AND NAF_global == 1))
{
    If(  (Order C[5] == 1) AND (Data[31:7]- Selected register[31:7]) >= 0))
      OR ( (Order C[5] == 0) AND Selected register[31:7] - Data[31:7]) >= 0))
    {
       If (Order C[5] == 1 AND Save subtract P[5] == 1)
       {
          Register T[31:7] = Data[31:7] - Selected register[31:7];
          Register T[6:0] = 0;
       }

       If (Order C[5] == 0 AND Save subtract P[5] == 1)
       {
          Register T[31:7] = Selected register[31:7] - Data[31:7];
          Register T[6:0] = 0;
       }

       If (Enable Pin Action C[22] == 1)
       {
          If (hr_lr P[8] = 0) {
             Schedule Action on Selected Pin C[12:8] at start of next loop
             + HR Delay D[6:0];
          }
          else
          {
             Schedule Pin Action on Selected Pin C[12:8] at start of next loop;
          }
       }

       If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
       If ([C28:C27] == 01) Generate request on request line [P25:P23];

23.6.3.14 MOV32 (Data Move 32)

Syntax

```
MOV32 {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
remote={label | 9-bit unsigned integer}
[control={OFF | ON}]
[z_cond={OFF | ON}]
[init={OFF | ON}]| ON}]
type={IMTOREG | IMTOREG&REM | REGTOREM | REMTOREG}
[reg={A | B | R | S | T | NONE}]
[data={25-bit unsigned integer]
[hr_data={7-bit unsigned integer}]
}
```

Figure 23-153. MOV32 Program Field (P31:P0)

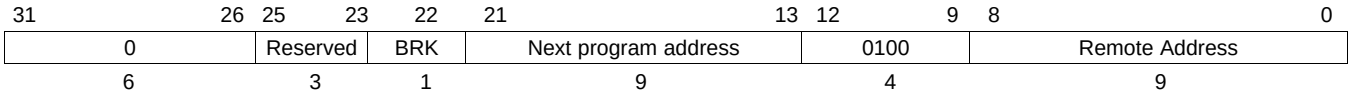

Figure 23-154. MOV32 Control Field (C31:C0)

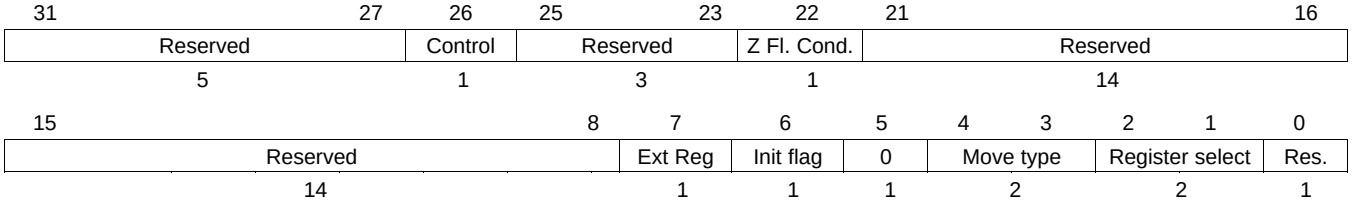

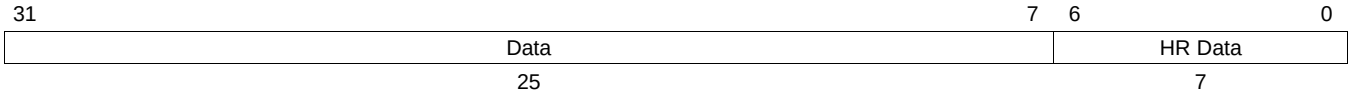

Figure 23-155. MOV32 Data Field (D31:D0)

Cycles One or two cycles

Register modified Selected register (A, B, R, S, or T)

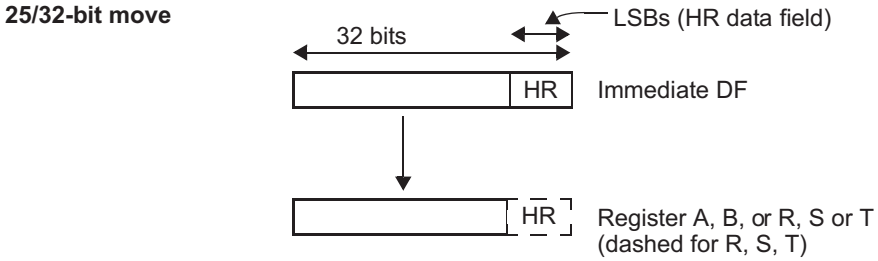
Description MOV32 replaces the selected ALU register and/or the data field values at the remote address location depending on the move type.

Figure 23-156 through Figure 23-159 illustrate these operations. If *no register* is selected, the move is not executed, except for configuration C4:C3 = 01, where the remote data field is written with the immediate data field value.

Copyright © 2018, Texas Instruments Incorporated

remote Determines the location of the remote address.
Default: Current instruction + 1.

z_cond When set to OFF the MOV32 performs the move operation specified by the move type whenever it is executed (independent on the state of the Z-Flag).
When set to ON the MOV32 performs the move operation specified by the move type only when the Z-Flag is set.



init (Optional) Determines whether or not system flags are initialized. A value of ON reinitializes the following system flags to these states:
Acceleration flag (ACF) = 0
Deceleration flag (DCF) = 1
Gap flag (GPF) = 0
New angle flag (NAF) = 0
A value of OFF results in no change to the system flags.

type Specifies the move type to be executed.

Table 23-87. Move Type Encoding Selection

Move Type	C4	C3	Source	Destination(s)	Cycles
IMTOREG	0	0	Immediate data field	Register A, B, R, S, or T	1
IMTOREG&REM	0	1	Immediate data field	Remote data field and register A, B, R, S, or T	1
REGTOREM	1	0	Register A, B, R, S, or T	Remote data field	1
REMTOREG	1	1	Remote data field	Register A, B, R, S, or T	2

Figure 23-156. MOV32 Move Operation for IMTOREG (Case 00)

reg Specifies which register (A, B, T, or NONE) is involved in the move. A register (A, B, or T) must be specified for every move type except IMTOREG&REM. If *NONE* is used with move type IMTOREG&REM, the MOV32 executes a move from the immediate data field to the remote data field. If *NONE* is used with any other move type, no move is executed.

data Specifies a 25-bit integer value to be written to the remote data field or selected register.

hr_data (Optional) HR delay. The default value for an unspecified bit is 0.

Cycles One

Register modified None

Description This instruction modifies the data field and the control field at the remote address.

MOV64 has two distinct syntaxes. In the first syntax, bit values may be set by assigning a value to each of the control fields. This syntax is convenient for modifying control fields that are arranged similarly to the format of the MOV64 control field. A second syntax, in which the entire 29-bit control field is specified by the cntl_val field, is convenient when the remote control field is dissimilar to the MOV64 control field. Either syntax may be used, but you must use one or the either but not a combination of syntaxes. See Figure 23-163.

Register modified Register A

Description This instruction detects the edges of the external signal at loop start and measures its period or pulse duration. The counter value stored in the control field C[24:0] and in the register A is incremented each N2HET loop. PCNT uses the HR structure on the pin to measure an HR period/pulse count value.

hr_lr (Optional) Specifies whether the PCNT instruction captures the HR delay into the HR data field on the selected edge condition. If hr_lr is 0 (HIGH) then PCNT captures the HR delay. if hr_lr is 1 (LOW) then PCNT only captures at loop resolution.

Copyright © 2018, Texas Instruments Incorporated

irq (Optional) Specifies whether or not an interrupt is generated. A value of ON sends an interrupt when a new value is captured. If OFF is selected, no interrupt is generated.

type (Optional) Determines the type of counter that is implemented.

Table 23-90. Counter Type Encoding Format

	P7	P6	Period/Pulse Select	Reset On	Capture On
FALL2RISE	0	0	Count low-pulse duration on selected pin	Falling edge	Rising edge
RISE2FALL	0	1	Count high-pulse duration on selected pin	Rising edge	Falling edge
FALL2FALL	1	0	Count period between falling edges on selected pin	Falling edge	Falling edge
RISE2RISE	1	1	Count period between rising edges on selected pin	Rising edge	Rising edge

period Specifies the 25-bit integer value that holds the counter value. The counter value is also stored in register A.
Default: 0.

data 25-bit integer representing the last captured counter value.
Default: 0.

hr_data HR delay.
Default: 0.

If *period-measure* is selected, PCNT captures the counter value into the period/pulse data field [D31:D7] on the selected edge. The HR structure provides HR capture field [D6:D0]. The counter value [C24:C0] is reset on the same edge. The captured period value is a 32-bit value.

If *pulse-measure* is selected, PCNT captures the counter value into the period/pulse count field [D31:D7] on the selected edge. The HR structure provides HR capture field [D6:D0]. The counter value [C24:C0] is reset on the next opposite edge. The captured pulse value is a 32-bit value.

When the overflow count (all 1's in the counter value) is reached, PCNT stops counting until the next reset edge is detected.

Note: For FALL2FALL/RISE2RISE, the user should always discard the first interrupt/HTU request if interrupt/request are enabled before HET_ON. For both the types, reset edge and capture edge are the same and the interrupt or HTU request is triggered on capture edge (which is nothing but the reset edge). Once the execution unit is enabled, the first edge generates an interrupt but the value of the counter is of no use as this is not the period between 2 edges. So first edge after turning on N2HET is used mainly for resetting the counter and start the period count.

Execution

```
Z = 0;

If (Period C[24:0] != 1FF_FFFFh) {
    Period C[24:0] = Period C[24:0] + 1;
}

Register A = Period C[24:0];

If (specified capture edge detected on selected pin)
{
    Z = 1;

    If (Period value != 1FF_FFFFh)
    {
       HR Capture Value = selected HR counter;
    }
    else
    {
       HR Capture Value = 7Fh;
    }

    If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
    If ([C28:C27] == 01) Generate request on request line [P25:P23];
    If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];
}

If (specified reset edge detected on selected pin)
{
    Period value = 0000000h;
}

Prv bit = Current Logic (Lx) value of selected pin;

Jump to Next Program Address;
```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see Section 23.2.7.

Cycles	One
Register modified	Selected register (A, B or T)
Description	This instruction defines a virtual timer used to generate variable length pulses. The counter value stored in the data field is decremented unconditionally on each timer resolution until it reaches zero, and it then stays at zero until it is reloaded with a non-zero value. The specified pin action is performed as long as the count after count value is decremented is greater than 0. The opposite pin action is performed when the count after decrement just reaches 0. If the hr_lr bit is reset, the opposite pin action will be taken after a HR delay from the next loop resolution clock. If the hr_lr bit is set, the delay is ignored. This delay is programmed in bits [D6:D0].

irq	ON generates an interrupt when the data field value reaches 0. No interrupt is generated for OFF. Default: OFF.
data	25-bit integer value serving as a counter.
hr_data	HR delay. Default: 0.

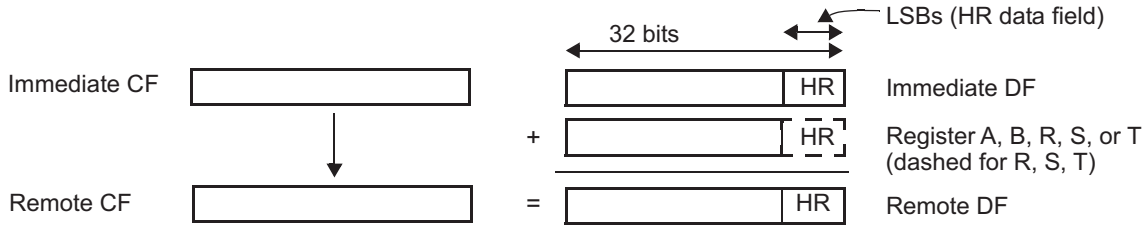
Data	HR Data
25	7



Cycles Normally One Cycle. Two cycles if writing to remote address that is also the next address.

Register modified None

Description This instruction modifies the data field, the HR data field and the control field at the remote address. The advantage over DADM64 is that It executes one cycle faster. In case the R, S, or T register is selected, the addition is a 32-bit addition. The table description shows the bit encoding for determining which ALU register is selected.

RADM64 has two distinct syntaxes. In the first syntax, bit values may be set by assigning a value to each of the control fields. This syntax is convenient for modifying control fields that are arranged similar to the format of the RADM64 control field. A second syntax, in which the entire 29-bit control field is specified by the cntl_val field, is convenient when the remote control field is dissimilar from the RADM64 control field. Either syntax may be used, but you must use one or the either but not a combination of syntaxes. See Figure 23-173.

5	1	1	25

Figure 23-176. RCNT Data Field (D31:D0)

31–7	6–0
Data	Reserved
25	7

Cycles Two Cycles (One Cycle if T=0)

Register modified None

Description RCNT is used with other instructions to convert an input period measurement T_{Input} to the form of (Equation 31) where the input period is expressed as a fraction of a reference period $T_{Reference}$.

$$T_{Input} = T_{Reference} \bullet \left(\frac{N}{M} \right) \quad (31)$$

RCNT computes the numerator N of (Equation 31). The denominator M of (Equation 31) is a constant that is of interest. For example, choosing M = 100 allows the input period to be expressed as a percentage (%) of the reference period. Note that if $T_{Input} > T_{Reference}$, then RCNT will return N > M ; which would be correct if, for example, the input pulse period is 110% of the reference pulse period.

RCNT expects that register T is loaded with the value of $T_{Reference}$. The input period T_{Input} is determined by counting the number of loop resolution periods between edges on the input pin. This information is conveyed through the Z flag from a PCNT instruction that precedes the RCNT instruction.

The divisor field of the RCNT instruction should be chosen as: `Divisor = M · lr` , where M is the desired denominator from (Equation 31) and lr is the loop resolution prescale value.

Copyright © 2018, Texas Instruments Incorporated

An example N2HET program that makes use of the RCNT instruction is:

```
L0: MOV32 { remote=dummy,type=IMTOREG,reg=T,data=0x8,hr_data=0};

L1: PCNT { hr_lr=HIGH,brk=OFF,type=FALL2FALL,pin=0};

L2: RCNT { divisor=320,data=0x4};

L3: BR {cond_addr=L5, event = Z}

L4: ADC { src1=ZERO,src2=IMM,dest=IMM,next=L0,data=0,hr_data=0};

L5: ADD { src1=REM,src2=ZERO,dest=IMM,remote=L4,data=0,hr_data=0};

L6: ADD { src1=ZERO,src2=ZERO,dest=NONE,rdest=REM,
           next=L0,remote=L4,data=0,hr_data=0};

dummy
```

In this small program an input signal on pin 0 is measured both in terms of absolute cycles by the PCNT instruction at L1 and as in 1/10ths of the reference period by the RCNT instruction at L2. In this example the reference period is a constant 0x400 cycles; this value is loaded into register T by the MOV32 instruction at L0. (0x400 is data=8, hr_data=0)

RCNT follows PCNT and is initialized to a working count of T/2 (0x200) whenever the PCNT instruction detects a falling edge on pin 0. Between falling edges on pin0, RCNT accumulates counts 10x faster than PCNT; so that the working data field of RCNT will reach the reference value of 0x400 in 1/10th the time that a PCNT instruction would. Each time the RCNT instruction passes the reference value, it sets the carry out flag and subtracts the reference value from the working count. By accumulating carry-outs from RCNT, the add with carry instruction at L4 effectively counts in increments of 1/10th of the reference period. Note that the divisor value 320 is 10 times 32; this assumes lr=32.

When the next falling edge is detected on pin 0, PCNT sets the Z flag and the RCNT instruction resets again to the initial data field of T/2. RCNT does not modify the Z flag, so that the branch instruction at L3 can execute instructions at L5, L6 instead of L4. The instructions at L5 and L6 capture the final result from L4 and reset the ADC instruction at L4 to zero for the start of the next period measurement.

Execution

```
If (register T[31:0] != 00000000h)
{
   C = 0;

   If (Z == 0)
   {
       Data Field[31:0] = Data Field[31:0] + Divisor[24:0];

       If (Data Field[31:0] >= Reg T[31:0])
       {
          Data Field[31:0]=Data Field[31:0] - Reg T[31:0];
          C = 1;
       }
   }
   else
   {
      Data Field[31:0] = T[31:0] >> 1; /* T/2 */
   }
}

Cycles One

Register modified Register T (implicitly)

Description This instruction alternately performs angle- and time-based operations to generate pulse sequences, using the angle referenced time base. These pulse sequences last for a relative duration using a free running time base. Generally, register B holds the angle values and register A holds the time values. Bit 0 of the conditional address field (C13) specifies whether the instruction is operating in angle or time operation mode.

Copyright © 2018, Texas Instruments Incorporated

When the compared values match in angle mode, a pin can be set or reset according to the pin action bit (C4). The pin does not change states if the enable pin action bit (C22) is reset.

The restart enable bit (C1) provides the option to unconditionally restart a sequence using the X-flag bit of ACMP.

restart	If restart is set to ON and the X flag = 1, the assembler writes a value of 1 into the immediate index field, writes the value in register A into the immediate data field, and jumps to the next program address. The X flag is set or cleared by the ACMP instruction. If restart is set to OFF, the X flag is ignored; no special action is performed. Default: OFF.
irq	ON generates an interrupt if the compare match occurs in angle mode. No interrupt is generated when the field is OFF. Default: OFF.
data	Specifies the 25-bit compare value.
cond_addr	Since the LSB of the conditional address is used to select between time mode and angle mode, and since the conditional address is taken only in time mode, the destination for the conditional address must be odd.

Execution

```
If (Data field value <= Selected register value) Cout = 0; else Cout = 1;

If (Restart Enable == 1 AND X == 1)
{
   C13 = 1;
   Immediate Data Field = Register A;
   Cout = 0;
   Jump to Next Program Address;
}

If (Angle Mode (C13 == 0) AND ((Restart En. == 1 AND X == 0) OR Restart En. == 0))
{
   If (Z == 0 AND (Register B value - Angle Inc. < Data field value) AND Cout == 0) OR
      (Z == 1 AND (Cout_prv == 1 OR Cout == 0)))
   {
      If (Enable Pin Action == 1) Selected Pin = Pin Action;
      If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
      If ([C28:C27] == 01) Generate request on request line [P25:P23];
      If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];

      Immediate Data Field = Register A;
      C13 = 1; /*** switch to Time Mode ***/

   }
   Jump to Next Program Address;
}
Else If (Time Mode (C13 == 1)) AND ((Restart En. == 1 AND X == 0) OR Restart En. == 0)
{
   /* Result of subtract must not exceed 2^24 - 1 */
   Register T = Register A - Immediate Data Field;
   Jump to Conditional Program Address;
}
Cout_prv = Cout; (always executed)
```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see Section 23.2.7.

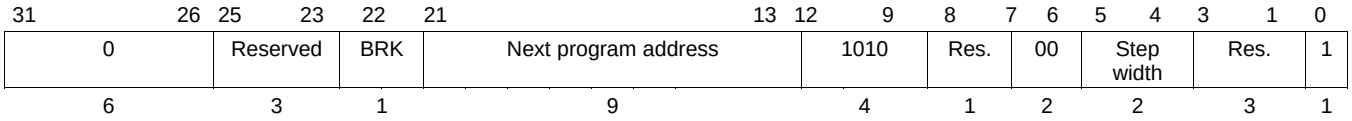
23.6.3.21 SCNT (Step Count)

Syntax

```
SCNT {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
step={8 | 16 | 32 | 64}
[control={OFF | ON}]
gapstart={25-bit unsigned integer}
[data={25-bit unsigned integer]
}
```

Figure 23-180. SCNT Program Field (P31:P0)



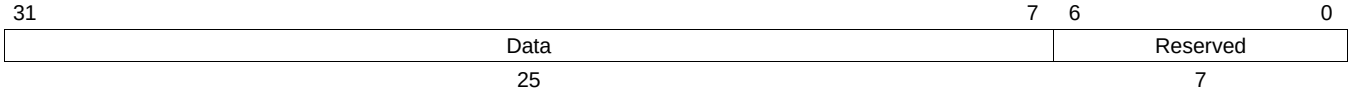


Figure 23-181. SCNT Control Field (C31:C0)

Figure 23-182. SCNT Data Field (D31:D0)

Cycles One or two cycles (two cycles when DF is involved in the calculations)

Register modified Register A

Description This instruction can be used only once in a program and defines a specialized virtual timer used after APCNT and before ACNT to generate an angle-referenced time base synchronized to an external signal (that is, a toothed wheel signal) as defined in APCNT and ACNT. Step width selection bits are saved in two flags, SWF0, and SWF1, to be re-used in ACNT.

SCNT multiplies the frequency of the external signal by a constant *K* defined in the step width field, [P5:P4]. The bit encoding for this field is defined in Table 23-93.

step Specifies the step increment to be added to the counter value each program resolution. These two bits provide the values for the SWF0 and SWF1 flags. The valid values are listed in Table 23-93.

Copyright © 2018, Texas Instruments Incorporated

Table 23-93. Step Width Encoding for SCNT

P5	P4	Step Width (K)
0	0	8
0	1	16
1	0	32
1	1	64

gapstart Defines the gap start angle, which SCNT writes to register A. The gap start value has no effect on the SCNT instruction, but if the ACNT instruction is being used, register A must contain the correct gap start value. For a typical toothed wheel gear:

GAPSTART = (*stepwidth* × (*actual teeth on gear* - 1)) + 1.

data Specifies the 25-bit integer value serving as a counter.

Default: 0.

This instruction is incremented by the step value K on each timer resolution up to the previous period value P(n-1) measured by APCNT (stored in register T). The resulting period of SCNT is: P(n - 1)/K

Due to stepping, the final count of SCNT will not usually exactly match the target p(n-1). SCNT compensates for this error by starting each cycle with the remainder of the previous cycle.

When SCNT reaches the target p(n-1), the zero flag is set as an increment condition for ACNT.SCNT also specifies a gap start angle, defining the start of a range in ACNT where period measurements in APCNT are temporarily stopped to mask singularities in the external signal.

SCNT uses register A to store the gap start value. Gap start has no effect for SCNT.

Execution

```
SWF1 = P5;
SWF0 = P4;
Z = 0;

If (register T != 0000000h)
{
   If (DCF == 1 OR ACF == 1)
   {
      Data Field register = 0000000h;
      Counter value = 0000000h;
   }

   If (DCF == 0 AND ACF == 0)
   {
      Data Field register = Data field register + Step Width;
   }

   If ((Data Field register - register T) >= 0)
   {
      Data field register = Data Field register - register T;
      Z = 1;
   }

   Register A = Gap start value;

}

Jump to Next Program Address;

23.6.3.23 WCAP (Software Capture Word)

Syntax

```
WCAP {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[reqnum={3-bit unsigned integer}
[request={NOREQ | GENREQ | QUIET}]
[hr_lr={HIGH | LOW}]
[control={OFF | ON}]
[prv={OFF | ON}]
[cond_addr={label | 9-bit unsigned integer}]
pin ={pin number}
event={NOCOND | FALL | RISE | BOTH}
reg={A | B | R | S | T | NONE}
[irq={OFF | ON}]
[data={25-bit unsigned integer]
[hr_data={7-bit unsigned integer}]
}
```

Figure 23-186. WCAP Program Field (P31:P0)

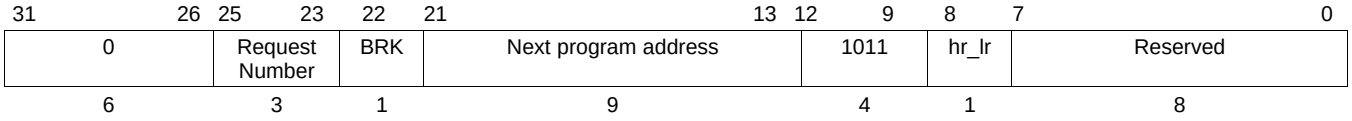

Figure 23-187. WCAP Control Field (C31:C0)

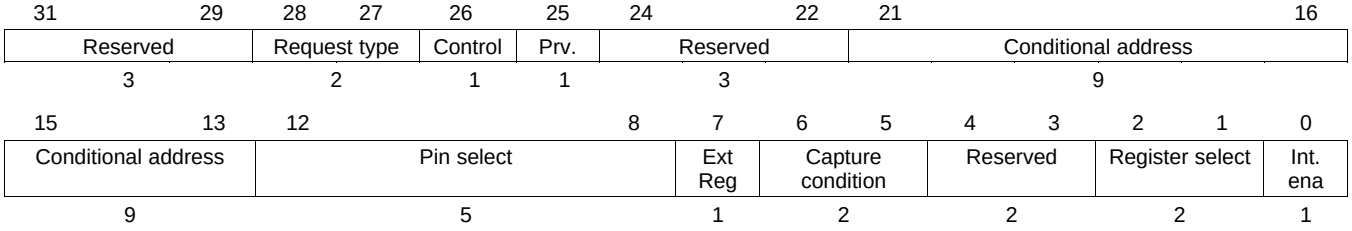

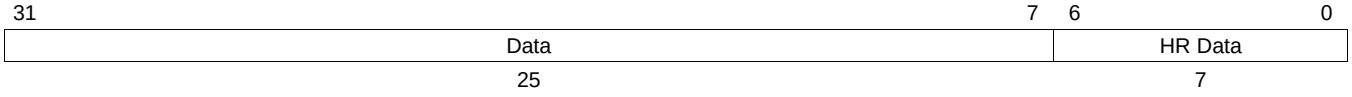

Figure 23-188. WCAP Data Field (D31:D0)

Cycles One

Register modified None

Description This instruction captures the selected register into the data field if the specified capture condition is true on the selected pin. This instruction can be used with all pins.

If the hr_lr bit is reset, the WCAP instruction will capture an HR time stamp into the data field on the selected edge condition. If the hr_lr bit is set, the HR capture is ignored.

Copyright © 2018, Texas Instruments Incorporated

event Specifies the event that triggers the capture.

Table 23-96. Event Encoding Format for WCAP

C6	C5	Capture Condition
0	0	Always
0	1	Capture on falling edge
1	0	Capture on rising edge
1	1	Capture on rising and falling edge

irq ON generates an interrupt when the capture condition is met. No interrupt is generated for OFF.
Default: OFF.

data Specifies the 25-bit integer value to be written to the data field or selected register.

hr_data HR capture value.
Default: 0.

NOTE: WCAP in HR Mode: The HR Counter starts on a WCAP instruction execution (in the first loop clock) and will synchronize to the next loop clock. When N2HET is turned on and a capture edge occurs in the first loop clock (where the HR counter hasn't been synchronized to the loop clock), then the captured HR counter value is wrong and is of no use. So the captured HR data in the first loop clock should be ignored.

Execution

```
If (Specified Capture Condition is true on Selected Pin
OR Unconditional capture is selected)
{
   Immediate Data Field = Selected register value;

   If (hr_lr bit == 0) Capture the HR value in Immediate HR Data Field;

   If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
   If ([C28:C27] == 01) Generate request on request line [P25:P23];
   If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];

   Jump to Conditional Address;
}

Jump to Next Program Address;

Prv bit = Current Logic (Lx) value of selected pin; (always executed)
```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see Section 23.2.7.

High-End Timer Transfer Unit (HTU) Module

This chapter describes the high-end timer transfer unit (HTU) module. The HTU is similar to the DMA (Direct Memory Access) module, but it is specialized to transfer N2HET (High-End Timer) data to or from the microcontroller RAM.

NOTE: This chapter describes a superset implementation of the HTU module that includes features and functionality that require DMA. Since not all devices have DMA capability, consult your device-specific datasheet to determine applicability of these features and functions to your device being used.

Topic **Page**

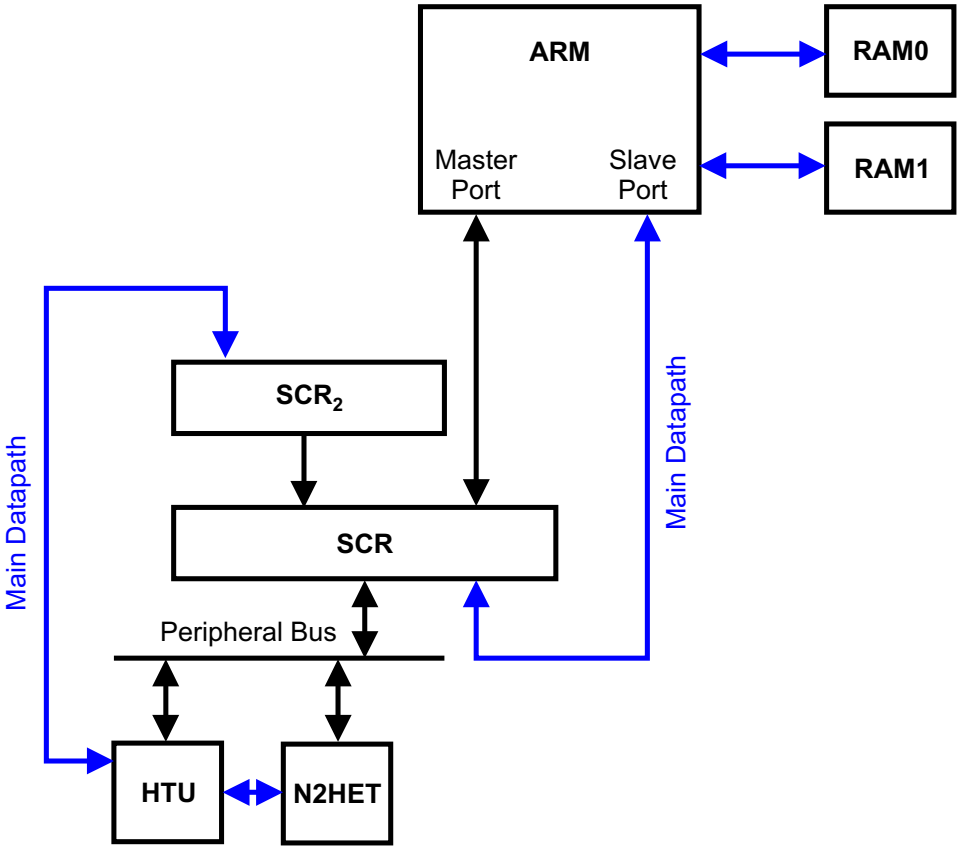
24.1 Overview

The HET transfer unit is a dedicated direct memory access controller that transfers data between the N2HET RAM and RAM buffers located in the main memory address range. This eliminates time consuming CPU accesses to the N2HET RAM to gather measurement data or creating output waveforms and thus freeing up the CPU to perform other tasks.

24.1.1 Features

- Independently transfers data between the N2HET and the main memory
- 8 double control packets supporting dual buffer configuration
- Transfer requests generated by N2HET instructions/events
- One shot, circular and auto switch buffer transfer modes for each double control packet for flexible buffer handling
- Constant and post-increment addressing modes
- 32- or 64-bit transactions
- Programmable memory protection region
- Parity protect control packet RAM
- Extensive diagnostic functionality



Copyright © 2018, Texas Instruments Incorporated

24.2 Module Operation

The HTU is tightly coupled to the N2HET and is not intended to transfer data from other peripheral modules. It initiates transfers with the help of requests generated by the N2HET program and configurable control packets. Figure 24-1 shows a system block diagram of the HTU and the main path for the data transfer. The tight coupling and the dedicated bus into the SCR (Switched Central Resource) reduces the amount of data transferred on the peripheral bus, which increases the overall system performance. However if the application decides to use the direct CPU access method to the N2HET RAM, it is free to do so.

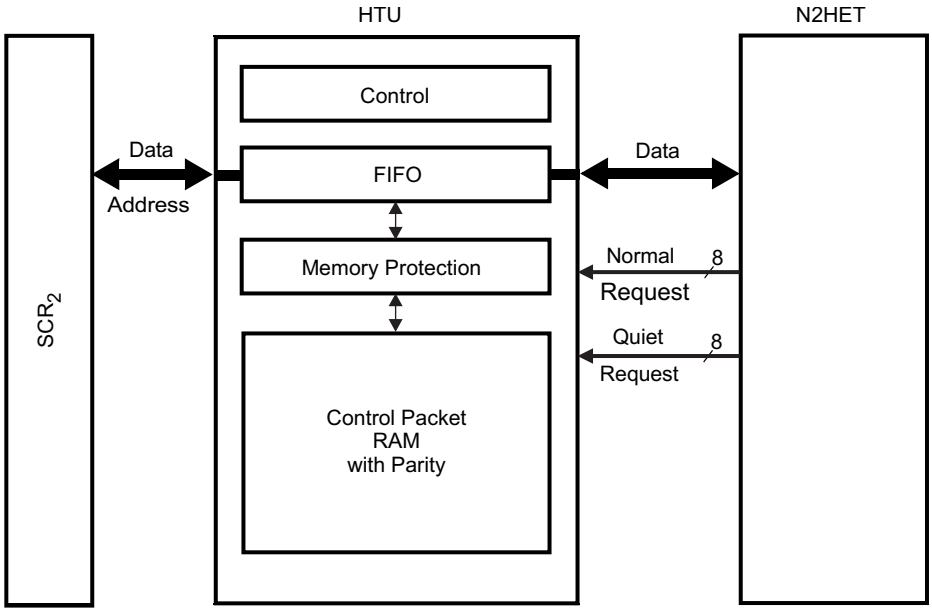


Figure 24-2 shows a more detailed block diagram of the HTU module.

Figure 24-1. System Block Diagram

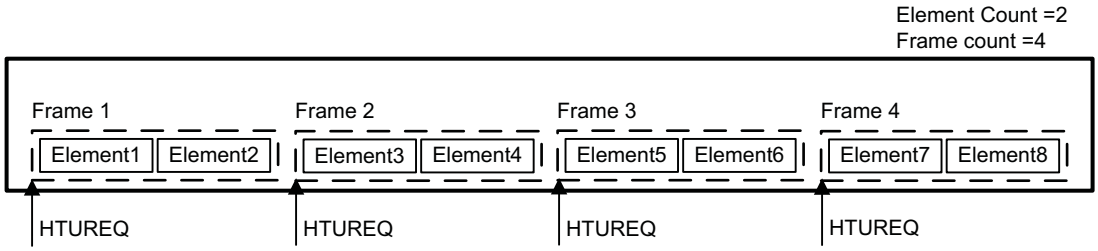
Figure 24-2. HTU Block Diagram

Transfers between N2HET RAM and the main memory are triggered by 8 different normal N2HET requests. Quiet requests are used for specific cases and are discussed in Section 24.2.4.1. Control packets, which store the source and destination addresses, the transfer count and other information (see Section 24.5), are associated with the requests. A FIFO decouples the read- and write-path and allows to do data-packing in the case of different read- and write-data sizes. The application can specify a section of memory into or from which the data is transferred. This serves as memory protection in the case that information in the control packet RAM was unintentionally altered and avoids that the HTU can overwrite important application data.



Control packets are implemented as double control packets (DCP) which allow to specify two buffers for the data transfer. This enables the CPU to work with one buffer, while new data is transferred to/from the other buffer.

The control packet defines:

- the start address of the source/destination buffers
- the N2HET instruction address location
- how many elements need to be transferred per request
- the buffer size as the number of elements times the number of frames
- the buffer handling

A transfer is triggered when a certain condition (for example, capture, compare condition) is detected by a N2HET instruction. The N2HET instruction specifies which request line to the HTU will be triggered at the event. The DCPs have a fixed assignment to the request lines and the corresponding assignment can be found in the device datasheet. Once a request is triggered, it starts a frame transfer. A frame can contain one or more elements. Elements are defined as 32-bit or 64-bit words of data.

24.2.1 Data Transfers between Main RAM and N2HET RAM

24.2.1.1 Addressing Modes

The addressing modes of a control packet need to be distinguished between the main RAM of the CPU and the N2HET RAM.

Main RAM

For each double control packet (see Section 24.2.1.3), the addressing mode for the main RAM (RAM0/1) can be configured to constant or post-increment mode in register IHADDRCT.

- **Constant Addressing:** In constant mode, the HTU writes/reads the data to/from the same address in the main RAM.
- **Post-increment Addressing:** In post-increment mode, the HTU writes/reads the data to/from the main RAM by incrementing through the addresses after each transfer. If 32-bit transfers are selected it will automatically increment by 4 Byte, if 64-bit transfers are selected, it will increment by 8 Byte. The examples of Use Cases illustrate the post-increment mode, where the elements of consecutive frames are transferred to/from consecutive locations in the main RAM buffer.

N2HET RAM

How a DCP addresses the N2HET RAM is determined by the initial N2HET address, the initial element counter (IETCOUNT) and the N2HET addressing mode (ADDMH). The main difference to the main RAM addressing mode is that the HET address is reset to the initial HET address for every first element of a frame. To implement constant addressing, the initial element counter needs to be set to 1. Post-increment addressing is selected by programming the initial element counter to a value other than 1.

24.2.1.2 Single Buffer Implementation

In a single buffer implementation, the DCP is set up to transfer data to/from a single buffer in the main RAM. With each transfer request, the programmed number of elements is transferred and the buffer pointer is reset to its starting address after the programmed number of frame transfers have completed.

Figure 24-4 shows the request on one request line of the HTU and the frame running on the assigned control packet visualized by the element counter. In the diagram, the frame has 5 element transfers (element count = 5).

Before the application reads the buffer, it has to disable the control packet to avoid that new data overwrites the buffer while it's being accessed by the application. Regardless of the control packet being disabled at t1 or t2 the last frame will always be completed, since the trigger request has been received already. The application can determine any ongoing transfers by the TIPF flag and the NACP bits.

- **One Shot Buffer Mode:** If TMBA or TMBB is set to one shot buffer mode then the data stream will stop after all elements of buffer A or buffer B have been transferred. This means that the corresponding DCP will be disabled after the last frame was transferred to/from buffer A or B and CFTCTA or CFTCTB decrements to 0.
- **Circular Buffer Mode:** If TMBA or TMBB is set to circular buffer mode, then the data stream will continue back at the start of buffer A or B after all elements of buffer A or B have been transferred. The example of Timing Example for Circular Buffer Mode assumes IETCOUNT = 3 (Initial Element Transfer Count), IFTCOUNT = 3 (Initial Frame Transfer Count, SIZE = 0 (Size of Transfer = 32-bit) and ADDFM = 0 (Addressing Mode Main Memory = Post Increment). So there are in total 9 32-bit values in the buffer. It also assumes IFADDRx = 10h. "U" means uninitialized.

24.2.1.3 Dual Buffer Implementation

The transfer unit provides **double control packets (DCPs)** supporting the use of two buffers per data stream (per HTU request source). If one buffer should be read by the CPU or DMA, the data stream is directed to the other buffer and the first buffer is frozen. Switching to the other buffer can be triggered with a write access to the CPENA register or with the DCP configured to automatically switch to the other buffer when the programmed number of frames has been transmitted. Freezing the buffer avoids this buffer to be overwritten with new HET data while the CPU or DMA reads this buffer.

Figure 24-6 shows a timing example of two HET instructions 1 and 2, which are the request sources for the HTU (and are controlled by DCP 1 and DCP 2). Each generated frame has 5 element transfers. Request source 1 has two RAM buffers, controlled by two control packets 1A and 1B. Request source 2 has two RAM buffers, controlled by two control packets 2A and 2B.

Figure 24-6. Dual Buffer Timing

Copyright © 2018, Texas Instruments Incorporated

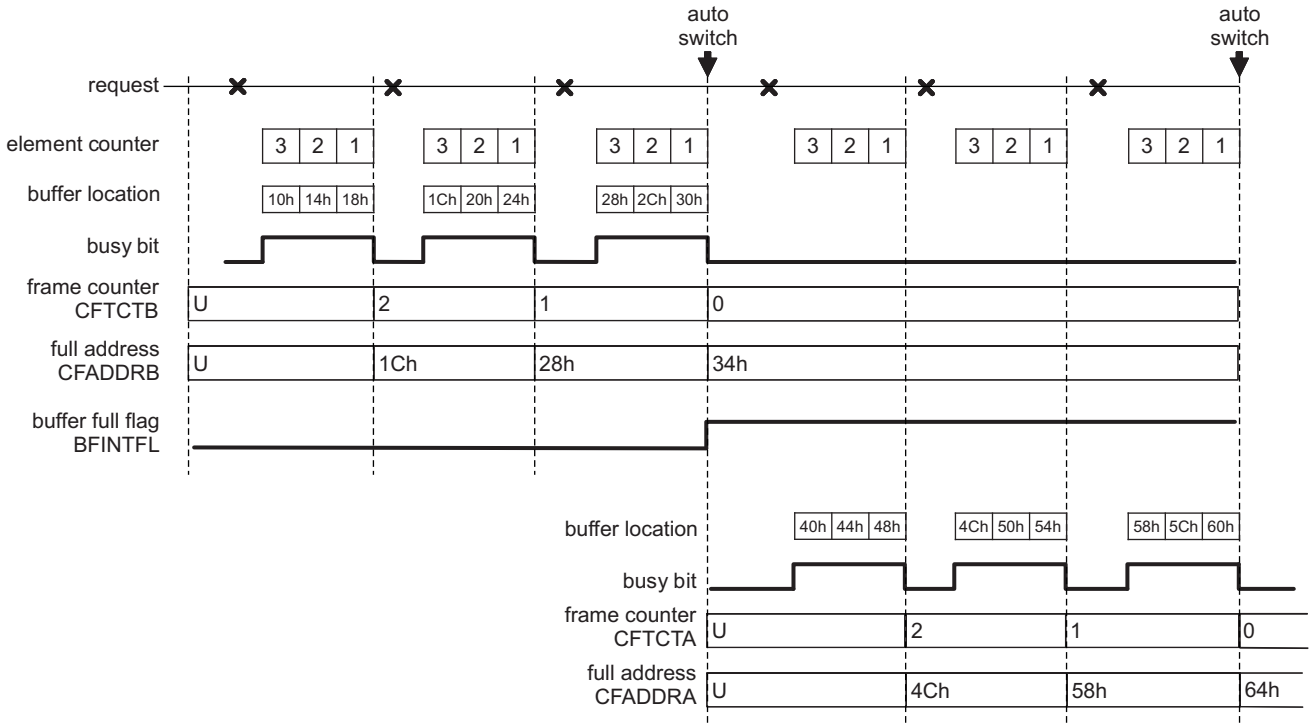

Figure 24-6 shows a switch at time t1, where buffer 1A is frozen and data stream 1 is directed to buffer 1B, but only after the frame has been completed. It also shows the time (t2 or t3) where 2A is frozen and data stream 2 is directed to buffer 2B. If the switch happens between the request and the start of the frame (for example, time t3), then the frame is processed by the new control packet (although the old control packet was active at the time of the request). The delays between the HTU requests and the start of the element transfers result from the fact that the HTU can process only one transfer at a time.

Auto Switch Buffer Mode

If TMBA is set to auto switch mode, then the data stream will continue at the start of buffer B after all elements of buffer A have been transferred. This means that in the CPENA register, CP A is disabled and CP B is enabled automatically and buffer B uses its initial main memory address and initial frame counter to start. The same principle is valid for TMBB and buffer B.

The examples of Figure 24-7 assumes IETCOUNT=3 (Initial Element Transfer Count), IFTCOUNT=3 (Initial Frame Transfer Count, SIZE=0 (Size of Transfer = 32-bit) and ADDFM=0 (Addressing Mode Main Memory = Post Increment). So there are in total 9 32-bit values in buffer A and B. It also assumes IFADDRB=10h and IFADDRA=40h. "U" means uninitialized.

Figure 24-7. Timing Example for Auto Switch Buffer Mode

Copyright © 2018, Texas Instruments Incorporated

24.2.1.4 General Control Packet Behavior

The action defined by the selected mode will be performed at the end of the last frame, which has the frame counter value of 1. The one shot and auto switch mode will automatically update the CPENA register at this time. Note, that for all three modes listed above, it is possible to switch to the other buffer by writing to CPENA before the end of the current buffer is reached.

If a write access to CPENA happens while the last frame of DCP x (with frame counter = 1) is transferred then the priority is defined by Table 24-1.

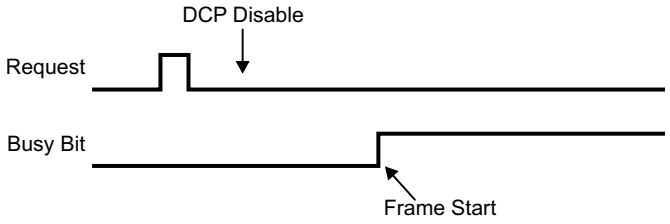

Table 24-1. CPENA / TMBx Priority Rules

Write access to CPENA bits (2 × x+1) and (2 × x) during the frame with frame counter = 1 [1]	Priority Rule
Disable: 01 --> 00 or 10 --> 00	Disabling the DCP by the write to CPENA has priority, TMBx is ignored.
Stay: 01 --> 01 or 10 --> 10	The write access to CPENA is ignored, TMBx has priority and defines the action.
Switch: 01 --> 10 or 10 --> 01	Switching the DCP by the write to CPENA has priority, TMBx is ignored.

(1) See read table of CPENA register (Table 24-14)

There could be a case where the CPU wants to do main memory operations, but does not want the HTU modifying the main memory. It could happen that a request was already active, but the frame transfer hasn't started yet when the application disabled the control packets. The timing diagram in Figure 24-8 shows this scenario.

Figure 24-8. Timing for Disabling Control Packets

Since the request for the transfer was already received before the DCPx is disabled, the HTU will still start the frame transfer. The application would poll the BUSYx bit during the time the DCPx was disabled and before the frame was started and would read a non-busy information. It then would start the main memory operations thinking all transfers have completed, however after some time the HTU will start the outstanding frame transfer and corrupt the main memory.

To avoid this, the application can set the VBUSHOLD bit to disable all transactions between the HTU and the main memory. It has to poll the BUSBUSY bit to ensure that no outstanding transactions on the bus are pending. The HTU will still receive all transfer requests from the N2HET, but it will not be able to transfer any data to or from the main memory, while the VBUSHOLD bit is set.

24.2.2 Arbitration of HTU Elements and Frames

- Frames do not interrupt each other. If a request occurs on DCP x while another frame runs on DCP y (and x ≠ y), then the current frame completes before the new frame starts.
- If two or more request lines are active, the request line with the lower number (specified in the request number field of the corresponding N2HET instruction) is serviced first.

Copyright © 2018, Texas Instruments Incorporated

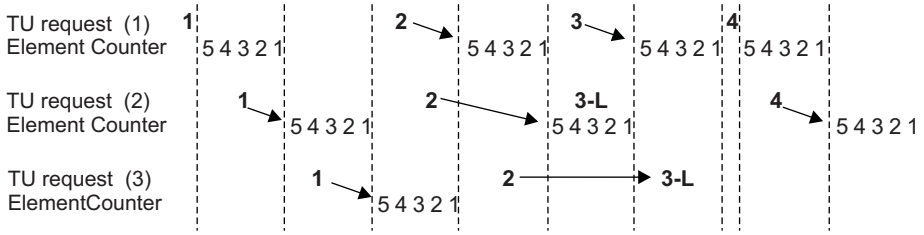
24.2.3 Conditions for Frame Transfer Interruption

If a frame is currently transferred on DCP x and one of the events listed below happens, then the event will (1.) clear the element counter of DCP x, (2.) stop new element transfers on DCP x (3.) clear the active busy bit of DCP x and (4.) disable DCP x in the CPENA register. The DCPs other than DCP x will not be affected.

- Request Lost Error of DCP x (with CORL bit set to 0).
- Parity Error of DCP x (with parity check enabled and COPE bit set to 0). See also Section 24.2.6.
- Bus Error of DCP x.
- Memory Protection Error of DCP x (with memory protection enabled). See also Section 24.2.5.
- Writing a 1 to a BUSY bit (belonging to DCP x) if that bit is 1. There is no effect if the BUSY bit is 0.
- Writing a 1 to the HTURES bit.

When a memory protection error occurs, the access to the protected address is blocked. The frame is stopped before the element, which caused the violation transfer, starts. All other errors will let the current element transfer finish.

In case of the Request Lost and Bus Error, one more element transfer goes on the bus, before the frame is actually stopped. Accordingly, the busy bit is cleared after the element, which follows the element that caused the error.



In case of the Bus Error, the counter for the element, which follows the element that caused the error, is captured to the ERRETC register field.

NOTE: If the HTUEN bit is cleared during a frame is transferred, then the frame will be completed before the HTU is disabled.

24.2.4 HTU Overload and Request Lost Detection

If the number of different HTU request sources is "high", the period between the requests is "short" and/or the initial element counter values are "big", then the HTU could get into a overload situation. In Figure 24-9, all requests marked with "L" are lost, since their frame is not completed at the time the next request occurs. Each number in the rows "TU request (x)" represents a time, where the associated N2HET instruction generates a request on DCP x. The arrows in Figure 24-9 point to the associated frame, which could be delayed compared to the request. The delays are caused by different frames, which are currently processed. The figure assumes that the CORL bit in the RLBECTRL register is set, which causes the DCP to stay enabled and let the data stream continue after a request lost error occurred on the DCP (see 3-L for TU request (2)).

Figure 24-9. Timing Example Including Lost Requests

Lost requests are signaled with the RLOSTFL register, and if enabled, can generate request lost interrupts.

If the CORL bit is set, a frame will be completed and the corresponding DCP stays enabled even if a request lost was generated during this frame.

In dual buffer mode, the request lost detection works continuously, independent of the CP switches.

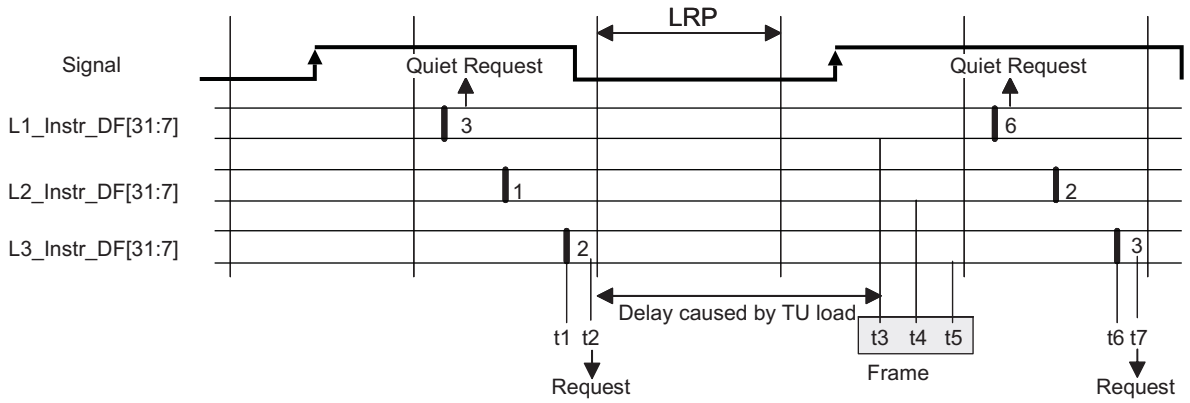
Copyright © 2018, Texas Instruments Incorporated

24.2.4.1 Requests and Quiet Requests

In addition to generating too many transfer requests and thus overloading the HTU and not being able to transfer data at all, it can happen that inconsistent data is transferred. The following examples illustrate such scenarios.

In the examples below, the HTU reads a frame of three elements from the datafield of three different instructions. In Figure 24-10, the L3-Instruction generates the HTU request at time t2, t7, and so on. and the according frame (at t3). The frame is delayed because of the HTU load. However, as shown in Figure 24-10, the delay still allows the frame to complete before the datafield of instruction L1 is updated again. However, when the delay is longer (as shown in Figure 24-11), then the frame could fall into the N2HET loop (LRP), in which the N2HET updates the data fields of the L1, L2 and L3 instructions. In this case, the HTU could read inconsistent data as shown in the diagram. A wrong (new) value is read from L1 (at time t3), but correct ("old") values are read from L2 and L3 (at times t4 and t5).

Figure 24-10. Timing that Generates No Request Lost Error



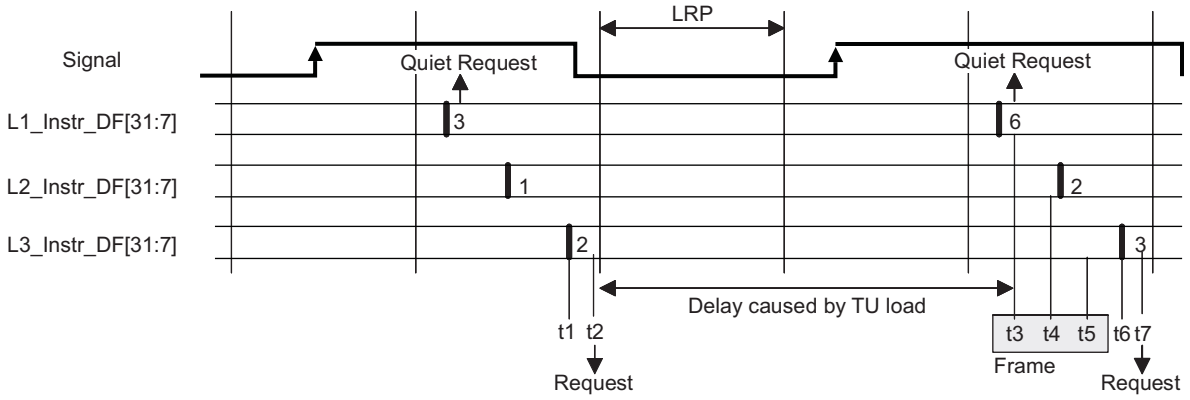


Figure 24-11. Timing that Generates a Request Lost Error

To prevent sending inconsistent data, the N2HET instructions are able to generate a **quiet request**, which does not originate a transfer but is only used by the HTU for consistency check. If a frame has not completed since the last request (or has not even started) at the time the quiet request occurs, then the HTU signals a request lost error. All instructions, which allow to generate a request can be configured to generate a quiet request instead. So in the examples of Figure 24-10 and Figure 24-11, instruction L1 should be configured to generate a quiet request and instruction L3 to generate a normal request. In the case of Figure 24-11, the corresponding bit in the RLOSTFL register will be set.

It is the responsibility of the N2HET software to enable a quiet request for the first instruction of an instruction block, which is addressed by DCP x, and to enable a normal request only for the last instruction of this block. Since enabling the quiet request should enable a proper request lost detection for DCP x, both N2HET instructions need to specify the same DCP x (reqnum=x).

Copyright © 2018, Texas Instruments Incorporated

The control fields of the HET instructions provide a 2-bit field to configure one of the following possibilities (as shown in Table 24-2). A 3-bit field in the program field will select which of the 8 Double Control Packets will be triggered by the request.

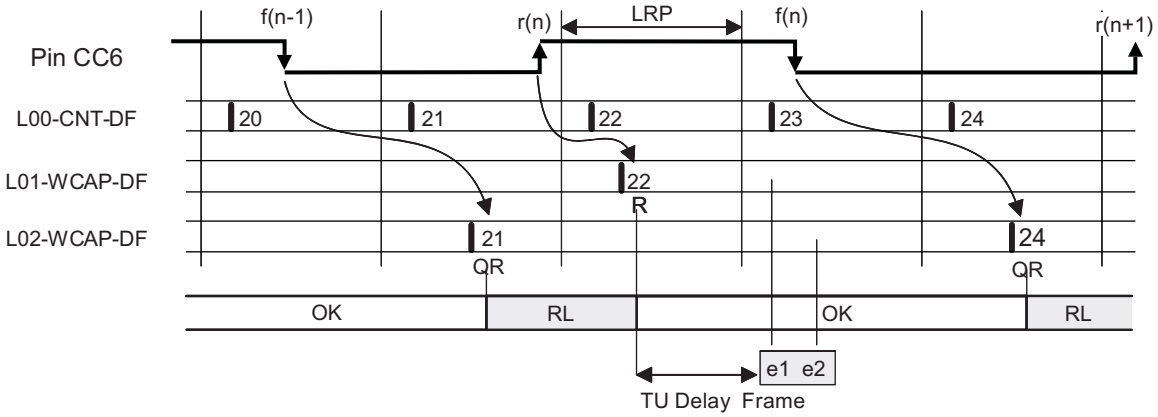

Table 24-2. Triggered Control Packets

Request Type Bit 1	Request Type Bit 0		Request Number
Don't care	0	No request	Specify number 0, 1,... or 7, which selects the HTU or DMA request line.
0	1	Generate normal request	
1	1	Generate quiet request	

In the case of very light HTU load, but higher signal requirements (for example, high frequency), the quiet request could also be used to define periods in which the data read by a control packet is safe. The following HET code will capture counter time stamps to the L1-WCAP data field after rising edges (at pin CC6) and to the L2-WCAP data field after falling edges (at pin CC6):

```
L0 CNT  {reg=A, max=0x1FFFFFF}
L1 WCAP {reqnum=3, request=GENREQ, event=RISE, reg=A, pin=CC6}
L2 WCAP {reqnum=3, request=QUIET, event=FALL, reg=A, pin=CC7}
; HET HRSHARE feature configured to assign both WCAPs to pin CC6
```

Figure 24-12. Timing Example for Two WCAP Instructions

The HTU frame will have two elements: The first gives the time stamp of the rising edge r(n) and the second gives the time stamp of the previous falling edge f(n-1). Using the code above, requests (R) and the quiet requests (QR) will occur at the times shown in Figure 24-12, and a request lost will only be signaled when the frame makes an access during the times marked with RL. So reading [22, 21] as frame elements is correct. If the signal frequency would increase, then a wrong pair [22, 23] could be read, but this will be signaled by a request lost error since at least e2 falls into the RL period.

Copyright © 2018, Texas Instruments Incorporated

24.2.5 Memory Protection

This feature allows restricting accesses to certain areas in memory in order to protect critical application data from unintentionally being manipulated by the HTU.

If the HTU memory protection feature is disabled, the full 4 GB address range can be accessed by the HTU without exception. There are two memory regions that start and end addresses can be configured.

With the HTU memory protection feature enabled, read and write accesses by the HTU IFADDRA and IFADDRB registers inside the defined regions are allowed. HTU access to its tightly-coupled memory is independent of the MPU, it routes through the dedicated HTU/N2HET bus using the IHADDR bits in the IHADDRCT register. See Section 24.2 for details on the tightly-coupled bus. For accesses outside the regions, one of two modes is configurable:

- Any access performed by the HTU is forbidden and will be signaled to the ESM module. Write accesses will be blocked.
- Read access is allowed but write access will be blocked and signaled to the ESM module.

To use one region only, REG01ENA must be 0. Bits ACCR01, INTENA01, and register settings of MP1S and MP1E will be ignored.

To use both regions, the following rules must be followed:

1. Memory mapped region 0 covers a lower memory area as Memory mapped region 1.
2. REG01ENA is a 1 and REG0ENA is a 0.
3. ACCR01 is set for the desired access type, ACCR0 is ignored.
4. INTENA01 is set for the desired action, INTENA0 is ignored.

If an element transfer of DCP x generates a memory protection error, then:

1. The element counter of DCP x is cleared.
2. All new element transfers on DCP x are stopped.
3. The active busy bit of DCP x is cleared.
4. DCP x is disabled in the CPENA register. The DCPs other than DCP x will not be affected.
5. The FT flag will be set.
6. An error is signaled to the ESM module.

24.2.6 Control Packet RAM Parity Checking

The HTU module can detect parity errors in the DCP (Double Control Packet) RAM. DCP RAM parity checking is implemented using one parity bit per byte. Even or odd parity checking can be selected in the DEVCR1 register of the system module and can be enabled/disabled by a 4-bit key in the PCR register.

During a read access to the DCP RAM, the parity is calculated based on the data read from the RAM and compared with the good parity value stored in the parity bits. The parity check is performed when the HTU or any other master (for example, CPU) makes a read access to the DCP RAM. A read access within the RAM section of an initial or current DCP checks all 16 bytes of the DCP at a time (see also DCP memory map). For example, if a byte read access happens for DCP RAM address 0, but there is a parity error at byte address Ch then the parity error will occur and the captured parity address will be Ch and not 0. The address of the byte in which the error occurred can be read from the PAR register. If successive DCP RAM read accesses generate multiple parity errors, only the address of the first detected error will be captured and the PAR register will not be updated by subsequent errors until it is read by the application. When multiple errors in a 16 byte word are detected, only the address of the lowest byte will be captured.

The application can decide whether to stop any transfers when a parity error is detected or to continue transferring data. If the COPE (Continue On Parity Error) bit is 0 and parity checking is enabled, then the HTU will not start the frame and the corresponding DCP will be automatically disabled in the CPENA register. If a master other than the HTU (for example, CPU) reads the RAM section of DCP x and a parity error is detected during this read access, while the parity check is enabled and the COPE bit is 0, then the DCP x will be automatically disabled in the CPENA register. If a frame for this DCP x is ongoing during

Copyright © 2018, Texas Instruments Incorporated

this read access, then in addition the element counter of DCP x is cleared, all new element transfers on DCP x are stopped and the active busy bit of DCP x is cleared. With COPE set to 1 and the parity check enabled, the parity checking will still be performed, but the data transfer of an active DCP continues after a parity error was detected for this DCP. So neither the DCP with the parity error will be disabled nor the frame will be stopped.

After a DCP is enabled (with CPENA using BIM=0), then at the start of the first frame, the HTU performs the parity check only on the initial DCP, since it does not need the current DCP information. For further frames, the HTU performs the parity check for both initial and current DCP, since it needs both information.

On a parity error detection, an error will also be signaled to the ESM module.

24.2.6.1 Parity Bit Mapping and Testing

To test the parity checking mechanism, the parity RAM can be made accessible in order to allow manual fault insertion. Once the TEST bit is set, the parity bits are mapped to address FF4E 0200h.

When in test mode (the parity RAM is accessible), no parity checking will be done when reading from parity RAM, but parity checking will still be performed for read accesses to the DCP RAM.

Table 24-3 and Table 24-4 show how the corresponding parity bits of the DCP RAM bytes are mapped into the memory.

Table 24-3. DCP RAM

Bit	31 24	23 16	15 8	7 0
FF4E 0000h	Byte 0	Byte 1	Byte 2	Byte 3
FF4E 0004h	Byte 4	Byte 5	Byte 6	Byte 7
FF4E 0008h	Byte 8	Byte 9	Byte 10	Byte 11
FF4E 000Ch	Byte 12	Byte 13	Byte 14	Byte 15

Table 24-4. DCP Parity RAM

Bit	24		16		8		0
FF4E 0200h		P0		P1		P2		P3
FF4E 0204h		P4		P5		P6		P7
FF4E 0208h		P8		P9		P10		P11
FF4E 020Ch		P12		P13		P14		P15

Each byte in DCP RAM has its own parity bit in the DCP Parity RAM. P0 is the parity bit for byte 0, P1 is the parity bit for byte 1, and so on.

24.2.6.2 Initializing Parity Bits

After device power up, the DCP RAM content including the parity bit cannot be guaranteed. In order to avoid parity failures, when reading DCP RAM, the RAM has to be initialized first. This can simply be done by writing known values into the RAM by software and the corresponding parity bit will be automatically calculated.

Another possibility to initialize the DCP memory and its parity bits is to use the system module, which is an on-chip module external to the HTU. This module can start the automatic initialization of all RAMs on the microcontroller including the HTU DCP RAM. This function initializes the complete DCP RAM to 0 when activated by the system module. Depending on the even/odd parity selection, all parity bits will be calculated accordingly. The HTUEN bit must be cleared and the parity functionality must be enabled (by PARITY_ENA) during the automatic DCP RAM initialization. If HTUEN is 1 when the initialization is triggered by the system module, then the initialization will not be performed and the HTU operation is not affected. If a 1 is written to HTUEN during the initialization, then the HTUEN bit will be set but the HTU will not be enabled before the initialization completes.

24.3 Use Cases

24.3.1 Example: Single Element Transfer with One Trigger Request

This example considers the case that the HTU fills a RAM buffer in the main (CPU) data RAM. The HTU reads from the instruction which generates the HTU requests.

This example uses a PCNT instruction. Every time the PCNT has captured a new pulse or period value, it will automatically generate a transfer request to the HTU, which then transfers the value from the N2HET RAM to the buffer RAM. So over time consecutive locations in the RAM buffer can be filled with consecutive measurement values captured into the N2HET RAM data field of the same PCNT instruction without loading or interrupting the CPU.

24.3.2 Example: Multiple Element Transfer with One Trigger Request

The following example shows how the HTU could be used to fill a RAM buffer with a data stream including different types of measurement values belonging to the same N2HET input signal (on one pin): Time stamp values (WCAP), edge counter values (ECNT) and last period values (PCNT).

Figure 24-13 shows the timing and Table 24-5 shows the byte addresses of the program- (PF), control- (CF), data- (DF) and reserved field (res) of the WCAP-ECNT-PCNT instruction block. The timing and code example assumes that all three instructions are assigned to the same N2HET pin.

Figure 24-13. Timing of the WCAP, ECNT, PCNT Example

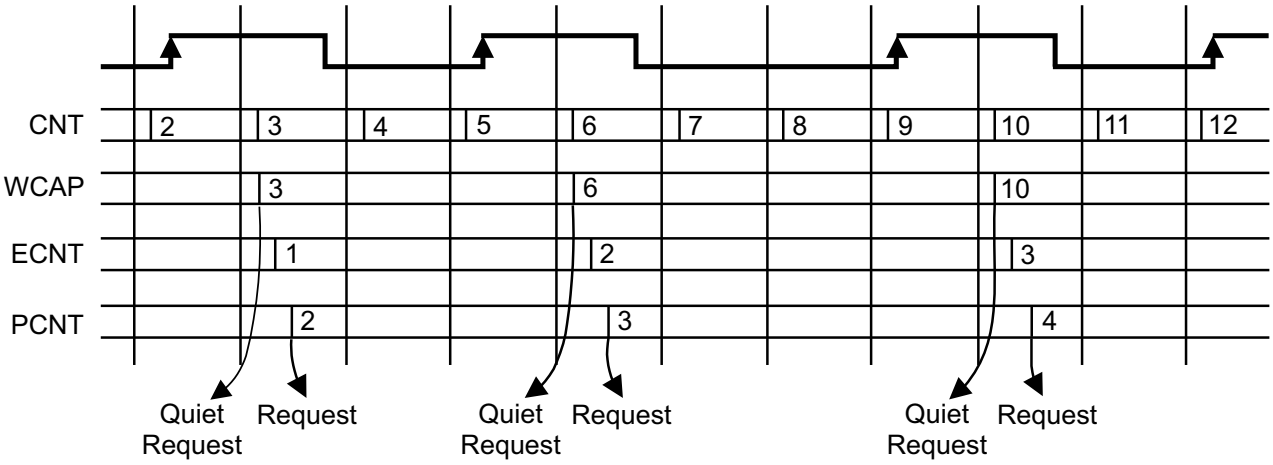

Table 24-5. Field Addresses of the WCAP, ECNT, PCNT Example

	PF	CF	DF	Res
WCAP	30h	34h	38h	3Ch
ECNT	40h	44h	48h	4Ch
PCNT	50h	54h	58h	5Ch

In the HET code the HTU request is enabled only for the last instruction (PCNT) of the WCAP-ECNT-PCNT block. When the PCNT condition is true, it will cause the generated HTU frame to perform three HTU element reads from the data fields of WCAP, ECNT, and PCNT.

Copyright © 2018, Texas Instruments Incorporated

32-Bit-Transfer of data fields:

Table 24-6 shows how the internal element counter, frame counter and the address registers change over time for the example described above. Every time the PCNT instruction captures a new value it generates a request to the HTU, which starts a frame. At the end of each frame the frame counter decrements.

Table 24-6. 32-Bit-Transfer of Data Fields(1)

Frame Counter	3			2			1		
Element Counter	3	2	1	3	2	1	3	2	1
Source Address (HET)	38h	48h	58h	38h	48h	58h	38h	48h	58h
Destination Address (main CPU RAM)	70h	74h	78h	7Ch	80h	84h	88h	8Ch	90h

(1) Shows the byte addresses

The destination buffer is filled with the WCAP, ECNT, and PCNT data field values as shown in Table 24-7.

Table 24-7. Destination Buffer Values

Address	Frame Count	Instruction	Value
70h	3	WCAP	3
74h	3	ECNT	1
78h	3	PCNT	2
7Ch	2	WCAP	6
80h	2	ECNT	2
84h	2	PCNT	3
88h	1	WCAP	10
8Ch	1	ECNT	3
90h	1	PCNT	4

The corresponding setup of the HTU control packet for this example is as follows:

```
IHADDR    = 0x38                // points to WCAP data field
IFADDRA   = 0x70                // points to buffer
ITCOUNT [frame count = 3] [element count = 3]
IHADDRCT = [DIR: Read HET and write to full address]
           [SIZE: 32 bit]
           [ADDMH: Increment HET address by 16 bytes]
           [ADDMF: Post increment full address mode]
           [Any transfer mode]
```

Copyright © 2018, Texas Instruments Incorporated

24.3.3 Example: 64-Bit-Transfer of Control Field and Data Fields

Table 24-8 shows how the internal element counter, frame counter and the address registers change over time assuming the same example as in Section 24.3.2, but now with a transfer size set to 64-bit. The HET address now points to the control field of the instruction, so CF and DF are transferred as 64 bit data.

Table 24-8. 64-Bit-Transfer of Control Field and Data Fields(1)

Frame Counter	3			2			1		
Element Counter	3	2	1	3	2	1	3	2	1
HET (Source) Address	34h	44h	54h	34h	44h	54h	34h	44h	54h
Full (Destination) Address	70h	78h	80h	88h	90h	98h	A0h	A8h	B0h

(1) Shows the byte addresses.

The destination buffer is filled with the WCAP, ECNT, and PCNT control and data field values as shown on the right in Table 24-9.

Table 24-9. Destination Buffer Values

Address	Frame Count	Instruction	Value
70h	3	WCAP	Control Field Value
74h	3	WCAP	3
78h	3	ECNT	Control Field Value
7Ch	3	ECNT	1
80h	3	PCNT	Control Field Value
84h	3	PCNT	2
88h	2	WCAP	Control Field Value
8Ch	2	WCAP	6
90h	2	ECNT	Control Field Value
94h	2	ECNT	2
98h	2	PCNT	Control Field Value
9Ch	2	PCNT	3
A0h	1	WCAP	Control Field Value
A4h	1	WCAP	10
A8h	1	ECNT	Control Field Value
ACh	1	ECNT	3
B0h	1	PCNT	Control Field Value
B4h	1	PCNT	4

The necessary setup of the HTU control packet (see Section 24.5) for this example is as follows:

```
IHADDR   = 0x34  (points to WCAP control field)
IFADDR   = 0x70  (points to buffer)
ITCOUNT [frame count = 3] [element count = 3]
IHADDRCT = [DIR: Read HET and write to full address]
           [SIZE: 64 bit]
           [ADDMH: Increment HET address by 16 bytes]
           [ADDMF: post increment full address mode]
           [Any transfer mode]
```

For different applications, which have the transfer direction set for reading the buffer and writing to HET fields, the 64-bit transfer could be used to change the conditional addresses together with a new data field.

24.4 HTU Control Registers

Table 24-10 provides a summary of the registers. The registers support 8-bit, 16-bit, and 32-bit writes. The offset is relative to the associated peripheral select. See the following sections for detailed descriptions of the registers. The base address for the control registers is FFF7 A400h for HTU1 and FFF7 A500h for HTU2. The address locations not listed, are reserved.

Table 24-10. HTU Control Registers

Offset	Acronym	Register Description	Section
00h	HTU GC	Global Control Register	Section 24.4.1

24.4.1 Global Control Register (HTU GC)

Figure 24-14. Global Control Register (HTU GC) [offset = 00]

31	25	24	23	17	16
Reserved		VBUSHOLD	Reserved		HTUEN
R-0		R/WP-0	R-0		R/WP-0

15	9	8	7	1	0
Reserved		DEBM	Reserved		HTURES
R-0		R/WP-0	R-0		R/WP-0

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 24-11. Global Control Register (HTU GC) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	VBUSHOLD		Hold the VBUS bus
		0	The VBUS is not held.
		1	The VBUSHOLD bit holds the bus used to transfer data between the HTU and the N2HET module. When the BUS_BUSY bit is 0 then the bus is no longer busy. While the bus is held, requests will still be accepted. They will be acted upon when the VBUSHOLD is 0. Request lost conditions will be detected and interrupts generated if they are enabled.
23-17	Reserved	0	Reads return 0. Writes have no effect.
16	HTUEN		Transfer Unit Enable Bit
		0	The Transfer Unit is disabled.
		1	The Transfer Unit is enabled.
			The configuration registers and control packets should be set up first before the HTUEN bit is set to 1 to prevent it from carrying out unintended bus transactions. If the HTUEN bit is cleared to 0 during a frame is transferred, then the frame will be completed before the HTU is disabled.
			The HTUEN bit must be cleared to 0 and the parity functionality must be enabled (by PARITY_ENA) during the automatic DCP RAM initialization (see Initializing Parity Bits). If HTUEN is 1 when the initialization is triggered by the system module, then the initialization will not be performed and the HTU operation is not affected. If a 1 is written to HTUEN during the initialization, then the HTUEN bit will be set but the HTU will not be enabled before the initialization completes.
			Note: If HTU is disabled during a frame transfer, then the ongoing current frame will be completed before the HTU module is disabled. If enabled again, then the transfer will restart from the initial frame count for the CP programmed.
15-9	Reserved	0	Reads return 0. Writes have no effect.
8	DEBM		Debug Mode
		0	The Transfer Unit is stopped in debug mode.
			The HTU will complete the current frame, but not start any new frames. It will also ignore all requests from the HET and not generate any request lost signals.
		1	The Transfer Unit continues operation in debug mode.
			Note: Since the HET has also an "ignore suspend" bit, there a several possibilities for the behavior of the HET and HTU in suspend mode.
7-1	Reserved	0	Reads return 0. Writes have no effect.
0	HTURES		HTU Software Reset Request
		0	Reset request is not issued to the HTU module. Writing a 0 has no effect.
		1	Reset request is issued to the HTU module.
			Ongoing element transfers will be completed, before resetting the complete HTU module, similar to a hardware reset. The HTURES bit will also be cleared. The recommended order of operations is: • Set the software reset bit. This also clears HTUEN. • Wait for the HTURES bit to clear. • Configure the HTU registers and packets. • Set the HTUEN bit to begin operation.

24.4.2 Control Packet Enable Register (HTU CPENA)

This register enables or disables the individual double control packets (DCP).

Figure 24-15. Control Packet Enable Register (HTU CPENA) [offset = 04h]

31															16
Reserved															
R-0															
15															0
CPENA															
R/WP-0															

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 24-12. Control Packet Enable Register (HTU CPENA) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0. Writes have no effect.
15-0	CPENA		CP Enable Bits Bits (2*x) and (2*x+1) of CPENA control the double control packet (DCP) x (whereby x must be within 0,1,....,7). See Table 24-13 for write rules. See Table 24-14 for read rules.

Table 24-13. CPENA Write Results

Bit (2*x+1)	Bit (2*x)	Control packets (CP) B and A of DCP x are affected as follows:
0	0	CP B and A are not changed.
0	1	CP B is disabled and CP A are enabled simultaneously.
1	0	CP B is enabled and CP A are disabled simultaneously.
1	1	CP B and CP A are both disabled simultaneously.

Table 24-14. CPENA Read Results

Bit (2*x+1)	Bit (2*x)	State of DCP:
0	0	The DCP is disabled.
0	1	CP B is disabled and CP A is enabled.
1	0	CP B is enabled and CP A is disabled.
1	1	Cannot be read.

- The conditions listed in Section 24.2.3 can automatically disable DCP x. In this case, bits (2*x) and (2*x+1) are both automatically set to 0.
- When bits (2*x) and (2*x+1) change from 00 to 01 or from 00 to 10 caused by a write access to CPENA, then old pending requests on the corresponding request line are cleared. This means only new requests which occur **after** this write access cause the first HTU transfer for this DCP. This is **not** the case when **switching** CPs (from 10 to 01 or from 01 to 10).
- CP A and/or CP B of a DCP can be configured to one-shot, circular or auto-switch transfer mode via the TMBA or TMBB bits in the IHADDRCT control packet configuration. If a write access to CPENA occurs during the last frame of a buffer (with frame counter = 1) then the action defined by the write access to CPENA and the action defined by TMBx can contradict. The priority rules for this case are given in Table 24-1.

24.4.3 Control Packet (CP) Busy Register 0 (HTU BUSY0)

This register displays the status of individual control packets.

Figure 24-16. Control Packet (CP) Busy Register 0 (HTU BUSY0) [offset = 08h]

31	25	24	23	17	16
Reserved		BUSY0A	Reserved		BUSY0B
R-0		R/W1CP-0	R-0		R/W1CP-0

15	9	8	7	1	0
Reserved		BUSY1A	Reserved		BUSY1B
R-0		R/W1CP-0	R-0		R/W1CP-0

LEGEND: R/W = Read/Write; R = Read only; W1CP = Write 1 in privilege mode only to clear the bit; -*n* = value after reset

Table 24-15. Control Packet (CP) Busy Register 0 (HTU BUSY0) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	BUSY0A		Busy Flag for CP A of DCP 0
23-17	Reserved	0	Reads return 0. Writes have no effect.
16	BUSY0B		Busy Flag for CP B of DCP 0
15-9	Reserved	0	Reads return 0. Writes have no effect.
8	BUSY1A		Busy Flag for CP A of DCP 1
7-1	Reserved	0	Reads return 0. Writes have no effect.
0	BUSY1B		Busy Flag for CP B of DCP 1

The bit is **set** when the frame on the according control packet **starts** (as shown in the diagram below, there could be a delay between the request and the start of the frame).

The bit is automatically **cleared** at any of the following conditions:

1. At the end of a frame.
2. Writing a 1 to a BUSY bit (of DCP x) if that bit is 1. This will:
   a. clear the element counter of DCP x
   b. stop all new element transfers on DCP x
   c. clear the busy bit
   d. and disable DCP x in the CPENA register.

   There is no effect, if the BUSY bit is 0.
3. At the conditions listed in Section 24.2.3.

A write access to the CPENA register can stop a control packet (CP) in single buffer mode or it can switch to the other CP of a DCP in dual buffer mode. If stopping or switching occurs while a frame runs on the currently active control packet, the CPU can poll the busy bit to determine when it is safe to read the buffer.

Table 24-19. Active Control Packet and Error Register (HTU ACPE) Field Descriptions

Bit	Field	Value	Description
31	ERRF		Error Flag
		0	No error occurred.
		1	This bit is set when one of the conditions listed at ERRETC is fulfilled and ERRETC and ERRCPN are captured. Once ERRF is set, it is cleared when reading the upper 16-bit word of the ACPE register or the complete 32-bit register. It is also cleared when writing a 1 to ERRF. ERRF can be used to indicate if ERRETC and ERRCPN contain new unread data.
30-29	Reserved	0	Reads return 0. Writes have no effect.

Copyright © 2018, Texas Instruments Incorporated

Table 24-19. Active Control Packet and Error Register (HTU ACPE) Field Descriptions (continued)

Bit	Field	Value	Description
28-24	ERRETC		Error Element Transfer Count If one of the following conditions happens the current element transfer counter of the control packet (specified by ERRCPN) is captured to ERRETC. Please see Section 24.2.3. • Request Lost Error of control packet specified by ERRCPN. This is independent of the CORL bit. • Parity Error of control packet specified by ERRCPN. This requires the parity check to be enabled, but is independent of the COPE bit. • Bus Error of control packet specified by ERRCPN. • Memory Protection Error of control packet specified by ERRCPN. This requires the memory protection to be enabled. • Writing a 1 to a BUSY bit, which belongs to the control packet specified by ERRCPN, if that bit is 1. There is no effect, if the BUSY bit is 0. ERRETC is frozen from being updated until the upper 16-bit word of the ACPE register or the complete 32-bit register is read by the CPU. After this read, the HTU will update ERRETC if one of the above conditions is fulfilled again. During debugging, ERRETC stays frozen even when reading the upper 16-bit word or the 32-bit register.
23-20	Reserved	0	Reads return 0. Writes have no effect.
19-16	ERRCPN		Error Control Packet Number If one of the conditions listed at ERRETC happens the number of the control packet, which caused the condition, is captured to ERRCPN. **Control Packet** — **ERRCPN Value** CP A of DCP x — 2 x CP B of DCP x — 2 x+1 With x = 0,1,...or 7 ERRCPN is frozen from being updated until the upper 16-bit word of the ACPE register or the complete 32-bit register is read by the CPU. After this read, the HTU will update ERRCPN if one of the above conditions is fulfilled again. During debugging, ERRCPN stays frozen even when reading the upper 16-bit word or the 32-bit register. If one of the conditions is fulfilled, ERRETC and ERRCPN are updated simultaneously.
15	TIPF		Transfer in Progress Flag
		0	No transfers are in progress.
		1	A transfer is currently active. This bit is the result of a logical OR function of all BUSYxx flags of the 4 BUSYx registers.
14	BUSBUSY		Bus is Busy
		0	Bus between N2HET and HTU is not busy.
		1	When BUSBUSY is 1, the bus is busy with a transfer. It is different from TIPF above because BUSBUSY will go low after VBUSHOLD is set to 1 and no transfers are pending between the HTU and the main memory. TIPF will remain 1, if a transfer is still pending and VBUSPHOLD is 1.
13	Reserved	0	Reads return 0. Writes have no effect.
12-8	CETCOUNT		Current Element Transfer Count CETCOUNT shows the current element transfer counter for the frame that is currently processed. If the HTU does not currently transfer any frame, CETCOUNT is 0. CETCOUNT is updated after the write part of a transfer. There is a period of up to 7 cycles between the time the CETCOUNT is 0 and the HTU is finished updating the current DCP (and the CPENA registers, if the required conditions are fulfilled).
7-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	NACP		Number of Active Control Packet Indicates which CP currently processes a frame. **Active or Recent DCP** — **NACP Value** CP A of DCP x — 2 x CP B of DCP x — 2 x+1 With x = 0,1,...or 7 NACP is updated at the time the frame starts on the according CP, and it is updated with a new value when a frame starts on a different CP. Note, that there can be a delay between the request and the start of the frame.

R-0		R/WP-0	R-0		R/WP-0

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 24-20. Request Lost and Bus Error Control Register (HTU RLBECTRL) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reads return 0. Writes have no effect.
16	BERINTENA		Bus Error Interrupt Enable Bit
		0	The bus error interrupt is disabled for all DCPs.
		1	The bus error interrupt is enabled for all DCPs.
15-9	Reserved	0	Reads return 0. Writes have no effect.
8	CORL		Continue On Request Lost Error
		0	Stop current frame on request lost detection. Please see Section 24.2.3.
		1	If CORL is 1 and DCP x is enabled, then DCP x will stay enabled after a request lost condition on DCP x and element transfers will continue.
7-1	Reserved	0	Reads return 0. Writes have no effect.
0	RLINTENA		Request Lost Interrupt Enable Bit
		0	The request lost interrupt is disabled for all DCPs. Disabling RLINTENA will not clear the flags in the RLOSTFL register.
		1	The request lost interrupt is enabled for all DCPs. If bits are set in the RLOSTFL flag register at the time RLINTENA is (re-) enabled, then the according interrupt(s) will occur (in the order of the priority of the request lines).

Table 24-21. Buffer Full Interrupt Enable Set Register (HTU BFINTS) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0. Writes have no effect.
15-0	BFINTENA		Bus Full Interrupt Enable Bits. If the interrupt for CP A of a DCP is enabled, then the interrupt is generated once buffer A is full, that is, once the frame counter CFTCTA decrements to 0. The same applies for CP B (and CFTCTB).
		0	Interrupt is disabled. Writing a 0 has no effect.
		1	Writing to bit (2*x) enables the interrupt for CP A of DCP x.
			Writing to bit (2*x+1) enables the interrupt for CP B of DCP x.

24.4.10 Buffer Full Interrupt Enable Clear Register (HTU BFINTC)

This registers allows to disable the buffer full interrupts for the different control packets. Reading registers BFINTS and BFINTC will return the same bits indicating the status which interrupt is enabled (1) or disabled (0)

24.4.11 Interrupt Mapping Register (HTU INTMAP)

Figure 24-24. Interrupt Mapping Register (HTU INTMAP) [offset = 2Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 24-23. Interrupt Mapping Register (HTU INTMAP) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reads return 0. Writes have no effect.
16	MAPSEL		Interrupt Mapping Select Bit
		0	If MAPSEL is 0, then one bit of CPINTMAP selects one of two interrupt priorities 0 or 1 for the **buffer full** interrupt for the according CP. The **request lost** and **bus error** interrupts of all CPs are set to priority 0, independent of CPINTMAP.
		1	If MAPSEL is 1, then one bit of CPINTMAP determines if the **buffer full**, **request lost** and **bus error** interrupts of the according CP are assigned either to interrupt line 0 or to 1.
15-0	CPINTMAP		CP Interrupt Mapping Bits
		0	Interrupt of CP A (bit 2-x) of DCP x is mapped to interrupt line 0. Interrupt of CP B (bit 2*x+1) of DCP x is mapped to interrupt line 0.
		1	Interrupt of CP A (bit 2-x) of DCP x is mapped to interrupt line 1. Interrupt of CP B (bit 2*x+1) of DCP x is mapped to interrupt line 1.

24.4.12 Interrupt Offset Register 0 (HTU INTOFF0)

The INTOFF0 register reflects the highest priority interrupt flag bit set in the BERINTFL, RLOSTFL, or BFINTFL flag registers with the appropriate CPINTMAP bit set to 0. The priority order (from high to low) is: BER, RLOST, buffer-full. Interrupts for request lines with lower number have higher priority.

Figure 24-25. Interrupt Offset Register 0 (HTU INTOFF0) [offset = 34h]

31	16

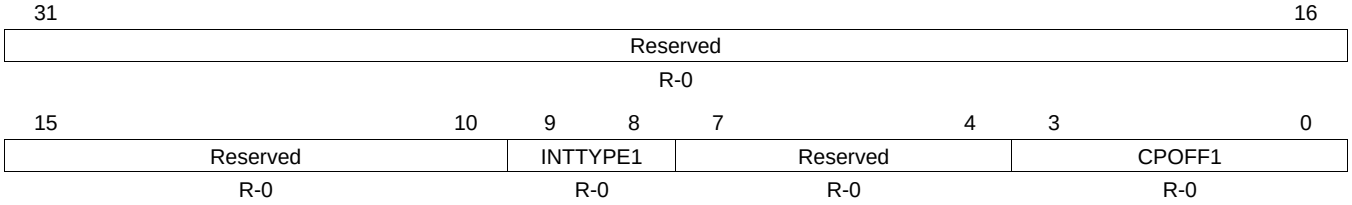
Table 24-24. Interrupt Offset Register 0 (HTU INTOFF0) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads return 0. Writes have no effect.
9-8	INTTYPE0		Interrupt Type of Interrupt Line 0. Indicates whether a buffer-full, RLOST, or BER interrupt, assigned to interrupt line 0, is currently pending.
		0	No interrupt.
		1h	Interrupt caused by full buffer on CP/DCP specified by CPOFF0.
		2h	RLOST interrupt generated by CP/DCP specified by CPOFF0.
		3h	BER interrupt generated by CP/DCP specified by bits CPOFF0.
7-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	CPOFF0		CP Offset. Indicates for which control packet the interrupt is pending, which is classified by INTTYPE0 and is assigned to interrupt line 0.
		0	DCP 0, CP A
		1h	DCP 0, CP B
		2h	DCP 1, CP A
		3h	DCP 1, CP B
		4h	DCP 2, CP A
		5h	DCP 2, CP B
		6h	DCP 3, CP A
		7h	DCP 3, CP B
		8h	DCP 4, CP A
		9h	DCP 4, CP B
		Ah	DCP 5, CP A
		Bh	DCP 5, CP B
		Ch	DCP 6, CP A
		Dh	DCP 6, CP B
		Eh	DCP 7, CP A
		Fh	DCP 7, CP B

NOTE: Reading CPOFF0 will clear the bit generating the current interrupt from appropriate flag register (BERINTFL, RLOSTFL, or BFINTFL), except when in debug mode where reading CPOFF0 will have no effect on the flag registers.



In order to read INTTYPE0 and CPOFF0 simultaneously, always read this register using word or half-word but not using byte accesses.

Copyright © 2018, Texas Instruments Incorporated

24.4.13 Interrupt Offset Register 1 (HTU INTOFF1)

This register is organized identically to the INTOFF0 register. The difference is that INTOFF1 reflects the highest priority interrupt flag bit set in the BERINTFL, RLOSTFL, or BFINTFL flag registers with the appropriate CPINTMAP bit set to 1.

Figure 24-26. Interrupt Offset Register 1 (HTU INTOFF1) [offset = 38h]

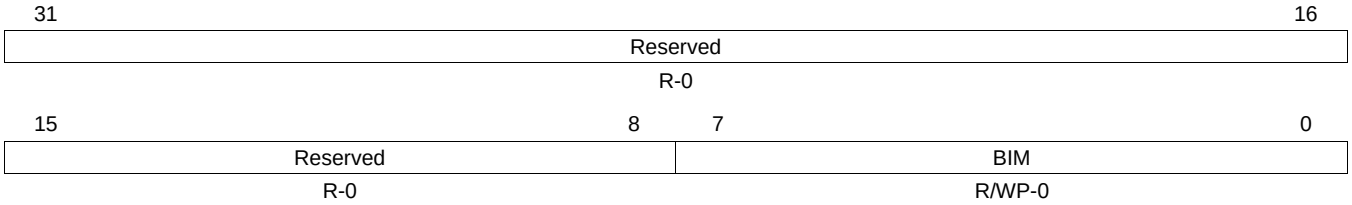
LEGEND: R = Read only; -*n* = value after reset

Table 24-25. Interrupt Offset Register 1 (HTU INTOFF1) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads return 0. Writes have no effect.
9-8	INTTYPE1		Interrupt Type of Interrupt Line 1. Indicates whether a buffer-full, RLOST, or BER interrupt, assigned to interrupt line 1, is currently pending.
		0	No interrupt.
		1h	Interrupt caused by full buffer on CP/DCP specified by CPOFF1.
		2h	RLOST interrupt generated by CP/DCP specified by CPOFF1.
		3h	BER interrupt generated by CP/DCP specified by bits CPOFF1.
7-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	CPOFF1		CP Offset. Indicates for which DCP / CP the interrupt is pending, which is classified by INTTYPE1 and is assigned to interrupt line 1.
		0	DCP 0, CP A
		1h	DCP 0, CP B
		2h	DCP 1, CP A
		3h	DCP 1, CP B
		4h	DCP 2, CP A
		5h	DCP 2, CP B
		6h	DCP 3, CP A
		7h	DCP 3, CP B
		8h	DCP 4, CP A
		9h	DCP 4, CP B
		Ah	DCP 5, CP A
		Bh	DCP 5, CP B
		Ch	DCP 6, CP A
		Dh	DCP 6, CP B
		Eh	DCP 7, CP A
		Fh	DCP 7, CP B

NOTE: Reading CPOFF1 will clear the bit generating the current interrupt from appropriate flag register (BERINTFL, RLOSTFL, or BFINTFL), except when in debug mode where reading CPOFF1 will have no effect on the flag registers.

In order to read INTTYPE1 and CPOFF1 simultaneously, always read this register using word or half-word but not using byte accesses.



Copyright © 2018, Texas Instruments Incorporated

24.4.14 Buffer Initialization Mode Register (HTU BIM)

This register enables special applications, where one CP is temporarily disabled, but after having re-enabled the CP, filling the buffer should not start back at its beginning, but should continue after the last element of the previous run.

Table 24-27 shows more details on the BIM usage.

Figure 24-27. Buffer Initialization Mode Register (HTU BIM) [offset = 3Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 24-26. Buffer Initialization Mode Register (HTU BIM) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	BIM		Buffer Initialization Mode The BIM bits and the TMBx bits determine when a buffer is initialized, that means when its initial full address IFADDRx and its initial frame counter IFTCOUNT is used. When initializing (restarting) a buffer the information in the corresponding initial DCP RAM is loaded to a internal state machine but not to the current DCP RAM (CFADDRx, CFTCTx). The current DCP RAM is updated the first time when the first frame has finished. A buffer is initialized: • In circular buffer transfer mode (defined by TMBx) when the end of the buffer is reached. • When CPs are switched or enabled according to Buffer Initialization. The CPENA bits (2*x+1) and (2*x) are changed by write access to CPENA. For the first two rows of the table, the change of the CPENA bits could also be the result of the auto switch feature (as defined by TMBx). BIM bit x only affects DCP x (with x = 0,1,...or 7).

Table 24-27. Buffer Initialization

Case	Change of CPENA bits (2*x+1) and (2*x)		Action on buffer A or B (of DCP x)		
	Old state [1]	New state [2]		BIM bit x = 0 (normal mode)	BIM bit x = 1 (special mode)
A	01	10	Switch from CP A to B	Next frame starts at the initial address of buffer B [3]	Same as for BIM bit x = 0
B	10	01	Switch from CP B to A	Next frame starts at the initial address of buffer A [3]	Same as for BIM bit x = 0
C	01	01	Stay at CP A	Write to CPENA bits (2*x+1) and (2*x) is ignored	Same as for BIM bit x = 0
E	10	10	Stay at CP B	Write to CPENA bits (2*x+1) and (2*x) is ignored	Same as for BIM bit x = 0
E	00	01	Enable CP A	Next frame starts at the **initial** address of buffer A	*Next frame continues at the **current** address of buffer A*
F	00	10	Enable CP B	Next frame starts at the **initial** address of buffer B	*Next frame continues at the **current** address of buffer B*
G	xx	11	Disable both CPs	Stop DCP x	Same as for BIM bit x = 0

(1) See read table of CPENA register (Table 24-14).
(2) See write table of CPENA register (Table 24-13).
(3) This is regardless of whether the switch is done by a write access to CPENA or by the auto-switch feature.

Copyright © 2018, Texas Instruments Incorporated

NOTE: For cases E and F above, after the last frame of a buffer, the HTU sets CFTCTx to 0 and CFADDRx to the next address after the buffer. If the DCP was disabled during this state, then both CFTCTx and CFADDRx would contain invalid initialization values. Therefore, if a DCP should continue at its current address, then the software should use one of the following two procedures before it (re-) enables the DCP (as per Table 24-27):

```
1.  If CFTCTx ≠ 0 then set BIM=1
    If CFTCTx = 0 then set
                      BIM=0
2.  If CFTCTx ≠ 0 then set
                      BIM=1
    If CFTCTx = 0 then {set
                      BIM=1;

set CFTCTx = IFTCOUNT;
set CFADDRx = IFADDRx}
```

But note that these procedures are only required for the cases E and F and not for all the other cases shown in Table 24-27. Also, when a buffer reaches its end in circular mode, it uses the initial DCP information to restart independently of the BIM setting (assuming it is not temporarily disabled during CFTCTx = 0).

NOTE: Similarly, care needs to be taken when BIM is set to 1 and a DCP is enabled for the very first time. Also, in this case, CFTCTx and CFADDRx usually contain invalid initialization values. The software can either solve this by setting BIM = 0 for the first time or setting CFADDRx to IFADDRx and CFTCTx to IFTCOUNT before the DCP is enabled.

NOTE: If

- the HTUEN bit is changed to 1 after the HTU was disabled HTUEN = 0
- the CPENA bit pair is 01 or 10 (during this HTUEN change)

then the corresponding BIM bit will decide if the corresponding buffer continues at its initial or current address. Cases E and F in Table 24-27 also apply for this situation. The software should use the procedures explained in the first note before setting HTUEN.

Table 24-29. Buffer Full Interrupt Flag Register (HTU BFINTFL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0. Writes have no effect.
15-0	BFINTFL		Buffer Full Interrupt Flags
		0	No buffer full condition is detected. Writing a 0 has no effect.
		1	If bit (2*x) is set, a buffer full condition on CP A of DCP x has been detected. If bit (2*x+1) is set, a buffer full condition on CP B of DCP x has been detected. The BFINTFL flag is set after the last frame finishes on the corresponding buffer regardless of whether the buffer is configured to one shot, circular or auto-switch mode. If BFINTFL is set in circular mode, then a circular overrun has occurred on the corresponding buffer. This can be used to indicate whether the buffer section after the frozen full address contains valid data or not. Reading from INTOFFx in case of a buffer-full interrupt clears the corresponding flag. The state of the flag bit can be polled even if the corresponding interrupt enable bit is cleared. • Reading BFINTFL will not clear the flags or • Reading INTOFFx will clear the corresponding flags or • Writing a 1 clears the corresponding flag.

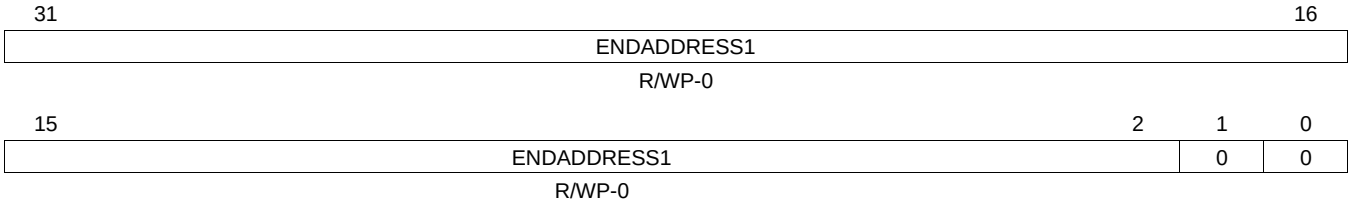
24.4.18 Memory Protection 1 Start Address Register (HTU MP1S)

This register configures the start address of memory protection region 1.

Figure 24-31. Memory Protection 1 Start Address Register (HTU MP1S) [offset = 4Ch]



LEGEND: R/W = Read/Write; WP = Write in privilege mode only; -*n* = value after reset

Table 24-31. Memory Protection 1 Start Address Register (HTU MP1S) Field Descriptions

Bit	Field	Description
31-0	STARTADDRESS1	The start address defines at which main memory address the region begins. A memory protection error will be triggered, if the HTU accesses an address smaller than STARTADDRESS1 and the MPCS bit REG01ENA register is configured accordingly. The address is 32-bit aligned, so the 2 LSBs are not significant and will always read 0.

24.4.19 Memory Protection 1 End Address Register (HTU MP1E)

Figure 24-32. Memory Protection 1 End Address Register (HTU MP1E) [offset = 50h]

LEGEND: R/W = Read/Write; WP = Write in privilege mode only; -*n* = value after reset

Table 24-32. Memory Protection 1 End Address Register (HTU MP1E) Field Descriptions

Bit	Field	Description
31-0	ENDADDRESS1	The end address defines at which address the region ends. A memory protection error will be triggered, if the HTU accesses an address bigger than ENDADDRESS1 and the register bit REG01ENA is configured accordingly. The address is 32-bit aligned, so the 2 LSBs are not significant and will always read 0. The effective end address is rounded up to the nearest word end address, that is, 0x200 = 0x203.

24.4.21 Watch Point Register (HTU WPR)

This register defines the main memory address of the watch point.

Figure 24-34. Watch Point Register (HTU WPR) [offset = 58h]

31	16
WP	
R/WS-0	

15	0
WP	
R/WS-0	

LEGEND: R/W = Read/Write; WS = Write in suspend mode only; -*n* = value after reset

Table 24-34. Watch Point Register (HTU WPR) Field Descriptions

Bit	Field	Description
31-0	WP	Watch Point Register A 32-bit address can be programmed into this register as a watch point. The WPR register is used along with the Watch Mask Register (WMR). When the main memory address is equal to the unique address defined by WPR, or lies in the specified range resulting from WMR, then the HTUDBGS is set. If in addition DBREN is set, then the application code execution is stopped. This register can only be programmed during debug mode. This register and all other bits of the DCTRL and WMR registers are reset by the test reset (nTRST) but not by the normal device reset.

24.4.22 Watch Mask Register (HTU WMR)

This register defines a mask of the main memory address of the watch point. It can be used to define a memory range in conjunction with the WPR register.

Figure 24-35. Watch Mask Register (HTU WMR) [offset = 5Ch]

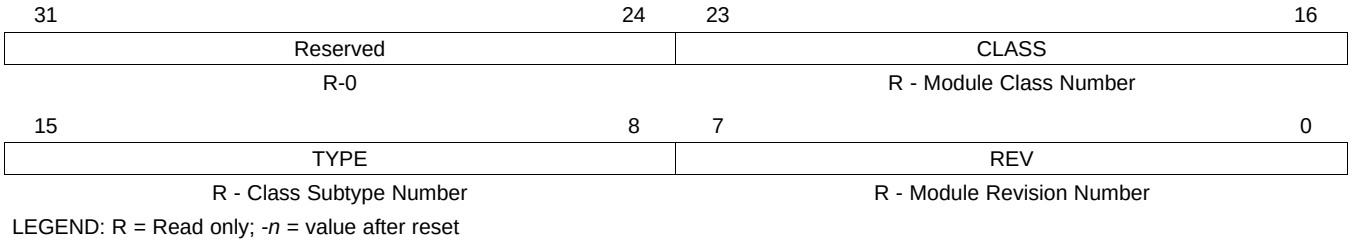
Table 24-35. Watch Mask Register (HTU WMR) Field Descriptions



Bit	Field	Description
31-0	WM	Watch Mask Register Setting a bit in the WMR register to 1 has the effect of masking the corresponding bit in of the main memory address, so that this bit is ignored for the address comparison. This register can only be programmed during debug mode. This register and all other bits of the DCTRL and WPR registers are reset by the test reset (nTRST) but not by the normal device reset.

24.4.23 Module Identification Register (HTU ID)

This register is for TI internal purposes and allows to keep track of the HTU module version on different devices.

Figure 24-36. Module Identification Register (HTU ID) [offset = 60h]

LEGEND: R = Read only; -*n* = value after reset

Table 24-36. Module Identification Register (HTU ID) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reads return 0. Writes have no effect.
23-16	CLASS		Module Class This field defines the module class number as read-only constant value for the HTU module. Writes have no effect.
15-8	TYPE		Subtype within a Class This field defines the subtype within a class as read-only constant value for the HTU module. Writes have no effect.
7-0	REV		Module Revision Number This field defines the module revision number as read-only constant value for the HTU module. Writes have no effect.

24.4.24 Parity Control Register (HTU PCR)

Figure 24-37. Parity Control Register (HTU PCR) [offset = 64h]

31	17	16
Reserved		COPE
R-0		R/WP-0

15	9	8	7	4	3	0
Reserved		TEST	Reserved		PARITY_ENA	
R-0		R/WP-0	R-0		R/WP-5h	

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

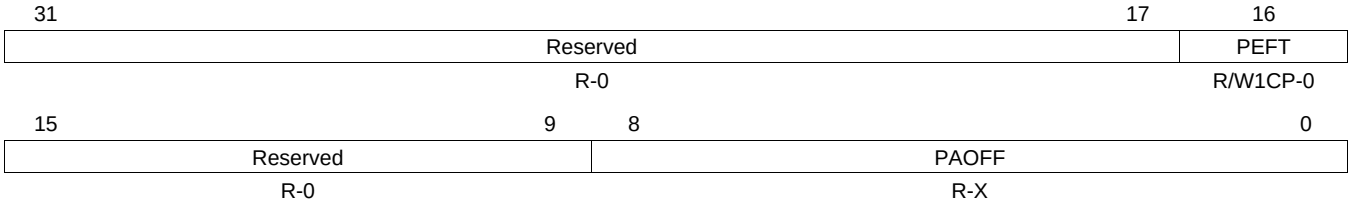

Table 24-37. Parity Control Register (HTU PCR) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reads return 0. Writes have no effect.
16	COPE		Continue on Parity Error
		0	The HTU performs parity checks every time it reads the RAM section of DCP x (with x = 0, 1,... or 7), before the next frame (of DCP x) is started. If a parity error is detected during this read access and if the parity check is enabled, then the frame will not be started and DCP x will be automatically disabled in the CPENA register. If a master different than the HTU (for example, CPU) reads the RAM section of DCP x and a parity error is detected during this read access, while the parity check is enabled, then the DCP x will automatically be disabled in the CPENA register. If a frame is active on DCP x during this read access, then in addition the element counter of DCP x is cleared and all new element transfers on DCP x are stopped and the active busy bit of DCP x is cleared.
		1	The difference to COPE = 0 is, that the data transfer on a active DCP continues after a parity error was detected on this DCP. So, neither the DCP with the parity error will be disabled nor the frame will be stopped.
15-9	Reserved	0	Reads return 0. Writes have no effect.
8	TEST		Test. When this bit is set, the parity bits are mapped into the peripheral RAM frame to make them accessible by the CPU.
		0	Parity bits are not memory-mapped.
		1	Parity bits are memory-mapped.
7-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	PARITY_ENA		Enable/Disable Parity Checking. This bit field enables or disables the parity check on read operations and the parity calculation on write operations. If parity checking is enabled and a parity error is detected, then the PEFT flag is set, PAOFF is captured if it is not currently frozen and an interrupt is generated if it is enabled.
		5h	Parity check is disabled.
		All Others	Parity check is enabled. **Note:** It is recommended to write Ah to enable error detection, to guard against single bit changes from flipping PARITY_ENA to a disable state.

24.4.25 Parity Address Register (HTU PAR)

Figure 24-38. Parity Address Register (HTU PAR) [offset = 68h]

LEGEND: R/W = Read/Write; R = Read only; W1CP = Write 1 in privilege mode to clear the bit; -*n* = value after reset; X = undefined

Table 24-38. Parity Address Register (HTU PAR) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads return 0. Writes have no effect.
16	PEFT		Parity Error Fault Flag. This bit is set, when the HTU detects a parity error and parity checking is enabled.
		0	No fault is detected.
		1	Fault is detected.
			Note: Once PEFT is set, a read access to the lower 16 bits or to the complete 32-bit HTUPAR register will clear the PEFT flag in non-debug mode. Another possibility to clear PEFT is to write a 1 to the PEFT bit.
15-9	Reserved	0	Reads return 0. Writes have no effect.
8-0	PAOFF		Parity Error Address Offset. This bit field holds the address of the first parity error, which is detected in the DCP RAM. PAOFF provides the offset address of the erroneous byte counted from the beginning of the DCP memory. This error address is frozen from being updated until a read access to the lower 16 bits or to the complete 32-bit HTUPAR register happens. During debug mode, this address is frozen even when read.
			Note: The Parity Error Address bits will not be reset, neither by PORRST nor by any other reset source.

Copyright © 2018, Texas Instruments Incorporated

24.4.26 Memory Protection Control and Status Register (HTU MPCS)

		Bh	CP B of DCP5
		Ch	CP A of DCP6
		Dh	CP B of DCP6
		Eh	CP A of DCP7
		Fh	CP B of DCP7
23-18	Reserved	0	Reads return 0. Writes have no effect.
17	MPEFT1		Memory Protection Error Fault Flag 1. This bit is set, when the HTU performs an access outside the region defined by the MP0S and MP0E and the MP1S and MP1E registers, when the access violates the rights defined by ACCR01, and when the REG01ENA bit is set.
		0	No fault detected. Writing a 0 has no effect.
		1	Fault detected. Writing a 1 will clear the bit.
16	MPEFT0		Memory Protection Error Fault Flag 0. This bit is set, when the HTU performs an access outside the region defined by the MP0S and MP0E registers, when the access violates the rights defined by ACCR, and when the REG0ENA bit is set.
		0	No fault detected. Writing a 0 has no effect.
		1	Fault detected. Writing a 1 will clear the bit.

Table 24-39. Memory Protection Control and Status Register (HTU MPCS) Field Descriptions (continued)

Bit	Field	Value	Description
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	CPNUM1		Control Packet Number for single memory protection region configuration. CPNUM1 holds the number of the CP, which has caused the first memory protection error when only one memory protection region is used. This number is not updated for multiple access violations until it is read by the CPU. During debug mode, CPNUM1 is frozen even when read.
		0	CP A of DCP0
		1h	CP B of DCP0
		2h	CP A of DCP1
		3h	CP B of DCP1
		4h	CP A of DCP2
		5h	CP B of DCP2
		6h	CP A of DCP3
		7h	CP B of DCP3
		8h	CP A of DCP4
		9h	CP B of DCP4
		Ah	CP A of DCP5
		Bh	CP B of DCP5
		Ch	CP A of DCP6
		Dh	CP B of DCP6
		Eh	CP A of DCP7
		Fh	CP B of DCP7
7-6	Reserved	0	Reads return 0. Writes have no effect.
5	INTENA01		Interrupt Enable 01. This bit needs to be set when working with two memory-mapped regions and a error should be generated to the ESM module on an access violation.
		0	Error signaling is disabled.
		1	Error signaling is enabled.
4	ACCR01		Access Rights 01. This bit defines the access rights for the HTU for accesses outside the region defined by the MP0S and MP0E and the MP1S and MP1E registers.
		0	HTU read access is allowed but write access will be signaled.
		1	Any access performed by the HTU is forbidden and will be signaled.
3	REG01ENA		Region Enable 01. This bit needs to be set when working with two memory-mapped regions. **REG0ENA must be cleared to 0** if this bit is set to a 1. Memory region 0 must be less than memory region 1.
		0	The protection outside the memory region defined by the MP0S and MP0E and the MP1S and MP1E registers is not enabled. This means the HTU can access any implemented memory space. REG0ENA could still enabled to give protection outside the MP0S:MP0E region.
		1	The protection outside the memory region defined by the MP0S and MP0E and the MP1S and MP1E registers is enabled. This means the HTU can perform any access within the regions, but if it attempts to perform a forbidden access outside of both of the regions (according to the ACCR01 configuration), the access is signaled by the MPEFT1 flag. The number of the CP, which has caused the memory protection error, is captured to CPNUM1 if it is not currently frozen and an error is generated if it is enabled.
2	INTENA0		Interrupt Enable 0. This bit needs to be set when working with one memory-mapped region and a error should be generated to the ESM module on an access violation.
		0	Error signaling is disabled.
		1	Error signaling is enabled.
1	ACCR		Access Rights 0. This bit defines the access rights for the HTU for accesses outside the region defined by the MP0S and MP0E registers for a single memory protection region configuration.
		0	HTU read access is allowed but write access will be signaled.
		1	Any access performed by the HTU is forbidden and will be signaled.

Table 24-40. Memory Protection 0 Start Address Register (HTU MP0S) Field Descriptions

Bit	Field	Description
31-0	STARTADDRESS0	The start address defines at which main memory address the region begins. A memory protection error will be triggered, if the HTU accesses an address smaller than STARTADDRESS0 and the MPCS register is configured accordingly. The address is 32-bit aligned, so the 2 LSBs are not significant and will always read 0.

LEGEND: R/W = Read/Write; WP = Write in privilege mode only; -*n* = value after reset

Table 24-41. Memory Protection End Address Register (HTU MP0E) Field Descriptions

Bit	Field	Description
31-0	ENDADDRESS0	The end address defines at which address the region ends. A memory protection error will be triggered, if the HTU accesses an address bigger than ENDADDRESS0 and the register bit MPCS register is configured accordingly. The address is 32-bit aligned, so the 2 LSBs are not significant and will always read 0. The effective end address is rounded up to the nearest word end address, that is, 0x200 = 0x203.

24.5 Double Control Packet Configuration Memory

All bits marked "reserved' are implemented in RAM and will be initialized to unknown values after power on. Reserved locations can be written and read but should be written with 0 to ensure future compatibility. The HTU RAM can be cleared with the system RAM initialization function.

Table 24-42 provides a summary of the memory configuration. There are eight sets of DCP registers and eight sets of CF registers. The base address for the DCP registers is FF4E 0000h for HTU1 and FF4C 0000h for HTU2.

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset; X = Unknown

Table 24-45. Initial N2HET Address and Control Register (HTU IHADDRCT) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reads return 0. Writes have no effect.
23	DIR		Direction of Transfer
		0	N2HET address is read and main memory address is written.
		1	Main memory address is read and N2HET address is written.
22	SIZE		Size of Transferred Data
		0	32-bit transfer
		1	64-bit transfer
			64-bit transfer examples: If the N2HET address points to the N2HET instruction Control Field (CF), then the CF and Data Field (DF) will be transferred. If the N2HET address points to the Program Field (PF), then the PF and CF will be transferred.
21	ADDMH		Addressing Mode N2HET Address. This bit determines the N2HET address index from one to the next element of a frame.
		0	Increment by 16 bytes.
			Examples:
			If the initial N2HET address points to data field of instruction (n). Then the N2HET fields to be transferred by the elements of a frame are: data field of instruction (n), data field of instruction (n+1), data field of instruction (n+2) and so on. If the initial N2HET address points to control field of instruction (n), then the N2HET fields to be transferred by the elements of a frame are: control field of instruction (n), control field of instruction (n+1), control field of instruction (n+2) and so on.
		1	Increment by 8 bytes.
			This mode is intended to be used together with the 64-bit transfer size to load short N2HET instruction blocks into the N2HET RAM. So the sequence of transferred 64-bit elements could be: [PF and CF of instruction (n)], [DF and RF of instruction (n)], [PF and CF of instruction (n+1)], [DF and RF of instruction (n+1)] and so on.
20	ADDMF		Addressing Mode Main Memory Address
		0	Post-increment
			Note: When post-increment is selected the HTU will automatically increment by 4 bytes for a 32-bit data size and by 8 bytes for a 64-bit data size.
		1	Constant
19-18	TMBA		Transfer Mode for Buffer A
		0	One-Shot buffer mode
		1h	Circular buffer mode
		2h-3h	Auto Switch mode
17-16	TMBB		Transfer Mode for Buffer B
		0	One-Shot buffer mode
		1h	Circular buffer mode
		2h-3h	Auto Switch mode

Copyright © 2018, Texas Instruments Incorporated

Table 24-45. Initial N2HET Address and Control Register (HTU IHADDRCT) Field Descriptions (continued)

Bit	Field	Value	Description
15-13	Reserved	0	Reads return 0. Writes have no effect.
12-2	IHADDR		Initial N2HET Address The initial N2HET Address points to the N2HET field, which is the first element of the frame. The N2HET address (bits 12:2) increments by 1 for each 32-bit N2HET field and starts with 0 at the first 32-bit field in the N2HET RAM. **Note:** When the HTU addresses the N2HET RAM it uses only the number of address bits required for the actual N2HET RAM size. If the N2HET address exceeds the actual N2HET RAM size, the unused MSB bits of the address will be ignored and the address rolls over to the start of the N2HET RAM.
1-0	Reserved	0	Reads return 0. Writes have no effect.

Table 24-47. Current Full Address A Register (HTU CFADDRA) Field Descriptions

Bit	Field	Description
31-0	CFADDRA	Current (byte) Address of Buffer A The current main memory address register is updated at the end of each frame. Therefore it points to the start address of the frame, which is the next to transfer, if currently no frame is transferred on this DCP. For an ongoing frame transfer, it points to the start address of this frame. After the last element of a buffer was transferred it will point to the buffer end address plus 0x4. The main purpose of the current full address registers for buffer A and buffer B (see next section) is to enable the software to find out the recently transferred element in the frozen buffer while the address of the active buffer increments. **Note:** A frame can be automatically stopped if any of the events listed in Conditions for Frame Transfer Interruption happens. If a frame is stopped before it could complete, then the current full address register is not updated and it will point to the start of the bad frame after the DCP was automatically disabled.

To transfer the first frame of buffer x, the information in the corresponding initial DCP RAM (IFADDRx, IHADDRCT, ITCOUNT) is loaded to an internal state machine but not to the current DCP RAM (CFADDRx, CFTCTx).

This is valid for all of the following modes:

- Buffer x has reached it's end in circular mode and rolls back to its start address.
- CP x is enabled by a CPENA access (and corresponding BIM bit is 0).
- A CPENA access or auto-switch mode causes a switch from CP y to CP x.

This means after starting the transfer to/from buffer x, CFADDRx and CFTCTx is not updated before the end of the first frame. So before the software switches from CP y to CP x using a write access to the CPENA register, it needs to initialize CFADDRx, CFTCTx. This allows the software to find out if the next request on CP x after the switching to CP x was delayed or never occurring.

Table 24-48. Current Full Address B Register (HTU CFADDRB) Field Descriptions

Bit	Field	Description
31-0	CFADDRB	Current (byte) Address of Buffer B The current main memory address register is updated at the end of each frame. Therefore it points to the start address of the frame, which is the next to transfer, if currently no frame is transferred on this DCP. If currently a frame is transferred, then it points to the start address of this frame. After the last element of a buffer was transferred it will point to the buffer end address plus 0x4. The main purpose of the current full address registers for buffer A and buffer B (see next section) is to enable the software to find out the recently transferred element in the frozen buffer while the address of the active buffer increments. **Note:** A frame can be automatically stopped if any of the events listed in Conditions for Frame Transfer Interruption happens. If a frame is stopped before it could complete, then the current full address register is not updated and it will point to the start of the bad frame after the DCP was automatically disabled.

To transfer the first frame of buffer x, the information in the corresponding initial DCP RAM (IFADDRx, IHADDRCT, ITCOUNT) is loaded to an internal state machine but not to the current DCP RAM (CFADDRx, CFTCTx).

This is valid for all of the following modes:

- Buffer x has reached it's end in circular mode and rolls back to its start address.
- CP x is enabled by a CPENA access (and corresponding BIM bit is 0).
- A CPENA access or auto-switch mode causes a switch from CP y to CP x.

This means after starting the transfer to/from buffer x, CFADDRx and CFTCTx is not updated before the end of the first frame. So before the software switches from CP y to CP x using a write access to the CPENA register, it needs to initialize CFADDRx, CFTCTx. This allows the software to find out if the next request on CP x after the switching to CP x was delayed or never occurring.

24.5.7 Current Frame Count Register (HTU CFCOUNT)

The current frame count register enables the software to find out the recent frame in the buffer while the counter of the active buffer decrements.

Figure 24-48. Current Frame Count Register (HTU CFCOUNT)

31	24	23	16
Reserved		CFTCTA	
R-0		R/WP-X	

15	8	7	0
Reserved		CFTCTB	
R-0		R/WP-X	

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset; X = Unknown

Table 24-49. Current Frame Count Register (HTU CFCOUNT) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reads return 0. Writes have no effect.
23-16	CFTCTA		Current Frame Transfer Count for CP A. It is updated at the end of each frame.
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	CFTCTB		Current Frame Transfer Count for CP B. It is updated at the end of each frame.

24.6 Examples

24.6.1 Application Examples for Setting the Transfer Modes of CP A and B of a DCP

Table 24-50. Application Examples for Setting the Transfer Modes of CP A and B of a DCP

CP A	CP B	
One shot	Not used	Buffer A can be used as a "one shot" buffer. A buffer full interrupt enabled for CP A can signal reaching the end of the buffer.
Auto switch	One shot	Can double the buffer size for a "one shot" buffer. A buffer full interrupt enabled for CP B can signal reaching the end of the buffer.
Circular	Circular	The CPU can switch the buffers at arbitrary times. It will fill or read the frozen buffer during the other buffer is filled or read by the HTU. Interrupts are not required for this case.
Auto switch	Auto switch	Buffer full interrupts (enabled for CP A and B) signal when the end of a buffer is reached. After one buffer is completed the according CPU interrupt routine will read or refill this buffer. At the same time the other buffer is read or filled by the HTU. Here the time when the buffer must be read is determined by the time of the interrupt (determined by the frequency of the N2HET transfer requests).

24.6.2 Software Example Sequence Assuming Circular Mode for Both CP A and B

The example assumes the N2HET address to be read and the main memory address to be written.

I1 CPU initializes initial DCP: IFADDRA, IFADDRB, IHADDRCT, ITCOUNT
I2 CPU clears current DCP: CFADDRA, CFADDRB, CFTCTA, CFTCTB
I3 CPU clears BFINTFL flag of CP A and B
I4 Enable CP A with the CPENA register. Now the HTU fills buffer A

After some time the CPU intends to read buffer A:

A1 CPU enables CP B and disables CP A by writing to the CPENA register. After this switch, the HTU fills buffer B. Filling buffer B starts with its initial full address and initial frame counter.
A2 CPU waits for CP A busy bit equals 0
A3 Optional: CPU verifies that the CP A request lost flag is not set. The bus error flag of CP A could also be checked.
A4 CPU reads the frozen CFTCTA, which indicates the fill level in the buffer
A5 CPU sets current CP A (CFTCTA and/or CFADDRA) to 0. This allows to find out if any request has happened during the next time buffer A is active.
A6 CPU reads BFINTFL flag of buffer A
A7 CPU clears the BFINTFL flag of buffer A. This is an initialization for the next time buffer A is used.
A8 CPU reads valid values of frozen buffer A. After reading the CPU does not need to clear the frozen buffer A.

Copyright © 2018, Texas Instruments Incorporated

After some time the CPU intends to read buffer B:

B1	CPU enables CP A and disables CP B by writing to the CPENA register. After this switch, the HTU fills buffer A. Filling buffer A starts with its initial full address and initial frame counter.
B2	CPU waits for CP B busy bit equals 0
B3	Optional: CPU verifies that the CP B request lost flag is not set. The bus error flag of CP B could also be checked.
B4	CPU reads the frozen CFTCTB, which indicates the fill level in the buffer
B5	CPU sets current CP B (CFTCTB and/or CFADDRB) to 0. This allows to find out if any request has happened during the next time buffer B is active.
B6	CPU reads BFINTFL flag of buffer B
B7	CPU clears the BFINTFL flag of buffer B. This is an initialization for the next time buffer B is used.
B8	CPU reads valid values of frozen buffer B. After reading the CPU does not need to clear the frozen buffer B.

After some time the CPU intends to read buffer A:

A1) ... see above...

NOTE: The buffer full interrupt doesn't need to be enabled. The BFINTFL flag is used to indicate a circular overrun of the buffer. If the BFINTFL flag is set, also the buffer section after the frozen full address could be read.

Steps A3 and B3 in the example sequence above imply that request lost interrupts are disabled. The example below assumes that request lost interrupts are enabled.

Request lost detection with interrupt enabled.

24.6.3 Example of an Interrupt Dispatch Flow for a Request Lost Interrupt

- A request lost occurs and the interrupt routine starts.
- Reading INTOFFx.INTYPEx shows that RLOSTFL is the interrupt source.
- Reading INTOFFx.CPOFFx = Ah shows that DCP 5 / CP A has caused the RLOSTFL interrupt. The hardware automatically clears bit (2·5+0) in RLOSTFL.
- Reading RLOSTFL= 84h shows that also another request lost event happened on DCP 1 / CP A [bit (2·1+0)] and on DCP 3 / CP B [bit (2·3+1)] at the same time or after the request lost occurred on DCP 5 / CP A.
- Writing back 84h to RLOSTFL clears bits 2 and 7 and the according pending interrupts.

General-Purpose Input/Output (GIO) Module

This chapter describes the general-purpose input/output (GIO) module. The GIO module provides the family of devices with input/output (I/O) capability. The I/O pins are bidirectional and bit-programmable. The GIO module also supports external interrupt capability.

Topic **Page**

25.1 Overview **1184**

25.5 GIO Control Registers **1191**
25.6 I/O Control Summary **1209**

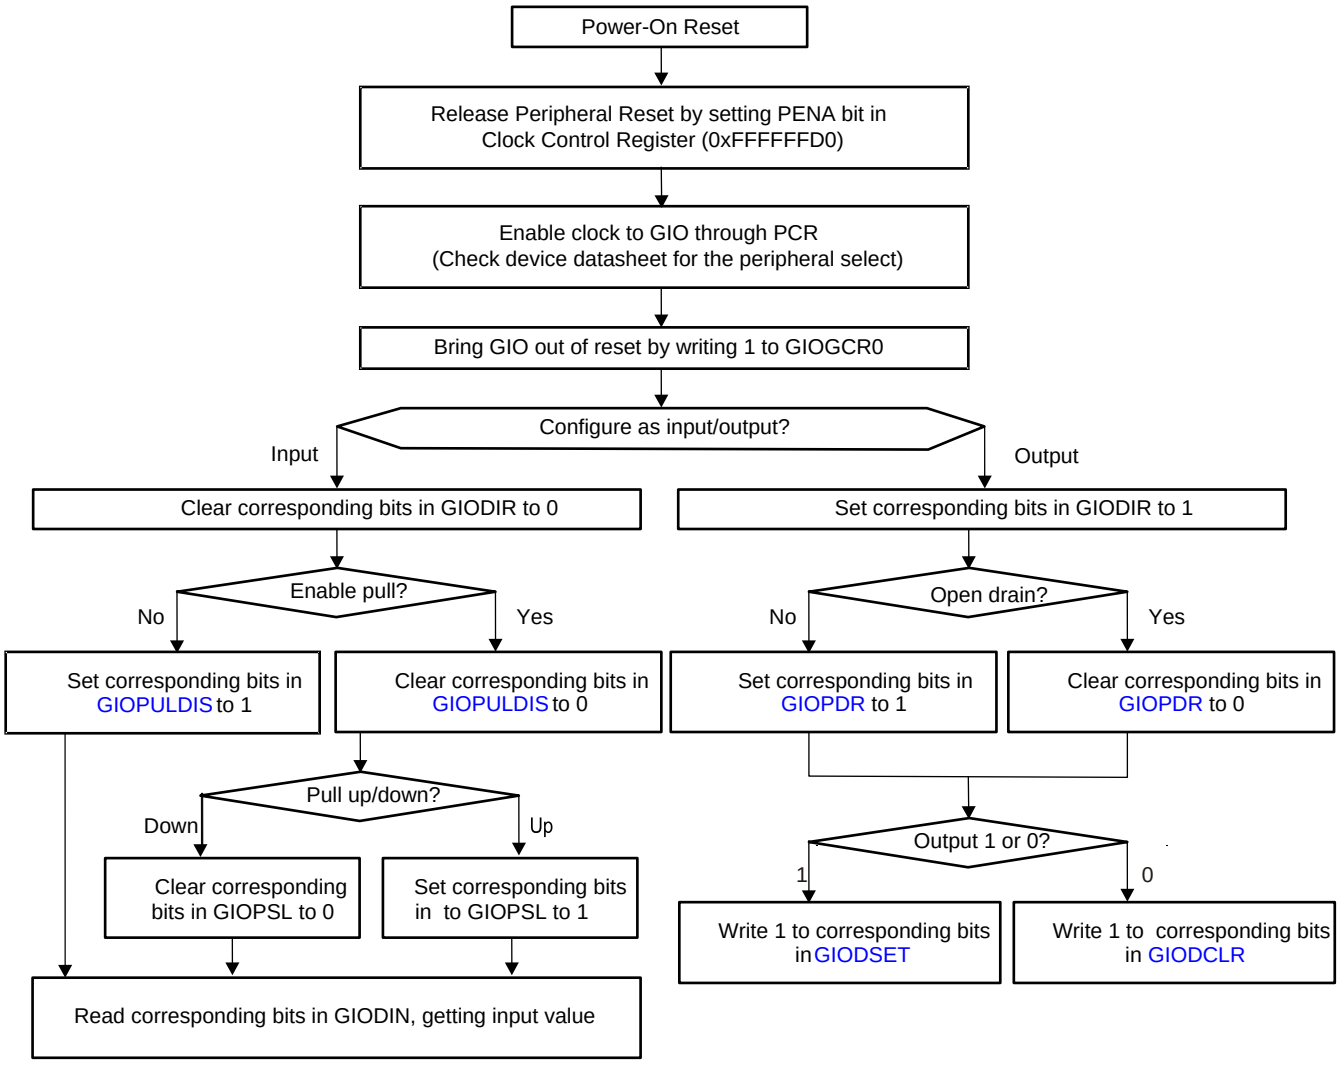
Copyright © 2018, Texas Instruments Incorporated

25.1 Overview

The GIO module offers general-purpose input and output capability. It supports up to eight 8-bit ports for a total of up to 64 GIO terminals. Each of these 64 terminals can be independently configured as input or output and configured as required by the application. The GIO module also supports generation of interrupts whenever a rising edge or falling edge or any toggle is detected on up to 32 of these GIO terminals. Refer to the device datasheet for identifying the number of GIO ports supported and the GIO terminals capable of generating an interrupt.

The main features of the GIO module are summarized as follows:

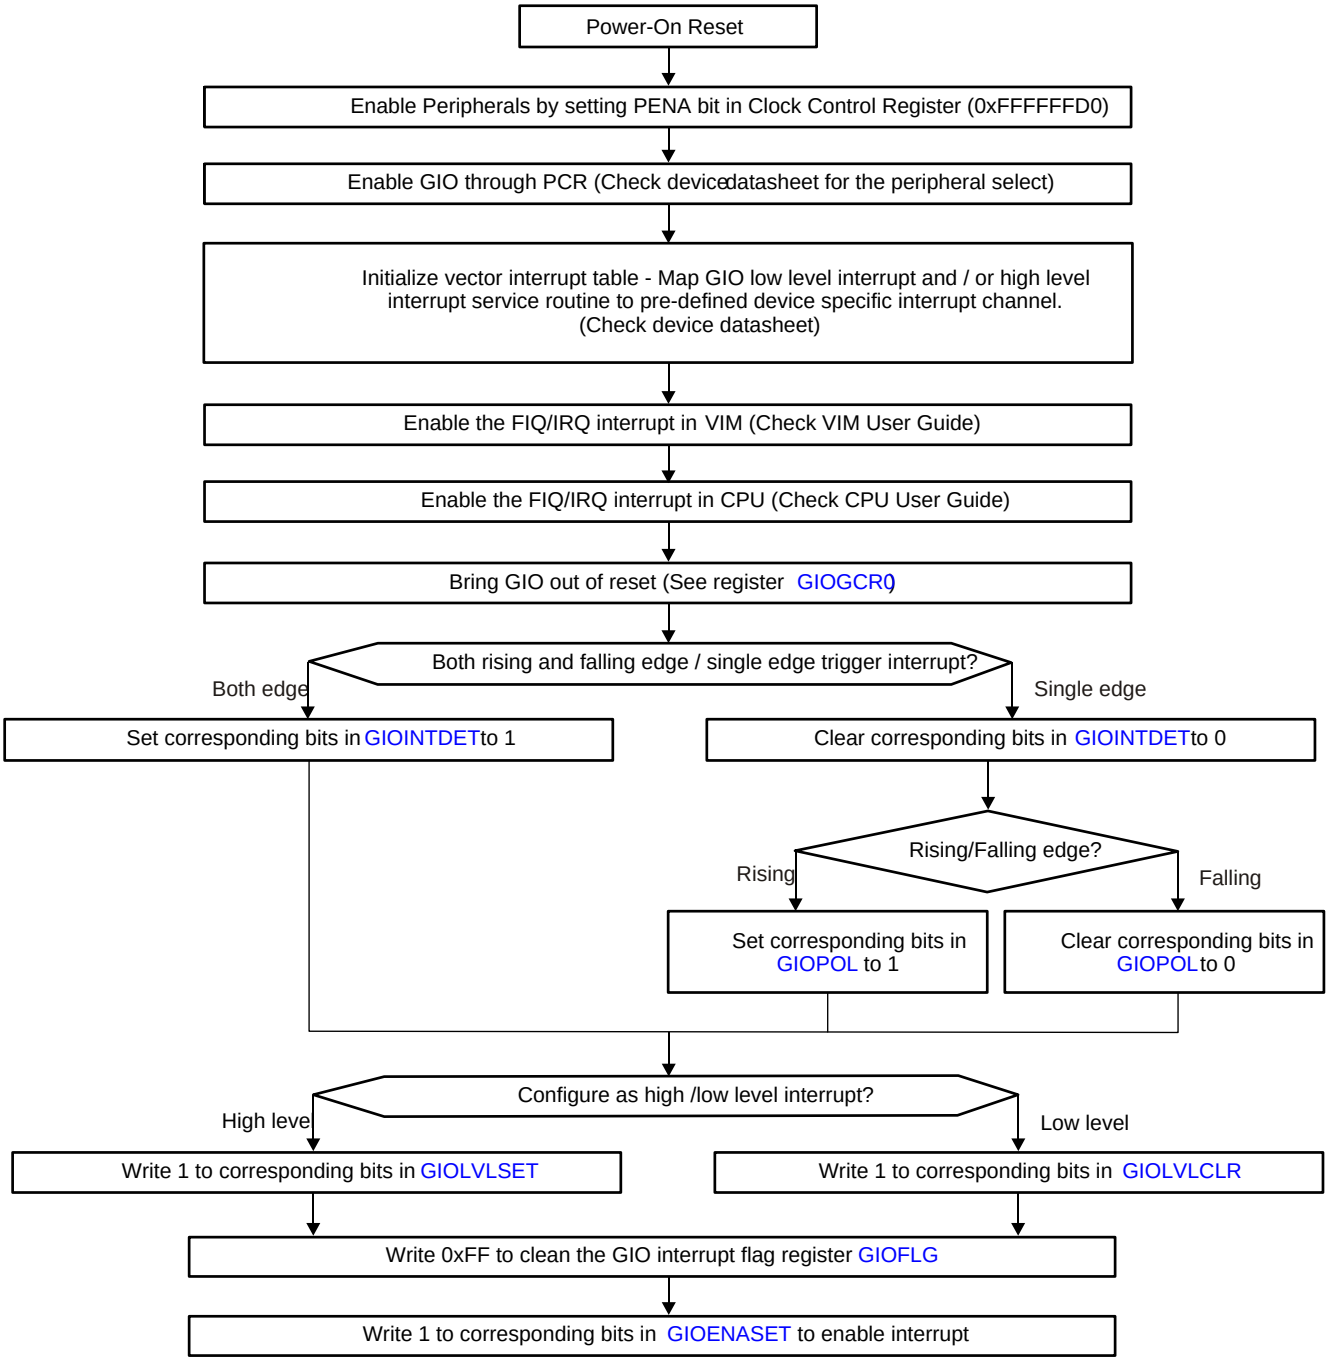
- Allows each GIO terminal to be configured for general-purpose input or output functions
- Supports programmable pull directions on each input GIO terminal
- Supports GIO output in push/pull or open-drain modes
- Allows up to 32 GIO terminals to be used for generating interrupt requests



Copyright © 2018, Texas Instruments Incorporated

25.2 Quick Start Guide

The GIO module comprises two separate components: an input/output (I/O) block and an interrupt generation block. Figure 25-1 and Figure 25-2 show what you should do after reset to configure the GIO module as I/O or for generating interrupts.



In GIO interrupt service routine, you shall read the GIO offset register (GIOOFF1 or GIOOFF2, depending on high-/low-level interrupt) to clear the flag and find the pending interrupt GIO channel.

25.3 Functional Description of GIO Module

As shown in Figure 25-3, the GIO module comprises of two separate components: an input/output (I/O) block and an interrupt block.

Figure 25-3. GIO Module Diagram

25.3.1 I/O Functions

The I/O block allows each GIO terminal to be configured for use as a general-purpose input or output in the application. The GIO module supports multiple registers to control the various aspects of the input and output functions. These are described as follows.

- Data direction (GIODIR)

  Configures GIO terminal(s) as input (default) or output through the GIODIRx registers.

- Data input (GIODIN)

  Reflects the logic level on GIO terminals in the GIODINx registers. A high voltage (V_{IH} or greater) applied to the pin causes a high value (1) in the data input register (GIODIN[7:0]). When a low voltage (V_{IL} or less) is applied to the pin, the data input register reads a low value (0). The V_{IH} and V_{IL} values are device specific and can be found in the device datasheet.

- Data output (GIODOUT)

  Configures the logic level to be output on GIO terminal(s) configured as outputs. A low value (0) written to the data output register forces the pin to a low output voltage (V_{OL} or lower). A high value (1) written to the data output register (GIODOUTx) forces the pin to a high output voltage (V_{OH} or higher) if the open drain functionality is disabled (GIOPDRx[7:0]). If open drain functionality is enabled, a high value (1) written to the data output register forces the pin to a high-impedance state (Z).

- Data set (GIODSET)

  Allows logic HIGH to be output on GIO terminal(s) configured as outputs by writing 1's to the required bits in the GIODSETx registers. If open drain functionality is enabled, a high value (1) written to the data output register forces the pin to a high-impedance state (Z). The GIODSETx registers eliminate the need for the application to perform a read-modify-write operation when it needs to set one or more GIO pin(s).

- Data clear (GIODCLR)

  Allows logic LOW to be output on GIO terminal(s) configured as outputs by writing 1s to the required bits in the GIODCLRx registers. The GIODCLRx registers eliminate the need for the application to perform a read-modify-write operation when it needs to clear one or more GIO pin(s).

- Open drain (GIOPDR)

  Open drain functionality is enabled or disabled (default) using the open drain register GIOPDR[7:0] register. If open-drain mode output is enabled on a pin, a high value (1) written to the data output register (GIODOUTx[7:0]) forces the pin to a high impedance state (Z).

Copyright © 2018, Texas Instruments Incorporated

- Pull disable (GIOPULDIS)

  Disables the internal pull on GIO terminal(s) configured as inputs by writing to the GIOPULDISx registers.
- Pull select (GIOPSL)

  Selects internal pull down (default) or pull up on GIO terminal(s) configured as inputs by writing to the GIOPULSELx registers.

Refer to the specific device's datasheet to identify the number of GIO ports as well as the input and output functions supported. Some devices may not support the programmable pull controls. In that case, the pull disable and the pull select register controls will not work.

25.3.2 Interrupt Function

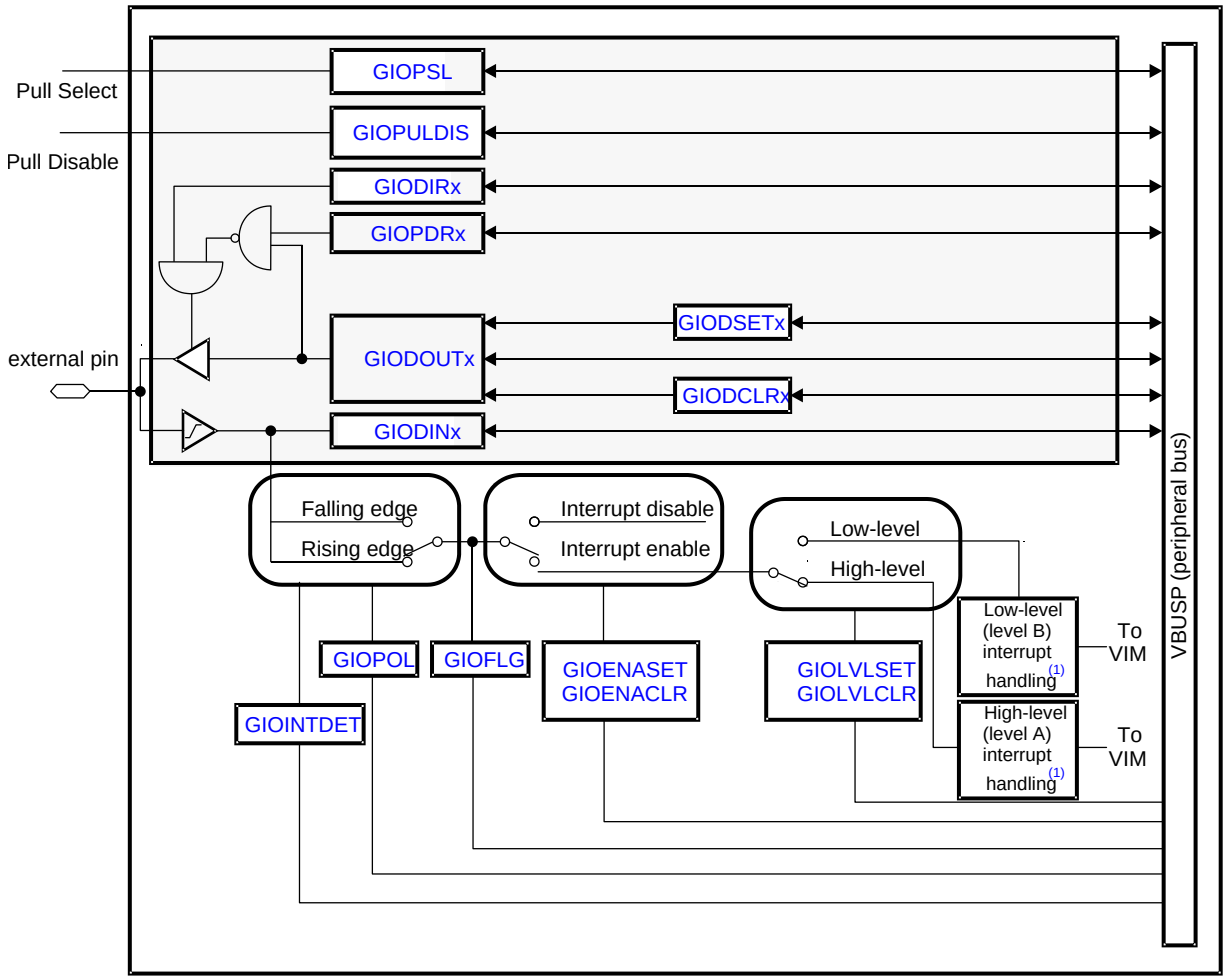
The GIO module supports up to 32 terminals to be configured for generating an interrupt to the host processor through the Vectored Interrupt Manager (VIM). The main functions of the interrupt block are:

- Select the GIO pin(s) that is/are used to generate interrupt(s)

  This is done via the interrupt enable set and clear registers, GIOENASET and GIOENACLR.
- Select the edge on the selected GIO pin(s) that is/are used to generate interrupt(s): rising/falling/both

  Rising or falling edge can be selected via the GIOPOL register. If interrupt is required to be generated on both rising and falling edges, this can be configured via the GIOINTDET register.
- Select the interrupt priority

  Low- or high-level interrupt can be selected through the GIOLVLSET and GIOLVLCLR registers.
- Individual interrupt flags are set in the GIOFLG register



The terminals on GIO ports A through D are all interrupt-capable and can be used to handle either general I/O functions or interrupt requests. Each interrupt request can be connected to the VIM at one of two different levels – High (or A) and Low (or B), depending on the VIM channel number. The VIM has an inherent priority scheme so that a request on a lower number channel has a higher priority than a request on a higher number channel. Refer the device datasheet to identify the VIM channel numbers for the GIO level A and level B interrupt requests. Also note that the interrupt priority of level A and level B interrupt handling blocks can be re-programmed in the VIM.

25.3.3 GIO Block Diagram

The GIO block diagram (Figure 25-4) represents the flow of information through a pin. The shaded area corresponds to the I/O block; the unshaded area corresponds to the interrupt block.

Copyright © 2018, Texas Instruments Incorporated

Figure 25-4. GIO Block Diagram

(1) A single low-level-interrupt-handling block and a single high-level-interrupt-handling block service all of the interrupt-capable external pins, but only one pin can be serviced by an interrupt block at a time.

Copyright © 2018, Texas Instruments Incorporated

25.4 Device Modes of Operation

The GIO module behaves differently in different modes of operation. There are two main modes:

- Emulation mode
- Power-down mode (low-power mode)

25.4.1 Emulation Mode

Emulation mode is used by debugger tools to stop the CPU at breakpoints to read registers.

NOTE: Emulation Mode and Emulation Registers

Emulation mode is a mode of operation of the device and is separate from the GIO emulation registers (GIOEMU1 and GIOEMU2). The contents of these emulation registers are identical to the contents of GIO offset registers (GIOOFF1 and GIOOFF2). Both emulation registers and GIO offset registers are NOT cleared when they are read in emulation mode. GIO offset registers are cleared when they are read in normal mode (other than emulation mode). The emulation registers are NOT cleared when they are read in normal mode. The intention for the emulation registers is that software can use them without clearing the flags.

During emulation mode:

- External interrupts are not captured because the VIM is unable to service interrupts.
- Any register can be read without affecting the state of the system.
- A write to a register still does affect the state of the system.

25.4.2 Power-Down Mode (Low-Power Mode)

In power-down mode, the clock signal to the GIO module is disabled. Thus, there is no switching and the only current draw comes from leakage current. In power-down mode, interrupt pins become level-sensitive rather than edge-sensitive. The polarity bit changes function from falling-edge-triggered to low-level-triggered and rising-edge-triggered to high-level-triggered. A corresponding level on an interrupt pin pulls the module out of low-power mode, if the interrupt is also enabled to wake up the device out of a low-power mode.

25.4.2.1 Module-Level Power Down

The GIO module can be placed into a power down state by disabling the GIO peripheral module via the appropriate bit in the peripheral power down register. Please refer to the Peripheral Central Resource Registers (Section 2.5.3) for details.

25.4.2.2 Device-Level Power Down

The entire device can be placed in one of the pre-defined low-power modes: doze, snooze, or sleep using the clock source and clock domain disable registers in the system module.

Copyright © 2018, Texas Instruments Incorporated

25.5 GIO Control Registers

Table 25-1 shows the summary of the GIO registers. The registers are accessible in 8-, 16-, and 32-bit reads or writes.

The start address for the GIO module is FFF7 BC00h.

The GIO module supports up to 8 ports. Refer to your device-specific data manual to identify the actual number of GIO ports and the number of pins in each GIO port implemented on this device.

The GIO module supports up to 4 interrupt-capable ports. Refer to the device datasheet to identify the actual number of interrupt-capable GIO ports and the number of pins in each GIO port implemented on this device.

25.5.1 GIO Global Control Register (GIOGCR0)

The GIOGCR0 register contains one bit that controls the module reset status. Writing a 0 to this bit puts the module in a reset state. After system reset, this bit must be set to 1 before configuring any other register of the GIO module. Figure 25-5 and Table 25-2 describe this register.

25.5.2 GIO Interrupt Detect Register (GIOINTDET)

The GIO module supports generation of an interrupt request to CPU when a rising edge, falling edge, or both edges is detected on one or more GIO pin(s). The GIOINTDET register allows both rising and falling edges to be detected, while the GIOPOL register allows the application to define whether a rising edge or a falling edge is to be detected. Figure 25-6 and Table 25-3 describe this register.

7-0	GIOINTDET 0		Interrupt detection select for pins GIOA[7:0]
		0	The flag sets on either a falling or a rising edge on the corresponding pin, depending on the polarity setup in the polarity register (GIOPOL).
		1	The flag sets on both the rising and falling edges on the corresponding pin.

Copyright © 2018, Texas Instruments Incorporated

25.5.3 GIO Interrupt Polarity Register (GIOPOL)

The GIOPOL register configures the polarity of the edge, rising edge or falling edge, that needs to be detected. When the device is in low-power mode, the GIOPOL register controls the ***level***, high or low, which will be detected by the GIO module. Figure 25-7 and Table 25-4 describe this register.

25.5.4 GIO Interrupt Enable Registers (GIOENASET and GIOENACLR)

The GIOENASET and GIOENACLR registers control which interrupt-capable pins are actually configured as interrupts. If the interrupt is enabled, the rising edge, falling edge, or both edges on the selected pin lead to an interrupt request.

25.5.4.1 GIOENASET Register

Figure 25-8 and Table 25-5 describe this register.

NOTE: Enabling Interrupt at the Device Level

The interrupt channel in the Vectored Interrupt Manager (VIM) must be enabled for the interrupt request to be forwarded to the CPU. Additionally, the ARM CPU (CPSR bit 7 or 6) must be cleared to respond to interrupt requests (IRQ/FIQ).

25.5.5 GIO Interrupt Priority Registers (GIOLVLSET and GIOLVLCLR)

The GIOLVLSET and GIOLVLCLR registers configure the interrupts as high-level (level A) or low-level (level B) going to the Vectored Interrupt Manager (VIM). Each interrupt is individually configured.

- The high-level interrupts are recorded to GIOOFF1 and GIOEMU1.
- The low-level interrupts are recorded to GIOOFF2 and GIOEMU2.

NOTE: The GIO module can generate two interrupt requests. These are connected to two separate channels on the Vectored Interrupt Manager (VIM). The lower-numbered VIM channels are higher priority. The GIO interrupt connected to a lower-number channel is the high-level (also called level A) GIO interrupt, while the GIO interrupt connected to a higher-number channel is the low-level (also called level B) GIO interrupt.

25.5.5.1 GIOLVLSET Register

The GIOLVLSET register is used to configure an interrupt as a high-level interrupt going to the VIM. An interrupt can be configured as a high-level interrupt by writing a 1 into the corresponding bit of the GIOLVLSET register. Writing a 0 has no effect. Figure 25-10 and Table 25-7 describe this register.

Figure 25-10. GIO Interrupt Priority Register (GIOLVLSET) [offset = 18h]

25.5.5.2 GIOLVLCLR Register

The GIOLVLCLR register is used to configure an interrupt as a low-level interrupt going to the VIM. An interrupt can be configured as a low-level interrupt by writing a 1 into the corresponding bit of the GIOLVLCLR register. Writing a 0 has no effect. Figure 25-11 and Table 25-8 describe this register.

Figure 25-11. GIO Interrupt Priority Register (GIOLVLCLR) [offset = 1Ch]

25.5.6 GIO Interrupt Flag Register (GIOFLG)

The GIOFLG register contains flags indicating that the transition edge (as set in GIOINTDET and GIOPOL registers) has occurred. The flag can be cleared by the CPU writing a 1 to the flag that is set. The flag is also cleared by reading the appropriate interrupt offset register (GIOOFF1 or GIOOFF2). Figure 25-12 and Table 25-9 describe this register.

Figure 25-12. GIO Interrupt Flag Register (GIOFLG) [offset = 20h]

31	24	23	16
GIOFLG 3		GIOFLG 2

LEGEND: R/W = Read/Write; W1C = Write 1 to clear; -*n* = value after reset

Table 25-9. GIO Interrupt Flag Register (GIOFLG) Field Descriptions

Bit	Field	Value	Description
31-24	GIOFLG 3		GIO flag for pins GIOD[7:0]
		0	Read: A transition has not occurred since the last clear.
			Write: Writing a 0 to this bit has no effect.
		1	Read: The selected transition on the corresponding pin has occurred.
			Write: The corresponding bit is cleared to 0.
			Note: This bit is also cleared by a read to the corresponding bit in the appropriate offset register.
23-16	GIOFLG 2		GIO flag for pins GIOC[7:0]
		0	Read: A transition has not occurred since the last clear.
			Write: Writing a 0 to this bit has no effect.
		1	Read: The selected transition on the corresponding pin has occurred.
			Write: The corresponding bit is cleared to 0.
			Note: This bit is also cleared by a read to the corresponding bit in the appropriate offset register.
15-8	GIOFLG 1		GIO flag for pins GIOB[7:0]
		0	Read: A transition has not occurred since the last clear.
			Write: Writing a 0 to this bit has no effect.
		1	Read: The selected transition on the corresponding pin has occurred.
			Write: The corresponding bit is cleared to 0.
			Note: This bit is also cleared by a read to the corresponding bit in the appropriate offset register.
7-0	GIOFLG 0		GIO flag for pins GIOA[7:0]
		0	Read: A transition has not occurred since the last clear.
			Write: Writing a 0 to this bit has no effect.
		1	Read: The selected transition on the corresponding pin has occurred.
			Write: The corresponding bit is cleared to 0.
			Note: This bit is also cleared by a read to the corresponding bit in the appropriate offset register.

NOTE: An interrupt flag gets set when the selected transition happens on the corresponding GIO pin ***regardless of whether the interrupt generation is enabled or not***. It is recommended to clear a flag before enabling the interrupt generation for a transition on the corresponding GIO pin.

25.5.7 GIO Offset Register 1 (GIOOFF1)

The GIOOFF1 register provides a numerical offset value that represents the pending external interrupt with high priority. The offset value can be used to locate the position of the interrupt routine in a vector table in application software. Figure 25-13 and Table 25-10 describe this register.

NOTE: Reading this register clears it, GIOEMU1 and the corresponding flag bit in the GIOFLG register. However, in emulation mode, a read to this register does not clear any register or flag. If more than one GIO interrupts are pending, then reading the GIOOFF1 register will change the contents of GIOOFF1 and GIOEMU1 to show the offset value for the next highest-priority pending interrupt. The application can choose to service all GIO interrupts from the same service routine by continuing to read the GIOOFF1 register until it reads zeros.

25.5.8 GIO Offset B Register (GIOOFF2)

The GIOOFF2 register provides a numerical offset value that represents the pending external interrupt with low priority. The offset value can be used to locate the position of the interrupt routine in a vector table in application software. Figure 25-14 and Table 25-11 describe this register.

NOTE: Reading this register clears it, GIOEMU2 and the corresponding flag bit in the GIOFLG register. However, in emulation mode, a read to this register does not clear any register or flag. If more than one GIO interrupts are pending, then reading the GIOOFF1 register will change the contents of GIOOFF2 and GIOEMU2 to show the offset value for the next highest-priority pending interrupt. The application can choose to service all GIO interrupts from the same service routine by continuing to read the GIOOFF1 register until it reads zeros.

25.5.9 GIO Emulation A Register (GIOEMU1)

The GIOEMU1 register is a read-only register. The contents of this register are identical to the contents of GIOOFF1. The intention for the this register is that software can use it without clearing the flags. Figure 25-15 and Table 25-12 describe this register.

NOTE: The corresponding flag in the GIOFLG register is not cleared when the GIOEMU1 register is read.

25.5.11 GIO Data Direction Registers (GIODIR[A-B])

The GIODIR register controls whether the pins of a given port are configured as inputs or outputs. Figure 25-17 and Table 25-14 describe this register.

Figure 25-17. GIO Data Direction Registers (GIODIR[A-B]) [offset = 34h, 54h]

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

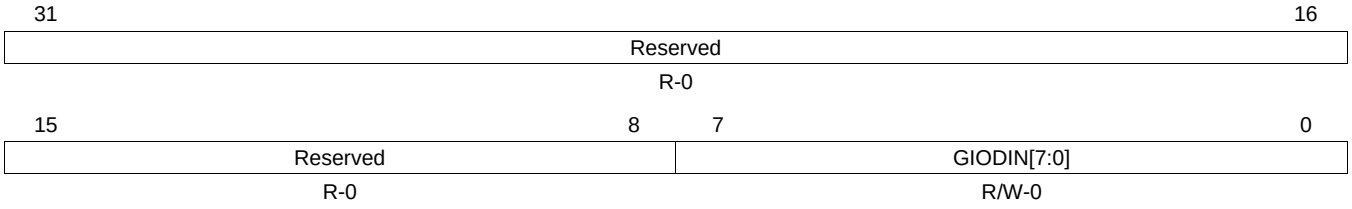

Table 25-14. GIO Data Direction Registers (GIODIR[A-B]) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	GIODIR[*n*]		GIO data direction of port n, pins [7:0]
		0	The GIO pin is an input. Note: If the pin direction is set as an input, the output buffer is tristated.
		1	The GIO pin is an output.

25.5.12 GIO Data Input Registers (GIODIN[A-B])

Values in the GIODIN register reflect the current state (high = 1 or low = 0) on the pins of the port. Figure 25-18 and Table 25-15 describe this register.

Figure 25-18. GIO Data Input Registers (GIODIN[A-B]) [offset = 38h, 58h]

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

25.5.13 GIO Data Output Registers (GIODOUT[A-B])

Values in the GIODOUT register specify the output state (high = 1 or low = 0) of the pins of the port when they are configured as outputs. Figure 25-19 and Table 25-16 describe this register.

NOTE: Values in the GIODSET register set the data output control register bits to 1 regardless of the current value in the GIODOUT bits.

31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	GIODOUT[*n*]		GIO data output of port n, pins[7:0].
		0	The pin is driven to logic low (0).
		1	The pin is driven to logic high (1).
			Note: Output is in high impedance state if the GIOPDRx bit = 1 and GIODOUTx bit = 1.
			Note: GIO pin is placed in output mode by setting the GIODIRx bit to 1.

25.5.14 GIO Data Set Registers (GIODSET[A-B])

Values in this register set the data output control register bits to 1 regardless of the current value in the GIODOUT bits. The contents of this register reflect the contents of GIODOUT. Figure 25-20 and Table 25-17 describe this register.

7-0	GIODSET[*n*]		GIO data set for port n, pins[7:0]. This bit drives the output of GIO pin high.
		0	Write: Writing a 0 has no effect.
		1	Write: The corresponding GIO pin is driven to logic high (1).
			Note: The current logic state of the GIODOUT bit will also be displayed by this bit.
			Note: GIO pin is placed in output mode by setting the GIODIRx bit to 1.

Copyright © 2018, Texas Instruments Incorporated

25.5.15 GIO Data Clear Registers (GIODCLR[A-B])

Values in this register clear the data output register (GIO Data Output Register [A-H]) bit to 0 regardless of its current value. The contents of this register reflect the contents of GIODOUT. Figure 25-21 and Table 25-18 describe this register.

31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	GIODCLR[*n*]		GIO data clear for port n, pins[7:0]. This bit drives the output of GIO pin low.
		0	Write: Writing a 0 has no effect.
		1	Write: The corresponding GIO pin is driven to logic low (0).
			Note: The current logic state of the GIODOUT bit will also be displayed by this bit.
			Note: GIO pin is placed in output mode by setting the GIODIRx bit to 1.

25.5.16 GIO Open Drain Registers (GIOPDR[A-B])

Values in this register enable or disable the open drain capability of the data pins. Figure 25-22 and Table 25-19 describe this register.

25.6 I/O Control Summary

The behavior of the output buffer and the pull control is summarized in Table 25-22.

Table 25-22. Output Buffer and Pull Control Behavior for GIO Pins

Module under Reset?	Pin Direction (GIODIR)[1][2]	Open Drain Enable (GIOPDR)[1][3]	Pull Disable (GIOPULDIS)[1][4]	Pull Select (GIOPSL)[1][5]	Pull Control	Output Buffer[6]
Yes	X	X	X	X	Enabled	Disabled
No	0	X	0	0	Pull down	Disabled
No	0	X	0	1	Pull up	Disabled
No	0	X	1	0	Disabled	Disabled
No	0	X	1	1	Disabled	Disabled
No	1	0	X	X	Disabled	Enabled
No	1	1	X	X	Disabled	Enabled

(1) X = Don't care
(2) GIODIR = 0 for input; = 1 for output
(3) See Section 25.5.16
(4) GIOPULDIS = 0 for enabling pull control; = 1 for disabling pull control
(5) GIOPSL= 0 for pull-down functionality; = 1 for pull-up functionality
(6) If open drain is enabled, output buffer will be disabled if a high level (1) is being output.

FlexRay Module

This chapter provides the specification for TI's FlexRay module and its features from the application programmer's point of view.

Topic **Page**

26.1 Overview **1211**
26.2 Module Operation **1215**
26.3 FlexRay Module Registers **1277**

Copyright © 2018, Texas Instruments Incorporated

26.1 Overview

The FlexRay module performs communication according to the FlexRay protocol specification v2.1 Rev. A. The sample clock bit rate can be programmed to values up to 10 Mbit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

For communication on a FlexRay network, individual message buffers with up to 254 data bytes are configurable. The message storage consists of a single-ported message RAM that holds up to 128 message buffers. All functions concerning the handling of messages are implemented in the message handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay Channel Protocol Controllers and the message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the FlexRay module can be accessed directly by the CPU via the VBUS interface. These registers are used to control, configure and monitor the FlexRay channel protocol controllers, message handler, global time unit, system universal control, frame and symbol processing, network management, interrupt control, and to access the message RAM via the input / output buffer.

26.1.1 Feature List

- Conformance with FlexRay protocol specification v2.1 Rev. A
- Data rates of up to 10 Mbit/s on each channel
- Up to 128 message buffers
- 8 Kbyte of message RAM for storage of, for example, 128 message buffers with maximum of 48-byte data section or up to 30 message buffers with 254-byte data section
- Configuration of message buffers with different payload lengths
- One configurable receive FIFO
- Each message buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO
- CPU access to message buffers via input and output buffer
- Specialized DMA like FlexRay Transfer Unit (FTU) for automatic data transfer between data memory and message buffers without CPU interaction
- Filtering for slot counter, cycle counter, and channel
- Maskable module interrupts
- Supports Network Management

26.1.2 FlexRay Module Block Diagram

The TI FlexRay module, Figure 26-1, contains the following blocks:

- Peripheral Interface (VBUS IF)

  Interface to the Peripheral Bus of the TMS570 microcontroller architecture. The FlexRay module can either act as a VBUS master or VBUS slave.
- FlexRay Transfer Unit (FTU)

  The internal intelligent state-machine (Transfer Unit State Machine) is able to transfer data between the input buffer (IBF) and output buffer (OBF) of the communication controller and the system memory without CPU interaction.

NOTE: Since the FlexRay module is accessed through the FTU, the FTU must be powered up by the corresponding bit in the Peripheral Power Down Registers of the System Module before accessing any FlexRay module register. For details, refer to the *Architecture* chapter and the device-specific data manual.

Copyright © 2018, Texas Instruments Incorporated

Figure 26-1. FlexRay Module Block Diagram

- Input Buffer (IBF)

  For write access to the message buffers configured in the message RAM, the CPU or the FTU can write the header and data section for a specific message buffer to the input buffer. The message handler then transfers the data from the input buffer to the selected message buffer in the message RAM.
- Output Buffer (OBF)

  For read access to a message buffer configured in the message RAM the message handler transfers the selected message buffer to the output buffer. After the transfer has completed, the CPU or the FTU can read the header and data section of the transferred message buffer from the output buffer.
- Message Handler (MHD)

  The message handler controls data transfers between the following components:
  - Input / output buffer and message RAM
  - Transient buffer RAMs of the two FlexRay protocol controllers and message RAM
- Message RAM

  The message RAM stores up to 128 FlexRay message buffers together with the related configuration data (header and data partition).
- The Transient Buffer RAM (TBF A/B):

  Stores the data section of two complete messages.

Copyright © 2018, Texas Instruments Incorporated

- FlexRay Channel Protocol Controller (PRT A/B)

  The FlexRay channel protocol controllers consist of a shift register and the FlexRay protocol FSM (Finite State Machine). They are connected to the transient buffer RAMs for intermediate message storage and to the physical layer via bus drivers (BD).

  They perform the following functionality:

  – Control and check of bit timing
  – Reception / transmission of FlexRay frames and symbols
  – Check of header CRC
  – Generation / check of frame CRC
  – Interfacing to bus driver

  The FlexRay channel protocol controllers have interfaces to:

  – Physical layer (bus driver)
  – Transient buffer RAM
  – Message handler
  – Global Time Unit
  – System universal control
  – Frame and symbol processing
  – Network management
  – Interrupt control
- Global time unit (GTU)

  The GTU performs the following functions:

  – Generation of microtick
  – Generation of macrotick
  – Fault tolerant clock synchronization by FTM algorithm
    - rate and offset correction
    - offset correction
  – Cycle counter
  – Timing control of static segment
  – Timing control of dynamic segment (minislotting)
  – Support of external clock correction
- System Universal Control (SUC)

  The SUC controls the following functions:

  – Configuration
  – Wakeup
  – Startup
  – Normal Operation
  – Passive Operation
  – Monitor Mode
- Frame and Symbol Processing (FSP)

  The frame and symbol processing controls the following functions:

  – Checks the correct timing of frames and symbols
  – Tests the syntactical and semantic correctness of received frames
  – Sets the slot status flags
- Network Management (NEM)

  Handles the network management vector.

Copyright © 2018, Texas Instruments Incorporated

- Interrupt Control (INT)
  The interrupt controller performs the following functions:
  – Provides error and status interrupt flags
  – Enable / disable interrupt sources
  – Assignment of interrupt sources to the two module interrupt lines
  – Enable / disable module interrupt lines
  – Manages the two interrupt timers
  – Stop watch time capturing
- 80-MHz Clock Signal

  NOTE: VCLKA2 is used to provide the 80-MHz clock to the FlexRay Module. The second PLL / Clock Source 6 in the microcontroller is typically used as source for VCLKA2.

  Clock signal for the sample clock (SCLK) of the FlexRay module.
- Module Clock ($VBUS_{CLK}$)
  The FlexRay module clock (BCLK) is derived from the Peripheral Clock $VBUS_{CLK}$ of the microcontroller.

26.1.3 FlexRay Module Blocks

Figure 26-2 shows the different module blocks of the FlexRay module: the communication controller, the transfer unit, and the transfer unit RAM. The RAM of the communication controller is only memory-mapped in test mode, where it is mapped to the register set address range. The address ranges of the three FlexRay blocks are shown in Table 26-1.

Figure 26-2. FlexRay Module Blocks

Copyright © 2018, Texas Instruments Incorporated

Table 26-1. FlexRay Address Range Table

Module	Address Range
FlexRay Communication Controller	0xFFF7_C800 - 0xFFF7_CFFF
FlexRay TU	0xFFF7_A000 - 0xFFF7_A1FF
FlexRay TU RAM	0xFF50_0000 - 0xFF51_FFFF

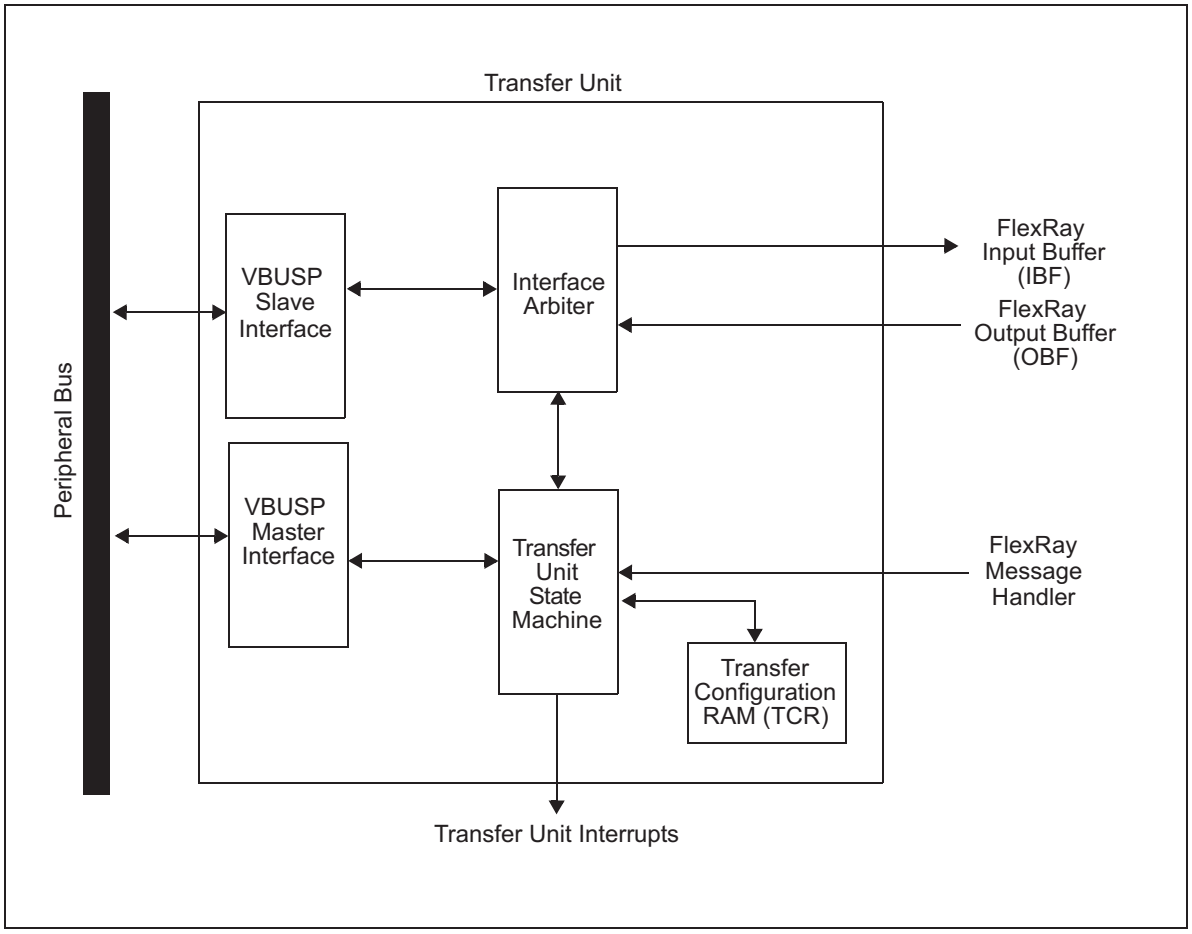
26.2 Module Operation

26.2.1 Transfer Unit

The FlexRay Transfer Unit (FTU), Figure 26-3, has an internal intelligent state-machine (Transfer Unit State Machine) to transfer data between the Input and Output Buffer Interfaces of the FlexRay core module and the system memory of the microcontroller without CPU interaction. It operates in a similar manner to a DMA (Direct Memory Access) module.

The FlexRay Input Buffer (IBF) and FlexRay Output Buffer (OBF) can also be accessed directly by the CPU. In this case the IBF and OBF are 8-, 16-, and 32-bit accessible. For transfers using the Transfer Unit State Machine only 4 × 32-bit data packages (4 word bursts) are supported.

The Interface Arbiter controls the access to the IBF and OBF. Direct CPU accesses to IBF and OBF are not possible, if the Transfer Unit State Machine is switched on. Accesses will be ignored and the associated error interrupt will be generated.



The Transfer Unit State Machine is the head of all manual, event driven and automatic message transfer activities. It controls the Transfer Unit interrupt generation related to transfer protocol correctness, status and violations of the message transfers.

With the Transfer Configuration RAM (TCR) the transfer sequence, executed by the Transfer Unit State Machine, can be configured.

The usage of the Transfer Unit allows the user to setup a mirror of the FlexRay message RAM in the fast accessible data RAM of the microcontroller. The Transfer Unit can handle the data transfers between the data RAM and the FlexRay message RAM in the ‘background’ without CPU interaction.

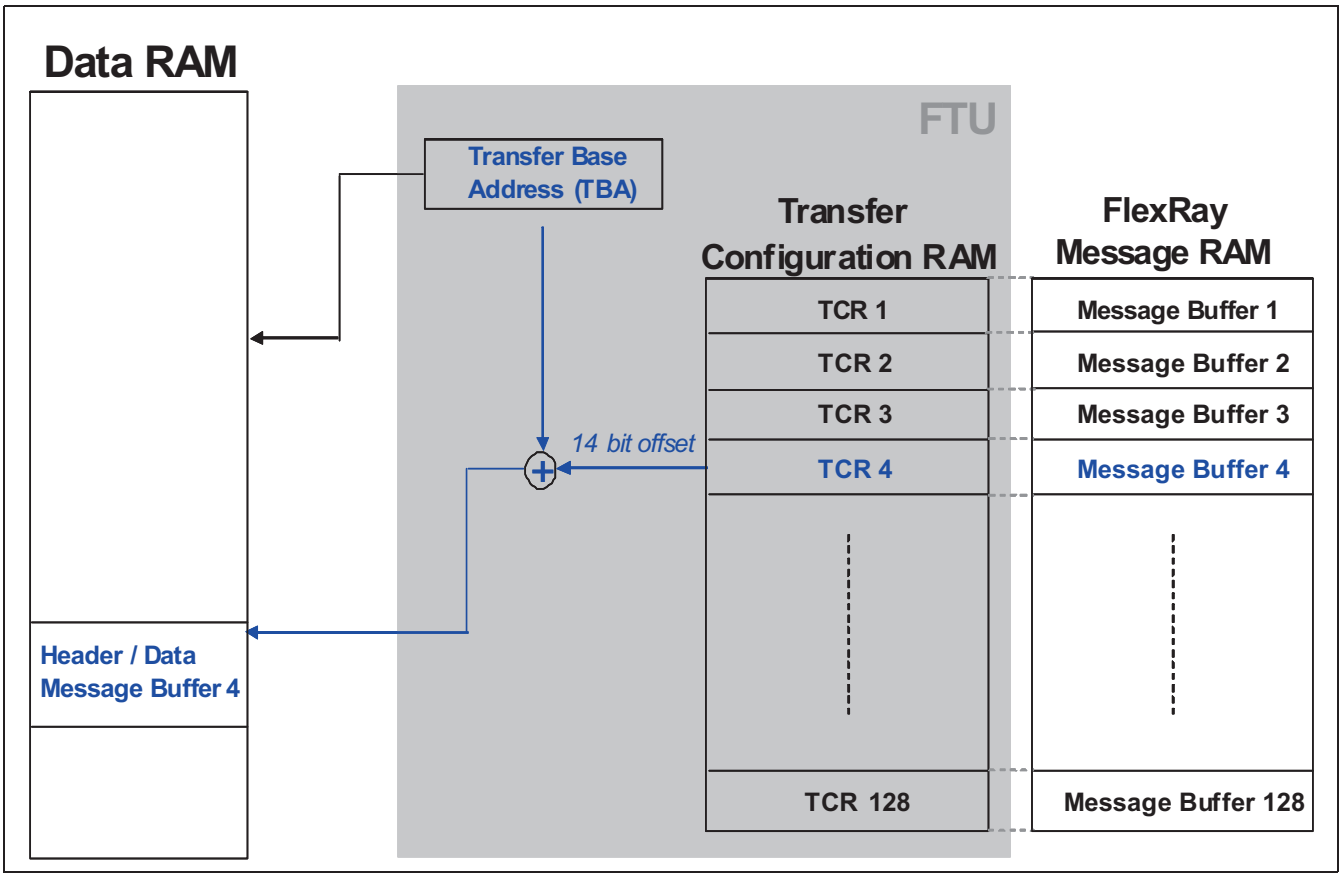
Figure 26-3. Transfer Unit

Copyright © 2018, Texas Instruments Incorporated



26.2.1.1 Transfer Unit Functional Description

Figure 26-4 shows the principle of the Transfer Unit operation.

Each FlexRay message buffer of the FlexRay message buffer RAM has one Transfer Configuration RAM (TCR) entry assigned to it, that is, message buffer 1 is assigned to TCR1, message buffer 2 is assigned to TCR2, and so on.

The Transfer Base Address (TBA) register of the Transfer Unit holds the message buffer base address in the data RAM. Each Transfer Configuration RAM (TCR) entry contains a 14 bit offset value to the dedicated message buffer area in the data RAM.

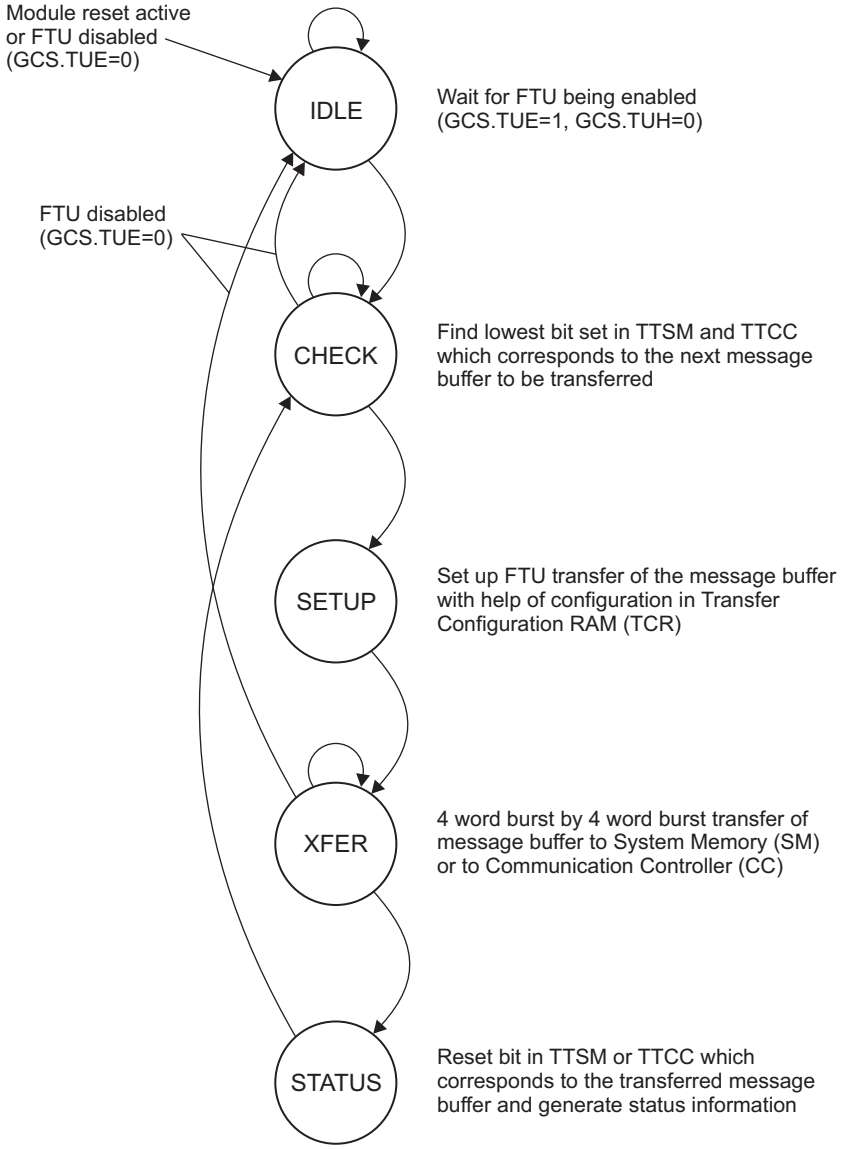


Figure 26-4. FlexRay Transfer Unit Operation Principle

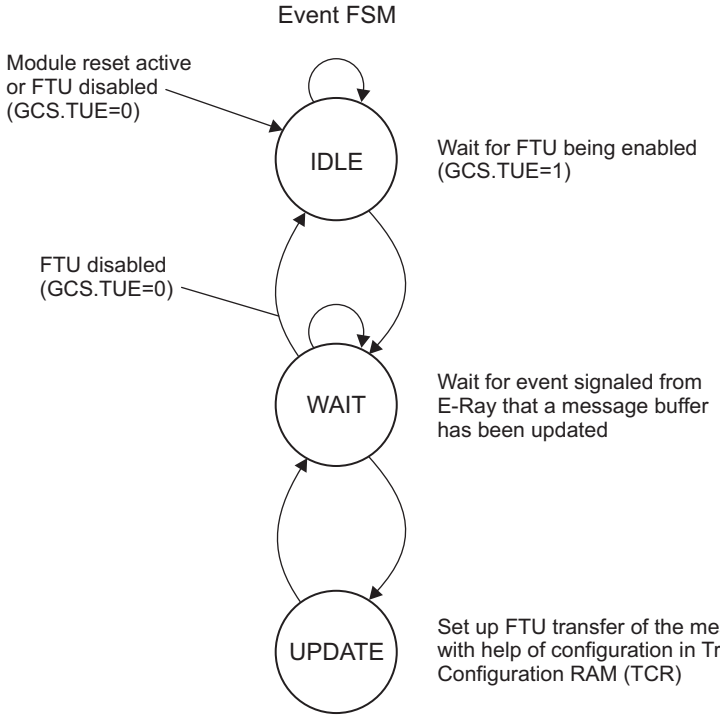
The following two diagrams show the principle of the Transfer Unit operation including Transfer State Machine (see Figure 26-5) and Event State Machine (see Figure 26-6).



Copyright © 2018, Texas Instruments Incorporated

Figure 26-5. FlexRay Transfer Unit Operation Principle for Transfer FSM (simplified)

Figure 26-6. FlexRay Transfer Unit Operation Principle for Event FSM (simplified)

ETESMS/R	CESMS/R	Set bit TTSM	Clear bit ETESMS/R
0	-	False	False
1	0	True	False
1	1	True	True

26.2.1.1.1 Transfer Control

26.2.1.1.1.1 Transfer Start and Halt

The Transfer Unit State Machine can be halted, effectively stopping the Transfer Unit transfer sequence (after completion of the current 4 word burst transfer cycle). After releasing from halt state, the Transfer Unit resumes exactly, where it was halted without data loss.

NOTE: It is the software's responsibility to ensure data coherency when the FlexRay module continues to receive data, but the Transfer Unit doesn't transfer it.

26.2.1.1.1.2 Transfer Abort

A Transfer Unit transfer will be aborted and the Transfer Unit will be disabled automatically in case of:

- an ECC multi-bit error while accessing the Transfer Configuration RAM (TCR)
- an uncorrected bit error while accessing the Transfer Configuration RAM (TCR), when ECC single-bit error correction is disabled
- a memory protection error while accessing the data RAM of the microcontroller. In this case, the ongoing transfer is aborted but the TUE bit in GCS/R may not get reset. User shall clear the TUE bit manually by software.

Copyright © 2018, Texas Instruments Incorporated

26.2.1.1.1.3 Transfer Reset

The Transfer Unit State Machine can be reset by the Transfer Unit Enable (TUE) bit in the Global Control register. Though the Transfer Unit State Machine can be reset with the above, the module register contents and the Transfer Configuration RAM (TCR). So, after re-enabling the Transfer Unit no reconfiguration of the Transfer Unit is required.

26.2.1.1.1.4 Transfer Modes

Possible transfer sequence modes are:

- Manual by triggering the desired transfer by setting the corresponding bit in the Trigger Transfer to System Memory (TTSM) register or the Trigger Transfer to Communication Controller (TTCC) register
- Event-Driven (transfers from FlexRay Communication Controller to the System Memory only) using the Enable Transfer on Event to System Memory (ETESM) register.
- Single or continuous event driven transfers by using the Clear on Event to System Memory (CESM)

The transfer event trigger in general occurs upon completion of a reception or transmission of a frame through the FlexRay bus. Table 26-2 shows more details: Conditions marked with 'X' per row must match to trigger a FTU transfer event as configured in the Transfer Configuration RAM (TCR):

Table 26-2. FlexRay Transfer Unit Event Trigger Conditions

	Event on Channel A	Event on Channel B	Frame belonging to static segment or first slot of dynamic segment	Frame belonging to dynamic segment, except first slot of dynamic segment	Bus activity detected on Channel A (MBS.ESA = 0)	Bus activity detected on Channel B (MBS.ESB = 0)
FTU Event Trigger for Receive Message Buffers	X		X			
		X	X			
	X			X	X	
		X		X		X
FTU Event Trigger for Transmit Message Buffers	X				X	
		X				X

NOTE: By setting the corresponding bit in the Enable Transfer on Event to System Memory (ETESM) register prior to an on-demand transfer to the Communication Controller by way of the Trigger Transfer to Communication Controller (TTCC) register, an event-triggered transmission back to the System Memory can be initiated, once the buffer has been sent out on the FlexRay bus. This mechanism can be used, for instance, to automatically read back the header status information to the system memory after a transmission occurred.

The transmission or reception of null frames in the static segment of a FlexRay communication cycle triggers transfers of the transfer unit. The header and/or payload is transferred to the system memory, if the corresponding bits THTSM and/or TPTSM in the Transfer Configuration RAM (TCR) are set. If neither THTSM nor TPTSM bit is set in TCR, neither header nor payload gets transferred. The corresponding bit in the Transfer to System Memory Occurred register (TSMO) gets set in all cases.

Copyright © 2018, Texas Instruments Incorporated

26.2.1.1.1.5 Transfer Size and Types

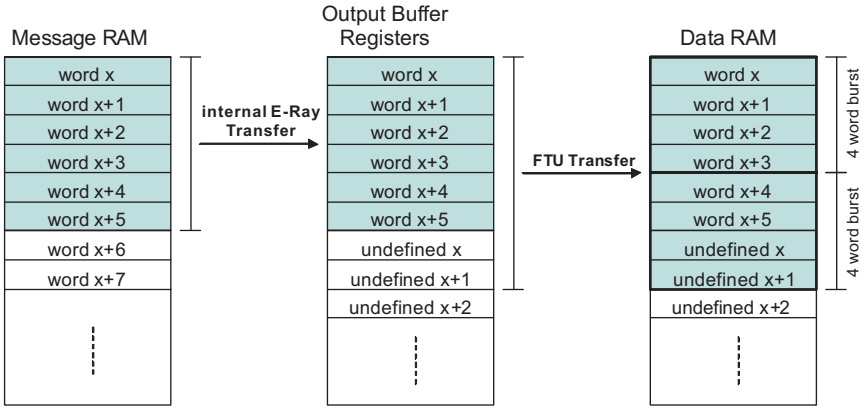
The data transferred by the Transfer Unit can be selected as:

- data and header section
- header section only
- data section only

The number of transferred payload words is derived from the Payload Length Configured (PLC) information configured in the Write Header Section 2 (WRHS2) register.

As only 4 word bursts are supported for the Transfer Unit transfers, only multiple of 4x32-bit data packets are supported. Additional transferred words are undefined, as indicated in Figure 26-7 and Figure 26-8.

Figure 26-7. Example: FTU Read Transfer of 6 Words



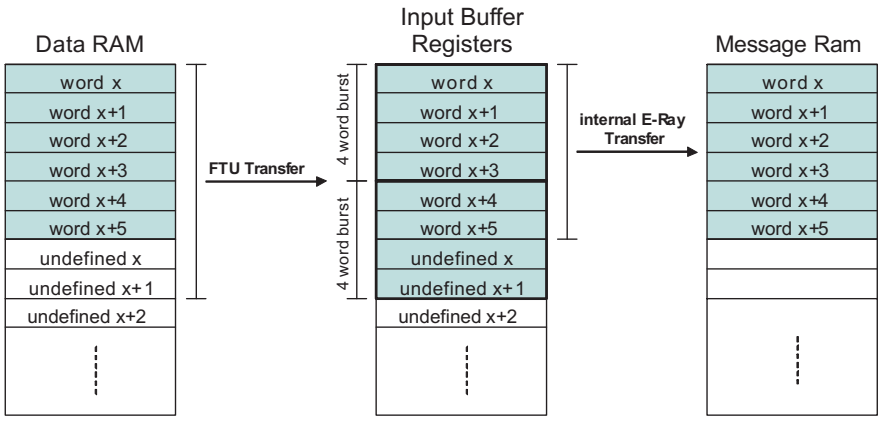


Figure 26-8. Example: FTU Write Transfer of 6 Words

Physically the FTU continues reading the additional words from the source location it started the burst transfer. Therefore, on reads, the additional transferred words depend on the contents of the Communication Controller Output Buffer Registers as indicated in Figure 26-7. On writes the additional words depend on the contents of the data RAM, as shown in Figure 26-8. The additional data will be written to the Communication Controller's Input Buffer Registers, but not transferred to the message RAM.

NOTE: It should be ensured that the allocated data RAM space for FTU transfers ends on 4x32 bit boundary to avoid possible data overwrites or memory protection issues on FTU reads and avoid reading the additional data from the source location on FTU writes.

Copyright © 2018, Texas Instruments Incorporated

26.2.1.1.1.6 Transfer Status Indication

There are 3 registers indicating the transfer status:

- Transfer Status Current Buffer (TSCB) shows the current transfer buffer status
- Last Transferred Buffer to Communication Controller (LTBCC) indicates the last completed buffer transfer to the communication controller
- Last Transferred Buffer to System Memory (LTBSM) shows the last completed buffer transfer to system memory

26.2.1.1.1.7 Transfer Mirror Function

In order to efficiently access the transfer unit status registers in the system memory, the following registers can be mirrored to the system memory starting at the base address defined in the Base Address of Mirrored Status (BAMS) register:

- Transfer Status Current Buffer (TSCB)
- Last Transferred Buffer to Communication Controller (LTBCC)
- Last Transferred Buffer to System Memory (LTBSM)
- Transfer to System Memory Occurred 1/2/3/4 (TSMO1-4)
- Transfer to Communication Controller Occurred 1/2/3/4 (TCCO1-4)
- Transfer Occurred OFFset (TOOFF)

The mirrored values are updated after completion of a buffer transfer.

The mirroring of these registers can be disabled if not needed.

Table 26-3. Mirroring Address Mapping

Address	Register
BAMS+0x00	TSCB
BAMS+0x04	LTBCC
BAMS+0x08	LTBSM
BAMS+0x0C	TSMO1
BAMS+0x10	TSMO2
BAMS+0x14	TSMO3
BAMS+0x18	TSMO4
BAMS+0x1C	TCCO1
BAMS+0x20	TCCO2
BAMS+0x24	TCCO3
BAMS+0x28	TCCO4
BAMS+0x2C	TOOFF

26.2.1.1.1.8 Endianness Correction

For the data transfer by the Transfer Unit an Endianness correction mechanism can be used to switch big Endianness data to little Endianness data and vice versa.

For maximum flexibility, 6 bits are available in the Global Control Set/Reset Register (GCS/R) to control.

- Header Data byte-order
- Payload Data byte-order
- Byte-order of the FlexRay Core registers and the Transfer Configuration RAM data of the Transfer Unit

independently and in both directions.

Copyright © 2018, Texas Instruments Incorporated

26.2.1.1.1.9 Transfer Data Package

Table 26-4 shows the data of a transfer data package. Independent of whether the header gets transferred or not, the buffer address always points to element Header1.

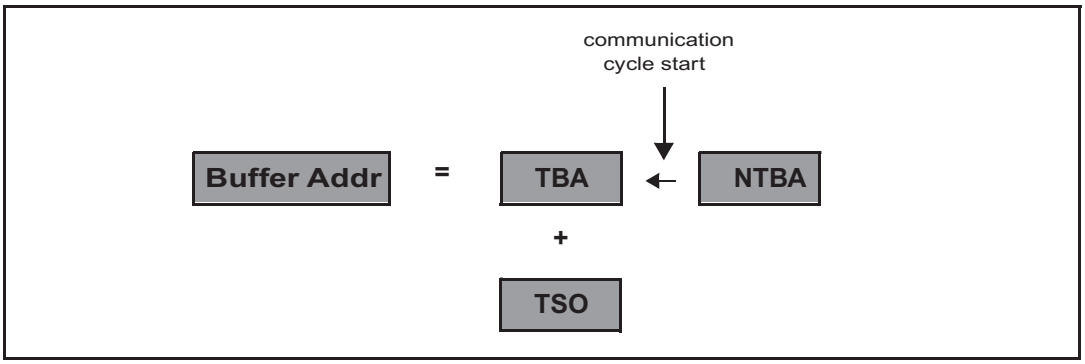
Table 26-4. Mirroring Address Mapping

Address	Register
0x0000	Header1
0x0004	Header2
0x0008	Header3
0x000C	Buffer Status(1)
0x0010	Payload1
0x0014	Payload2
:	:
0x010C	Payload64

(1) Transferred only from Communication Controller to System Memory

26.2.1.1.1.10 Transfer Start Address to Message Buffer Number Assignment

The assignment of a FlexRay message buffer number to the transfer location in system memory is done by the combination of:



- the Transfer Start Offset (TSO) field in a Transfer Configuration RAM (TCR) entry
- the Transfer Base Address (TBA) register

Each entry of the TCR holds a 14 bit offset value (TSO). The TSO offset will be added to the content of the TBA register. The TBA register holds the 32bit base address-pointer to a location of the data RAM.

A value written to Next Transfer Base Address (NTBA) will be loaded in the TBA at the next communication cycle start. This allows efficient multi-buffering of the message buffers in the system memory. The Transfer Not Ready (NTR) flag in the Transfer Error Interrupt Flag (TEIF) register can be used to determine, if NTBA can be reloaded by the CPU.

NOTE: If a value is written to TBA, NTBA is set to the same value.

Figure 26-9. Transfer Start Address to Message Buffer Number Assignment

26.2.1.1.1.11 Transfer Priority

The Transfer Unit will transfer the message buffers from low to high message buffer numbers.

In case the same buffer is pending in both the Trigger Transfer to Communication (TTCC) register and the Trigger Transfer to System Memory (TTSM) register, the priority between TTCC and TTSM is determined by the Transfer Priority bit (GC.PRIO) in the Transfer Unit Global Control Set/Reset Register (GCS/R).

Copyright © 2018, Texas Instruments Incorporated

26.2.1.1.1.12 Read Transfers

A read transfer is the data transfer from FlexRay message buffer RAM to the system memory of the microcontroller.

For read transfers the registers Trigger Transfer to System Memory (TTSM), Enable Transfer on Event to System Memory (ETESM) and Clear on Event to System Memory (CESM) have to be setup.

The amount and type of data to be transferred can be selected as:

- data and header section
- header section only
- data section only

which can be configured on the Transmit Configuration RAM (TCR).

The number of 32 bit words per buffer to be transferred is read from the Payload Length Configured (RDHS2.PLC) configuration information. This information is part of the header section stored in the message RAM of the Communication Controller.

26.2.1.1.1.13 Write Transfers

A write transfer is the data transfer from the system memory of the microcontroller to the FlexRay message buffer RAM.

For write transfers the Trigger Transfer to Communication (TTCC) register has to be setup.

The amount and type of data transferred can be selected as:

- data and header section
- header section only
- data section only

which can be configured on the Transmit Configuration RAM (TCR).

It can be configured in the TCR, if Set Transmission Request Host (STXRH) bit in the Input Buffer Command Mask (IBCM) of the Communication Controller should be set. This would trigger the transfer to the FlexRay bus.

If a data and header section transfer is selected, the number of 32 bit words to be transferred is read from the Payload Length Configured (PLC) configuration information stored in Header2 word in the system memory.

If a data section only transfer is selected, the number of 32 bit words to be transferred is read from the Payload Length Configured (RDHS2.PLC) configuration information. This information is part of the header section stored in the message RAM of the Communication Controller.

26.2.1.1.1.14 Transfer Unit Event Interface

The Transfer Unit Event Control generates transfer trigger signals for transfers in the following cases:

- For transmit (TX) message buffers, a write transfer trigger is generated, if a transmit event occurs. The configured TX message buffers generate a transfer trigger, except when a Nullframe in static segment or no frame in the dynamic segment is sent.
- For receive (RX) message buffers, a read transfer trigger is generated, if a receive event occurs in the static segment.
- For receive (RX) message buffers, a read transfer trigger is generated if a receive event occurs in the dynamic segment, updated in the current cycle and no Nullframe.

If a buffer is part of the FIFO, no transfer trigger is generated!

When the Transfer Unit is disabled (TUE bit in Global Control Register (GCS/R) is 0), no transfer trigger is generated, whereas if the Transfer Unit is enabled, but in halt mode (TUH bit and TUE bit in Global Control Register (GCS/R) are 1), the occurring triggers remain pending and get executed when the Transfer Unit will be resumed from halt mode.

Copyright © 2018, Texas Instruments Incorporated

26.2.1.1.2 Transfer Configuration RAM

The Transfer Configuration RAM (TCR) consists of 128 entries, one entry for each possible FlexRay buffer. Entry 1 is assigned to FlexRay buffer 1, entry 2 to FlexRay buffer 2,..., and entry 128 is assigned to FlexRay buffer 128.

Each TCR entry defines:

- data transfer size (header + data, header only or data only)
- whether the transmit request flag (STRXH) should be set for the data transferred by the FTU to the CC to send out the data to the FlexRay bus.
- the 14-bit buffer address offset, which, in combination with the Transfer Base Address defined in TBA, specifies the start of the corresponding FlexRay message buffer in the system memory RAM.

NOTE: It is recommended to clear the whole TCR before configuring it, in order to avoid unexpected transfer behavior due to old configuration contents or random TCR RAM contents after power on reset.

If a transfer is triggered but no transfer size (header or data) is setup in the TCR, no data will be transferred, but the corresponding flag in the Transfer to Communication Controller Occurred (TCCOx) or the Transfer to System Memory Occurred (TSMOx) will be set.

26.2.1.1.2.1 ECC Protection

The Transfer Configuration RAM (TCR) is ECC protected. The ECC multi-bit error interrupt generation is disabled by default and can be switched on by writing a 4 bit key to dedicated ECC lock bits in the Global Control Set/Reset Register (GCS/R).

The ECC protection supports single-bit error correction and double-bit error detection mechanism (SECDED). The ECC information is stored together with the corresponding 19-bit data word entry.

The ECC is checked each time a data word is read from the TCR RAM. If an ECC error is detected, the PE error flag is set in the Transfer Error Interrupt Flag (TEIF) register. The detection of an ECC single-bit error will be indicated by the SE flag in the TCR Single-Bit Error Status (TSBESTAT).

Additionally an uncorrectable RAM error interrupt/event will be generated. The uncorrectable RAM error interrupt/event is non maskable and therefore cannot be switched off. For ECC single-bit errors, the uncorrectable RAM error interrupt/event is generated, if the ECC single-bit error correction is disabled. The uncorrectable RAM error is hooked up to the ESM module (event).

The faulty TCR RAM address can be read from the ECC Error Address (PEADR) register. Equivalent information is available for ECC single-bit errors in the TCR Single-Bit Error Status (TSBESTAT) register. Independent of the ECC single-bit error correction being enabled or disabled, the TSBESTAT is updated. See Figure 26-26 for more details.

26.2.1.1.3 Memory Protection Mechanism

This feature allows to restrict accesses to certain areas in memory in order to protect critical application data from unintentionally being accessed by the Transfer Unit State Machine.

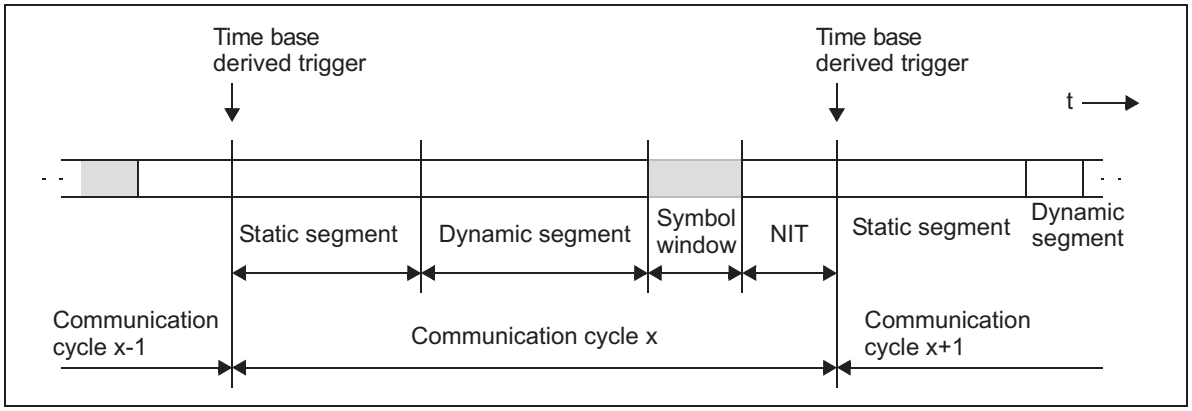
One memory section (start and end address) can be defined, which allows read and write accesses for the Transfer Unit State Machine.

If the end address is smaller or equal to the start address, data transfers will be blocked. Any accesses performed outside this memory area by the Transfer Unit State Machine result in no transfers being performed. In case of a protection violation a flag will be set and the Memory Protection Violation interrupt will be activated. The Transfer Unit State Machine will be disabled in this case.

The default setting of the Transfer Unit State Machine memory protection address range setup is 0x00000000 for start address and 0x00000000 for end address.

This means a valid address range must be setup, before the Transfer Unit can be used.

Copyright © 2018, Texas Instruments Incorporated



26.2.2 Communication Cycle

A communication cycle in FlexRay (Figure 26-10) consists of the following elements:

- Static segment
- Dynamic segment
- Symbol window
- Network idle time (NIT)

Static segment, dynamic segment, and symbol window form the network communication time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized macrotick.

Figure 26-10. Structure of Communication Cycle

26.2.2.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of frame transmission at action point of the corresponding static slot
- Payload length same for all frames on both channels

Parameters: number of static slots GTUC7.NSS(9-0), static slot length GTUC7.SSL(9-0), Payload Length Static MHDC.SFDL(6-0), action point offset GTUC9.APO(5-0)

26.2.2.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters: number of minislots GTUC8.NMS(12-0), minislot length GTUC8.MSL(5-0), minislot action point offset GTUC9.MAPO(4-0), start of latest transmit (last minislot) MHDC.SLT(12-0)

26.2.2.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are sent in NORMAL_ACTIVE state to test the bus guardian.

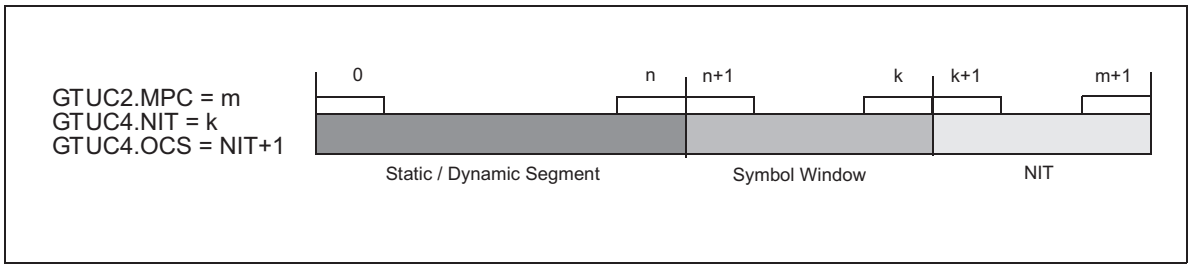
The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Copyright © 2018, Texas Instruments Incorporated

Parameters: Symbol Window Action Point Offset GTUC9.APO(4-0) (same as for static slots), Network Idle Time Start GTUC4.NIT(13-0)

26.2.2.4 Network Idle Time (NIT)



During network idle time the communication controller has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple macroticks after offset correction start
- Perform cluster cycle related tasks

Parameters: network idle time start GTUC4.NIT(13-0), offset correction start GTUC4.OCS(13-0)

26.2.2.5 Configuration of NIT Start and Offset Correction Start

Figure 26-11. Configuration of NIT Start and Offset Correction Start

The number of macroticks per cycle is assumed to be m. It is configured by programming GTUC2.MPC = m in the GTU Configuration register 2.

The static / dynamic segment starts with macrotick 0 and ends with macrotick n: n = static segment length + dynamic segment offset + dynamic segment length - 1MT

The static segment length is configured by GTUC7.SSL and GTUC7.NSS. The dynamic segment length is configured by GTUC8.MSL and GTUC8.NMS.

The dynamic segment offset is ActionPointOffset - MinislotActionPointOffset or 0 MT if the result is negative. For details, refer to the FlexRay Communications System Protocol Specification from the FlexRay Consortium.

The NIT starts with macrotick k+1 and ends with the last macrotick of cycle m-1. It has to be configured by setting GTUC4.NIT = k.

For this FlexRay module the offset correction start is required to be GTUC4.OCS >= GTUC4.NIT + 1 = k+1.

The length of symbol window results from the number of macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by k - n.

26.2.3 Communication Modes

The FlexRay protocol specification v2.1 Rev. A defines the Time-Triggered Distributed (TT-D) mode.

26.2.3.1 Time-Triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- Pure static: minimum 2 static slots + symbol window (optional)
- Mixed static/dynamic: minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes need to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each startup frame must be a sync frame, therefore all coldstart nodes are sync nodes.

Copyright © 2018, Texas Instruments Incorporated

26.2.4 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received sync frames from other nodes.

26.2.4.1 Global Time

Activities in a FlexRay node, including communication, are based on the concept of a global time, even though each individual node maintains its own view of it. It is the clock synchronization mechanism that differentiates the FlexRay cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (macrotick counter).

Cluster specific:

- Macrotick (MT) = basic unit of time measurement in a FlexRay network, a macrotick consists of an integer number of microticks (μT)
- Cycle length = duration of a communication cycle in units of macroticks (MT)

26.2.4.2 Local Time

Internally, nodes time their behavior with microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore microticks are controller-specific units. They may have different duration in different controllers. The precision of a nodes local time difference measurements is a microtick (μT).

Node specific:

- Sample clock -> prescaler -> microtick (μT); typically 25ns.
- μT = basic unit of time measurement in a communication controller, clock correction is done in units of μTs
- Cycle counter + macrotick counter = nodes local view of the global time

26.2.4.3 Synchronization Process

Clock synchronization is performed by means of sync frames. Only preconfigured nodes (sync nodes) are allowed to send sync frames. In a two-channel cluster, a sync node has to send its sync frame on both channels.

For synchronization in FlexRay the following constraints have to be considered:

- Max. one sync frame per node in one communication cycle
- Max. 15 sync frames per cluster in one communication cycle
- Every node has to use a preconfigured number of sync frames (GTUC2.SNM(3-0)) for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of sync frames received during the static segment is measured. In a two channel cluster the sync node has to be configured to send sync frames on both channels. The calculation of correction terms is done during NIT (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay protocol specification v2.1 Rev. A.

26.2.4.3.1 Offset (Phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during NIT of every communication cycle
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values
- Correction value is a signed integer number of μTs

Copyright © 2018, Texas Instruments Incorporated

- Correction done in odd numbered cycles, distributed over the macroticks beginning at offset correction start up to cycle end (end of NIT) to shift nodes next start of cycle (MTs lengthened / shortened)

26.2.4.3.2 Rate (Frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during NIT of odd numbered cycles
- Cluster drift damping is performed using global damping value
- Checked against limit values
- Correction value is a signed integer number of μTs
- Distributed over macroticks comprising the next even/odd cycle pair (MTs lengthened / shortened)

26.2.4.4 Sync Frame Transmission

Sync frame transmission is only possible from buffer 0 and 1. Message buffer 1 may be used for sync frame transmission in case that sync frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1.

Message buffers used for sync frame transmission have to be configured with the key slot ID and can be (re)configured in DEFAULT_CONFIG or CONFIG state only. For nodes transmitting sync frames SUCC1.TXSY must be set to 1.

26.2.4.5 External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

26.2.5 Error Handling

The implemented error handling concept of the FlexRay protocol is intended to ensure that in the presence of a lower layer protocol error in a single node, communication between non-affected nodes can be maintained. In some cases, higher layer program command activity is required for the communication controller to resume normal operation. A change of the error handling state will set bit EIR.PEMC and can trigger an interrupt to the host if enabled. The current error mode is signaled by CCEV.ERRM(1-0).

Table 26-5. Error Modes of the POC (Degradation Model)

Error Mode	Activity
ACTIVE	**Full operation**, State: NORMAL_ACTIVE The communication controller is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status flags from registers EIR and SIR.
PASSIVE	**Reduced operation**, State: NORMAL_PASSIVE, communication controller self rescue allowed The communication controller stops transmitting frames and symbols, but received frames are still processed. Clock synchronization mechanisms are continued based on received frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status flags from registers EIR and SIR.
COMM_HALT	**Operation halted**, State: HALT, communication controller self rescue not allowed The communication controller stops frame and symbol processing, clock synchronization processing, and the macrotick generation. The host has still access to error and status information by reading the error and status flags from registers EIR and SIR. The bus drivers are disabled.

Copyright © 2018, Texas Instruments Incorporated

26.2.5.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the “maximum without clock correction passive” limit defined by SUCC3.WCP(3-0), the POC transits from NORMAL_ACTIVE to NORMAL_PASSIVE state. When it reaches the “maximum without clock correction fatal” limit defined by SUCC3.WCF(3-0), it transits NORMAL_ACTIVE or NORMAL_PASSIVE to the HALT state.

The Clock Correction Failed Counter CCEV.CCFC(3-0) allows the host to monitor the duration of the inability of a node to compute clock correction terms after the communication controller passed protocol startup phase. It will be incremented by 1 at the end of any odd numbered communication cycle where either the Missing Offset Correction flag SFS.MOCS or the Missing Rate Correction flag SFS.MRCS is set.

The clock correction failed counter is reset to 0 at the end of an odd communication cycle if neither the Missing Offset Correction flag SFS.MOCS nor the Missing Rate Correction flag SFS.MRCS is set.

The Clock Correction Failed Counter stops incrementing when the “maximum without clock correction fatal” value SUCC3.WCF(3-0) is reached (incrementing the counter at its maximum value will not cause it to wraparound back to 0). The clock correction failed counter will be initialized to 0 when the communication controller enters READY state or when NORMAL_ACTIVE state is entered.

NOTE: The transition to HALT state is prevented if SUCC1.HCSE is not set.

26.2.5.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from NORMAL_PASSIVE to NORMAL_ACTIVE state. SUCC1.SUCC1.PTA(4-0) defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the communication controller is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state. If SUCC1.PTA(4-0) is cleared to 0, the communication controller is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

26.2.5.3 HALT Command

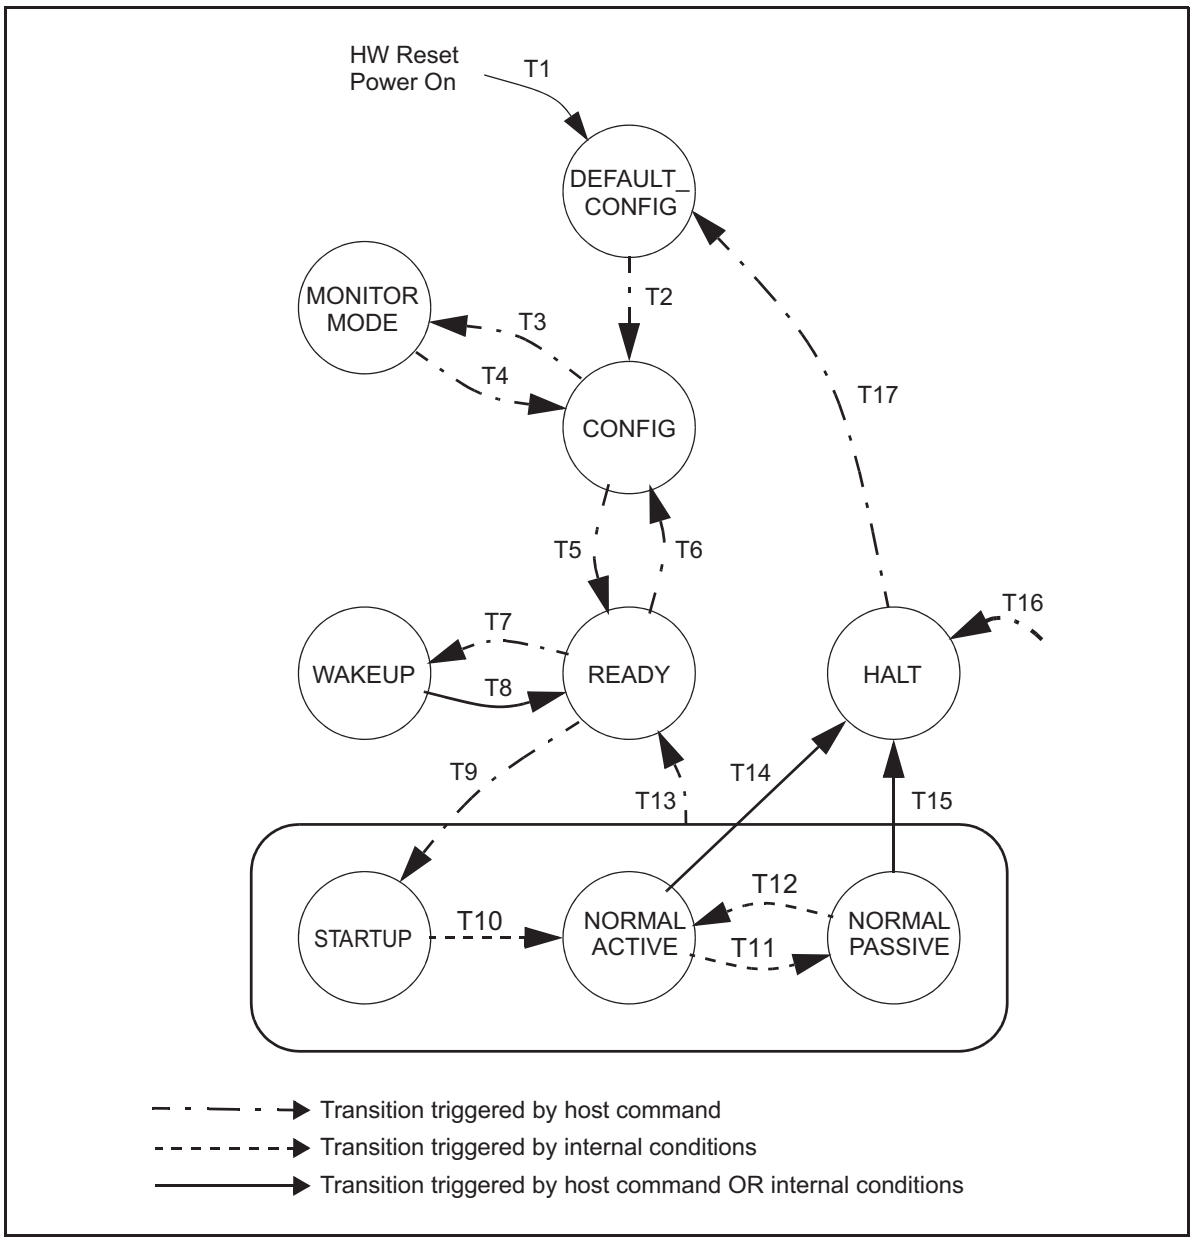
In case the host wants to stop FlexRay communication of the local node it can bring the communication controller into HALT state by asserting the HALT command. This can be done by writing SUCC1.CMD(3-0) = 0110. In order to shut down communication on an entire FlexRay network, a higher layer protocol is required to assure that all nodes apply the HALT command at the same time.

The POC state from which the transition to HALT state took place can be read from CCSV.PSL(5-0).

When called in NORMAL_ACTIVE or NORMAL_PASSIVE state the POC transits to HALT state at the end of the current cycle. When called in any other state SUCC1.CMD(3-0) will be reset to 0000 = “command_not_accepted” and bit EIR.CNA in the error interrupt register is set to 1. If enabled an interrupt to the host is generated.

26.2.5.4 FREEZE Command

In case the host detects a severe error condition it can bring the communication controller into HALT state by asserting the FREEZE command. This can be done by writing SUCC1.CMD(3-0) = 0111. The FREEZE command triggers the entry of the HALT state immediately regardless of the current POC state.



The POC state from which the transition to HALT state took place can be read from CCSV.PSL(5-0).

26.2.6 Communication Controller States

26.2.6.1 Communication Controller State Diagram

Figure 26-12. Overall State Diagram of Communication Controller

State transitions are controlled by the reset and FlexRay receive (rxd1, 2) pins, the POC state machine, and by the CHI command vector SUCC1.CMD(3-0).

The Communication Controller exits from all states to HALT state after application of the FREEZE command (SUCC1.CMD(3-0) = 0111b).

15	Clock Correction Failed counter reached “maximum without clock correction fatal” limit configured by SUCC3.WCF(3-0) AND bit SUCC1.HCSE set to 1 OR command HALT, SUCC1.CMD(3-0) = 0110	NORMAL_PASSIVE	HALT
16	Command FREEZE, SUCC1.CMD(3-0) = 0111	All States	HALT
17	Command CONFIG, SUCC1.CMD(3-0) = 0001	HALT	DEFAULT_CONFIG

26.2.6.2 DEFAULT_CONFIG State

In DEFAULT_CONFIG state, the communication controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The communication controller enters this state:

- When leaving hardware reset
- When exiting from HALT state

To leave DEFAULT_CONFIG state the host has to write SUCC1.CMD(3-0) = 0001. The communication controller then transits to CONFIG state.

26.2.6.3 CONFIG State

In CONFIG state, the communication controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the communication controller configuration.

The communication controller enters this state:

- When exiting from DEFAULT_CONFIG state
- When exiting from MONITOR_MODE or READY state

When the state has been entered by HALT and DEFAULT_CONFIG state, the host can analyze status information and configuration. Before leaving CONFIG state the host has to assure that the configuration is fault-free.

Copyright © 2018, Texas Instruments Incorporated

To leave CONFIG state, the host has to perform the unlock sequence. Directly after unlocking the CONFIG state the host has to write SUCC1.CMD(3-0) to enter the next state.

NOTE: The message buffer status registers (MHDS, TXRQ1/2/3/4, NDAT1/2/3/4, MBSC1/2/3/4) and status data stored in the message RAM and are not affected by the transition of the POC from CONFIG to READY state.

When the communication controller is in CONFIG state it is also possible to bring the communication controller into a power saving mode by halting the module clocks. To do this the host has to assure that all Message RAM transfers have finished before turning off the clocks.

26.2.6.4 MONITOR_MODE

After unlocking CONFIG state and writing SUCC1.CMD(3-0) = 1011 the communication controller enters MONITOR_MODE. In this mode the communication controller is able to receive FlexRay frames and to detect wakeup pattern. The temporal integrity of received frames is not checked, and therefore cycle counter filtering is not supported. This mode can be used for debugging purposes in case e.g. that startup of a FlexRay network fails. After writing SUCC1.CMD(3-0) = 0001 the communication controller transits back to CONFIG state.

In MONITOR_MODE the pick first valid mechanism is disabled. This means that a receive message buffer may only be configured to receive on one channel. Received frames are stored into message buffers according to frame ID and receive channel. Null frames are handled like data frames. After frame reception only status bits MBS.VFRA, MBS.VFRB, MBS.MLST, MBS.RCIS, MBS.SFIS, MBS.SYNS, MBS.NFIS, MBS.PPIS, MBS.RESS have valid values.

In MONITOR_MODE the communication controller is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags SIR.MTSA/SIR.MTSB are set. SIR.CAS has no function in MONITOR_MODE.

26.2.6.5 READY State

After unlocking CONFIG state and writing SUCC1.CMD(3-0) = 0010 the communication controller enters READY state. From this state the communication controller can transit to WAKEUP state and perform a cluster wakeup or to STARTUP state to perform a coldstart or to integrate into a running cluster.

The communication controller enters this state:

- When exiting from CONFIG, WAKEUP, STARTUP, NORMAL_ACTIVE, or NORMAL_PASSIVE state by writing SUCC1.CMD(3-0) = 0010 (READY command).

The communication controller exits from this state:

- To CONFIG state by writing SUCC1.CMD(3-0) = 0001 (CONFIG command)
- To WAKEUP state by writing SUCC1.CMD(3-0) = 0011 (WAKEUP command)
- To STARTUP state by writing SUCC1.CMD(3-0) = 0100 (RUN command)

Internal counters and the communication controller status flags are reset when the communication controller enters STARTUP state.

NOTE: Status bits MHDS(14-0), registers TXRQ1/2/3/4, and status data stored in the Message RAM are not affected by the transition of the POC from READY to STARTUP state.

Copyright © 2018, Texas Instruments Incorporated

26.2.6.6 WAKEUP State

The following description is intended to help configuring wakeup for the FlexRay module. A detailed description of the wakeup procedure can be found in the FlexRay protocol specification v2.1 Rev. A.

The communication controller enters this state:

- When exiting from READY state by writing SUCC1.CMD(3-0) = 0011 (WAKEUP command).

The communication controller exits from this state to READY state:

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a frame header
- By writing SUCC1.CMD(3-0) = 0010 (READY command)

The communication controller exits from this state to HALT state:

- By writing SUCC1.CMD(3-0) = 0111 (FREEZE command)

The cluster wakeup must precede the communication startup in order to ensure that all nodes in a cluster are awake. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an external wakeup source.

The host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the communication controller and configures bus guardian (if available) and communication controller to perform the cluster wakeup. The communication controller provides to the host the ability to transmit a special wakeup pattern on each of its available channels separately. The communication controller needs to recognize the wakeup pattern only during wakeup and startup phase.

Wakeup may be performed on only one channel at a time. The host has to configure the wakeup channel while the communication controller is in CONFIG state by writing bit WUCS in the SUC configuration register 1. The communication controller ensures that ongoing communication on this channel is not disturbed. The communication controller cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the communication controller returns to READY state and signals the change of the wakeup status to the host by setting bit SIR.WST in the status interrupt register. The wakeup status vector CCSV.WSV(2-0) can be read from the communication controller status vector register. If a valid wakeup pattern was received also either bit SIR.WUPA or bit SIR.WUPB in the status interrupt register is set.

Figure 26-13. Structure of POC State WAKEUP

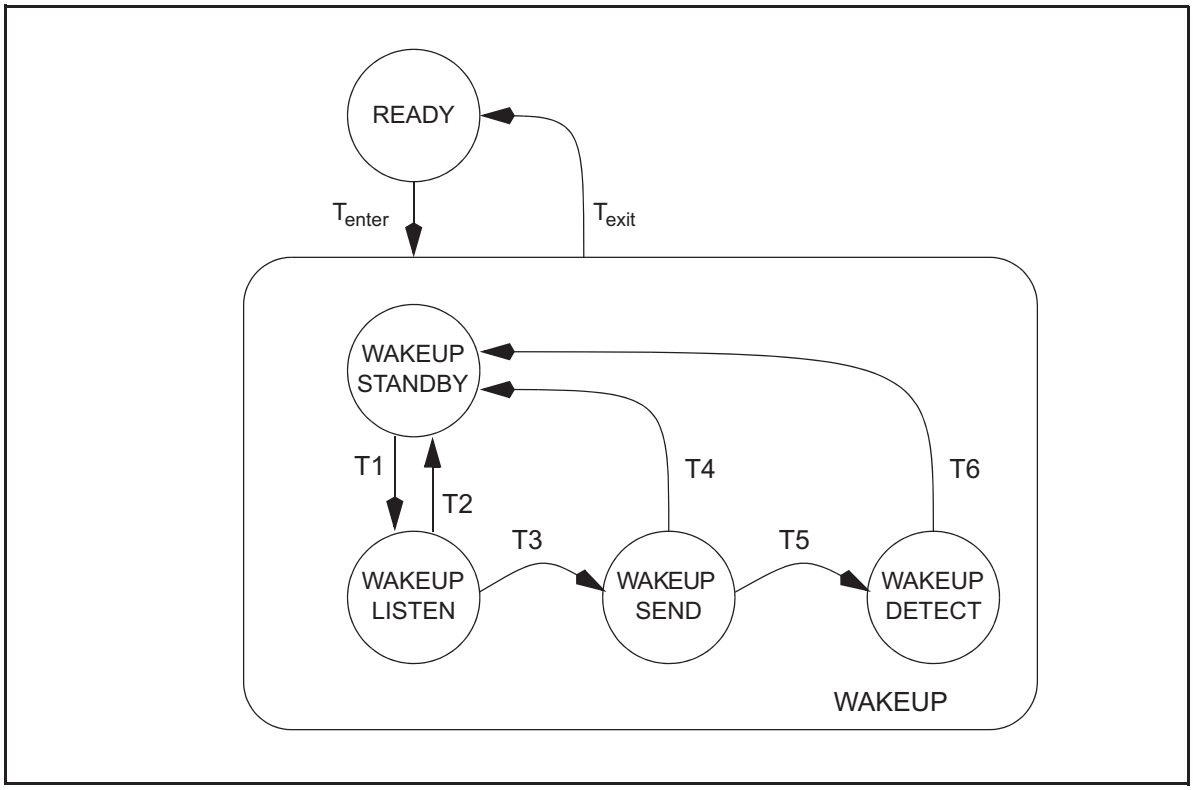

Table 26-7. State Transitions WAKEUP

T#	Condition	From	To
enter	Host commands change to WAKEUP state by writing SUCC1.CMD(3-0) = 0011 (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to WAKEUP_LISTEN state	WAKEUP_STANDBY	WAKEUP_LISTEN
2	Received WUP on wakeup channel selected by bit SUCC1.WUCS OR frame header on either available channel	WAKEUP_LISTEN	WAKEUP_STANDBY
3	Timer event	WAKEUP_LISTEN	WAKEUP_SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_SEND	WAKEUP_STANDBY
5	Collision detected	WAKEUP_SEND	WAKEUP_DETECT
6	Wakeup timer expired OR WUP detected on wakeup channel selected by bit SUCC1.WUCS OR frame header received on either available channel	WAKEUP_DETECT	WAKEUP_STANDBY
exit	Wakeup completed (after T2 or T4 or T6) OR host commands change to READY state by writing SUCC1.CMD(3-0) = 0010 (READY command). This command also resets the wakeup FSM to WAKEUP_STANDBY state.	WAKEUP	READY

The WAKEUP_LISTEN state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters Listen Timeout SUCC2.LT(20-0) and Listen Timeout Noise SUCC2.LTN(3-0). Listen timeout enables a fast cluster wakeup in case of a noise free environment, while listen timeout noise enables wakeup under more difficult conditions regarding noise interference.

Copyright © 2018, Texas Instruments Incorporated

In WAKEUP_SEND state the communication controller transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the host has to bring the communication controller into STARTUP state by CHI command RUN.

In WAKEUP_DETECT state the communication controller attempts to identify the reason for the wakeup collision detected in WAKEUP_SEND state. The monitoring is bounded by the expiration of listen timeout as configured by SUCC2.LT(20-0) in the SUC configuration register 2. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a frame header indication existing communication, causes the direct transition to READY state. Otherwise WAKEUP_DETECT is left after expiration of listen timeout; in this case the reason for wakeup collision is unknown.

The host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay Protocol Specification recommends that two different communication controllers shall wake the two channels.

26.2.6.6.1 Host Activities

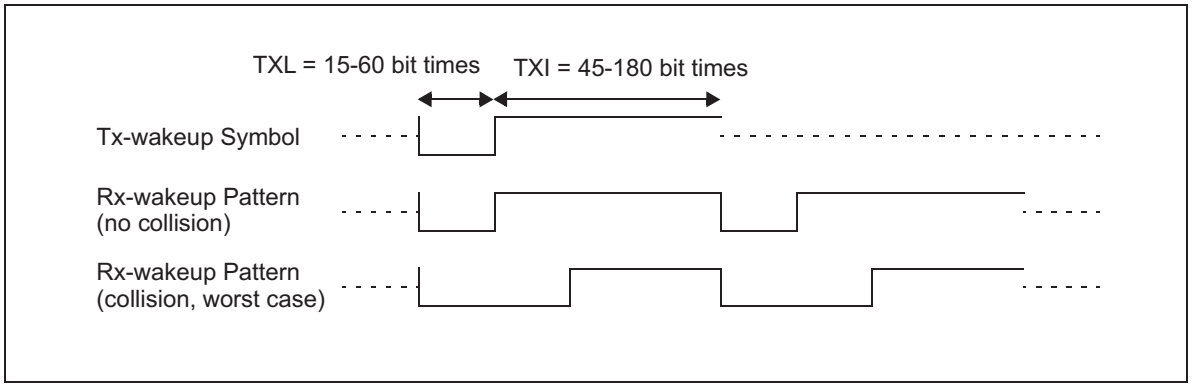
The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the host. The wakeup pattern is detected by the remote BDs and signaled to their local hosts.

Wakeup procedure controlled by host (single-channel wakeup):

- Configure the communication controller in CONFIG state
  - Select wakeup channel by programming bit SUCC1.WUCS
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command communication controller to enter READY state
- Command communication controller to start wakeup on the configured channel by writing SUCC1.CMD(3-0) = 0011
  - communication controller enters WAKEUP_LISTEN
  - communication controller returns to READY state and signals status of wakeup attempt to host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node:
  - in dual channel cluster wait for WUP on the other channel
  - Reset Coldstart Inhibit flag CCSV.CSI by writing SUCC1.CMD(3-0) = 1001 (ALLOW_COLDSTART command)
- Command communication controller to enter startup by writing SUCC1.CMD(3-0) = 0100 (RUN command)

Wakeup procedure triggered by the bus driver:

- Wakeup recognized by bus driver
- bus driver triggers power-up of host (if required)
- bus driver signals wakeup event to host
- Host configures its local communication controller
- If necessary host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands communication controller to enter STARTUP state by writing SUCC1.CMD(3-0) = 0100 (RUN command)



Copyright © 2018, Texas Instruments Incorporated

26.2.6.6.2 Wake Up Pattern (WUP)

The wake up pattern (WUP) is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by the PRT configuration registers 1,2.

- Single channel wakeup, wake up symbol may not be sent on both channels at the same time
- Wakeup symbol collision resilient for up to two sending nodes (two overlapping wakeup symbols still recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by PRTC2.TXL(5-0)
- Wakeup symbol idle time configured by PRTC2.TXI(7-0), used to listen for activity on the bus
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by PRTC1.RWP(5-0) (2 to 63 repetitions)
- Wakeup symbol receive window length configured by PRTC1.RXW(8-0)
- Wakeup symbol receive low time configured by PRTC2.RXL(5-0)
- Wakeup symbol receive idle time configured by PRTC2.RXI(5-0)

Figure 26-14. Timing of Wake Up Pattern

26.2.6.7 STARTUP State

The following description is intended to help configuring startup for the FlexRay module. A detailed description of the startup procedure can be found in the FlexRay protocol specification v2.1 Rev. A.

Any node entering STARTUP state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup frames. Startup frames are both sync frames and null frames during startup.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter NORMAL_ACTIVE state by:

- Coldstart path initiating the schedule synchronization (leading coldstart node)
- Coldstart path joining other coldstart nodes (following coldstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

See also Figure 26-15 for more information.

Copyright © 2018, Texas Instruments Incorporated

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that transmitted the CAS, transmits frames in the first four cycles after the CAS. it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

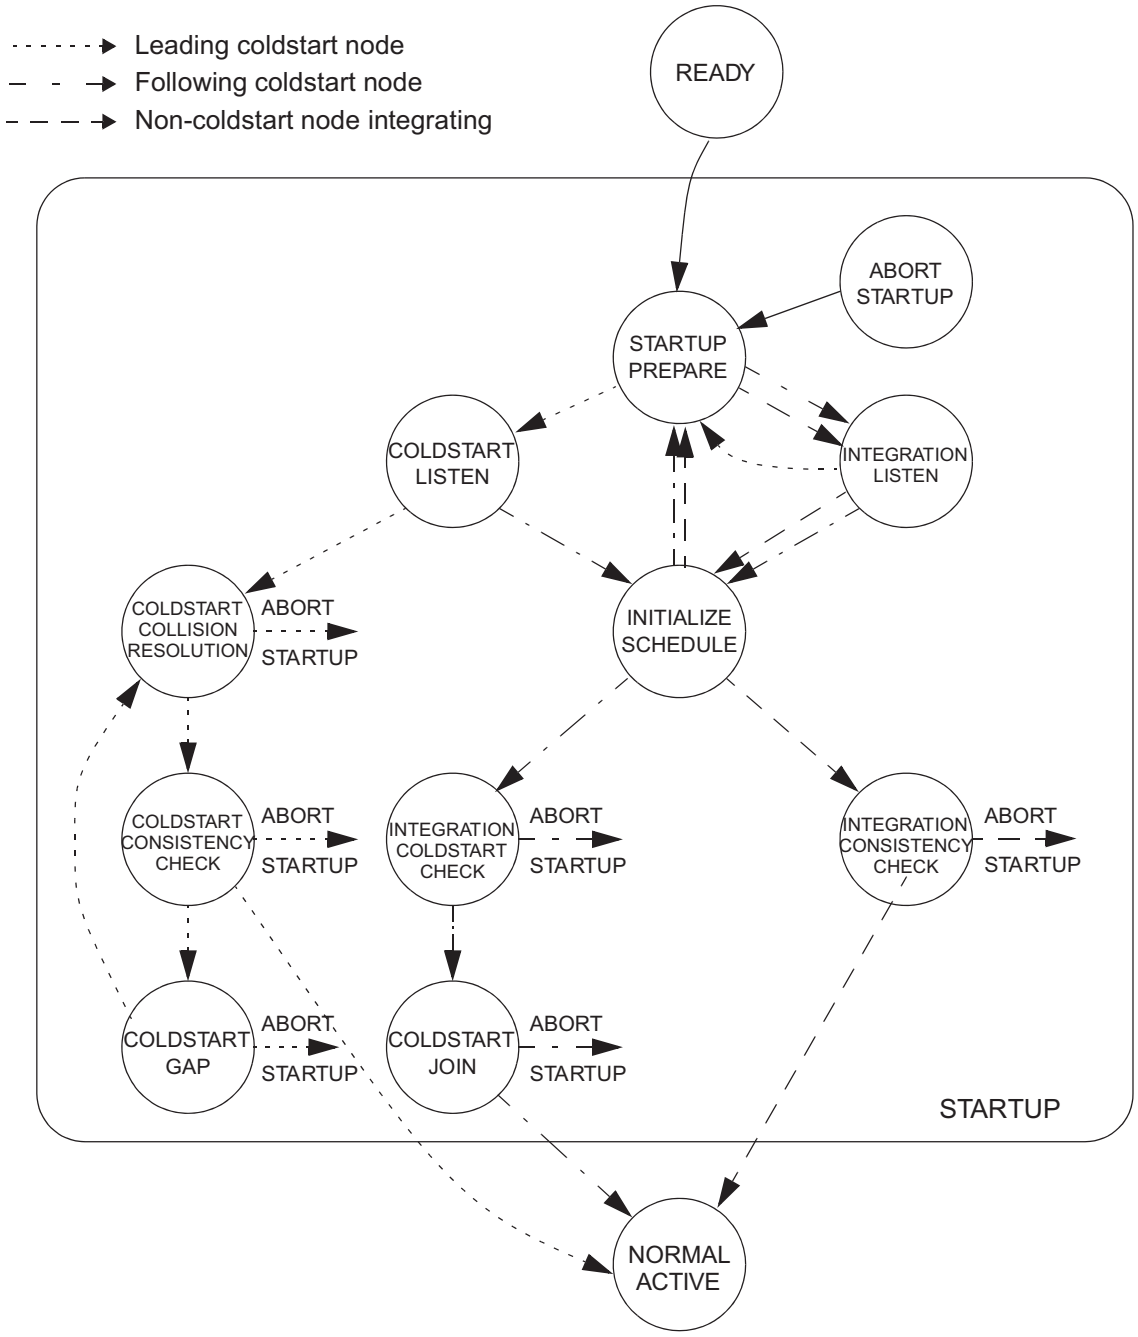
A coldstart node has bits SUCC1.TXST and SUCC1.TXSY set to 1. Message buffer 0 holds the key slot ID which defines the slot number where the startup frame is sent. The startup frame indicator bit is set in the frame header of the startup frame.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each startup frame must also be a sync frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by SUCC1.CSA(4-0) in the SUC configuration register 1.

A non-coldstart node requires at least two startup frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration through the integration path as soon as they receive sync frames from which to derive the TDMA schedule information. During integration the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.



26.2.6.7.1 Coldstart Inhibit Mode

In coldstart inhibit mode, the node is prevented from initializing the TDMA communication schedule. If the CCSV.CSI bit in the communication controller status vector register is set, the node is not allowed to initialize the cluster communication, that is, entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup frames after another coldstart node starts the initialization of the cluster communication.

The coldstart inhibit bit CCSV.CSI is set whenever the POC enters READY state. The bit has to be cleared under control of the host by CHI command ALLOW_COLDSTART (SUCC1.CMD(3-0) = 1001).

Copyright © 2018, Texas Instruments Incorporated

Figure 26-15. State Diagram Time-Triggered Startup

Copyright © 2018, Texas Instruments Incorporated

26.2.6.7.2 Startup Timeouts

The communication controller supplies two different μT timers supporting two timeout values, startup timeout and startup noise timeout. The two timers are started when the communication controller enters the COLDSTART_LISTEN state. The expiration of either of these timers causes the node to leave the initial sensing phase (COLDSTART_LISTEN state) with the intention of starting up communication.

NOTE: The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values SUCC2.LT(20-0) and SUCC2.LTN(3-0) from the SUC configuration register 2.

26.2.6.7.2.1 Startup Timeout

The startup timeout limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others. The startup timer is configured by programming SUCC2.LT(20-0) in the SUC configuration register 2.

The startup timeout time can be calculated from the contents of SUCC2.LT(20-0) (Refer to the FlexRay Protocol Specification: pdListenTimeout)

The startup timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Both channels reaching idle state while in COLDSTART_LISTEN state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the COLDSTART_LISTEN state
- When the COLDSTART_LISTEN state is left

Once the startup timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

26.2.6.7.2.2 Startup Noise Timeout

At the same time the startup timer is started for the first time (transition from STARTUP_PREPARE state to COLDSTART_LISTEN state), the startup noise timer is started. This additional timeout is used to improve reliability of the startup procedure in the presence of noise. The startup noise timer is configured by programming SUCC2.LTN(3-0) in the SUC configuration register 2.

The startup noise timeout time can be calculated as the product of SUCC2.LT(20-0) * SUCC2.LTN(3-0) (Refer to the FlexRay Protocol Specification: pdListenTimeout • gListenNoise)

The startup noise timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Reception of correctly decoded headers or CAS symbols while the node is in COLDSTART_LISTEN state

The startup noise timer is stopped when the COLDSTART_LISTEN state is left.

Once the startup noise timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won't be restarted when random channel activity is sensed, this timeout defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

26.2.6.7.3 Path of Leading Coldstart Node (Initiating Coldstart)

When a coldstart node enters COLDSTART_LISTEN, it listens to its attached channels.

If no communication is detected, the node enters the COLDSTART_COLLISION_RESOLUTION state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number 0.

Copyright © 2018, Texas Instruments Incorporated

From cycle 0 on, the node transmits its startup frame. Since each coldstart node is allowed to perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a frame header during these four cycles, it re-enters the COLDSTART_LISTEN state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup frames.

After four cycles in COLDSTART_COLLISION_RESOLUTION state, the node that initiated the coldstart enters the COLDSTART_CONSISTENCY_CHECK state. It collects all startup frames from cycle four and five and performs clock correction. If the clock correction does not deliver any errors and it has received at least one valid startup frame pair, the node leaves COLDSTART_CONSISTENCY_CHECK and enters NORMAL_ACTIVE state.

The number of coldstart attempts that a node is allowed to perform is configured by SUCC1.CSA(4-0) in the SUC configuration register 1. The number of remaining coldstarts attempts can be read from CCSV.RCA(4-0) of communication controller status vector register. The number of remaining attempts is reduced by 1 for each attempted coldstart. A node may enter the COLDSTART_LISTEN state only if this value is larger than 1 and it may enter the COLDSTART_COLLISION_RESOLUTION state only if this value is larger than 0. If the number of coldstart attempts is 1, coldstart is inhibited but integration is still possible.

26.2.6.7.4 Path of Following Coldstart Node (Responding to Leading Coldstart Node)

When a coldstart node enters the COLDSTART_LISTEN state, it tries to receive a valid pair of startup frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid startup frame has been received, the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_COLDSTART_CHECK state is entered.

In INTEGRATION_COLDSTART_CHECK state, it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all sync frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient frames from the same node it has integrated on, the COLDSTART_JOIN state is entered.

In COLDSTART_JOIN state, following coldstart nodes begin to transmit their own startup frames and continue to do so in subsequent cycles. Thereby, the leading coldstart node and the nodes joining it can check if their schedules agree with each other. If the clock correction signals any error, the node aborts the integration attempt. If a node in this state sees at least one valid startup frame during all even cycles in this state and at least one valid startup frame pair during all double cycles in this state, the node leaves COLDSTART_JOIN state and enters NORMAL_ACTIVE state. Thereby it leaves STARTUP at least one cycle after the node that initiated the coldstart.

26.2.6.7.5 Path of Non-Coldstart Node

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels.

As soon as a valid startup frame has been received the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_CHECK state is entered.

In INTEGRATION_CONSISTENCY_CHECK state it is verified that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) send startup frames that agree with the nodes own schedule. Clock correction is activated, and if any errors are signaled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup frames or the startup frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid startup frame pairs or the startup frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

Copyright © 2018, Texas Instruments Incorporated

If after the first double-cycle less than two valid startup frames are received within an even cycle, or less than two valid startup frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid startup frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

26.2.6.8 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering STARTUP through the coldstart path) and one additional node have entered the NORMAL_ACTIVE state, the startup phase for the cluster has finished. In the NORMAL_ACTIVE state, all configured messages are scheduled for transmission. This includes all data frames as well as the sync frames. Rate and offset measurement is started in all even cycles (even/odd cycle pairs required).

In NORMAL_ACTIVE state the communication controller supports regular communication functions:

- The communication controller performs transmissions and reception on the FlexRay bus as configured
- Clock synchronization is running
- The host interface is operational

The communication controller exits from that state to:

- HALT state by writing SUCC1.CMD(3-0) = 0110 (HALT command, at the end of the current cycle)
- HALT state by writing SUCC1.CMD(3-0) = 0111 (FREEZE command, immediately)
- HALT state due to change of the error state from ACTIVE to COMM_HALT
- NORMAL_PASSIVE state due to change of the error state from ACTIVE to PASSIVE
- READY state by writing SUCC1.CMD(3-0) = 0010 (READY command)

26.2.6.9 NORMAL_PASSIVE State

NORMAL_PASSIVE state is entered from NORMAL_ACTIVE state when the error state changes from ACTIVE to PASSIVE.

In NORMAL_PASSIVE state, the node is able to receive all frames (node is fully synchronized and performs clock synchronization). Contrary to the NORMAL_ACTIVE state, the node does not actively participate in communication, that is, neither symbols nor frames are transmitted.

In NORMAL_PASSIVE state:

- The communication controller performs reception on the FlexRay bus
- The communication controller does not transmit any frames or symbols on the FlexRay bus
- Clock synchronization is running
- The host interface is operational

The communication controller exits from this state to

- HALT state by writing SUCC1.CMD(3-0) = 0110 (HALT command, at the end of the current cycle)
- HALT state by writing SUCC1.CMD(3-0) = 0111 (FREEZE command, immediately)
- HALT state due to change of the error state from PASSIVE to COMM_HALT
- NORMAL_ACTIVE state due to change of the error state from PASSIVE to ACTIVE. The transition takes place when CCEV.PTAC(4-0) equals SUCC1.PTA(4-0) - 1.
- To READY state by writing SUCC1.CMD(3-0) = 0010 (READY command)

26.2.6.10 HALT State

In this state all communication (reception and transmission) is stopped.

The communication controller enters this state:

- By writing SUCC1.CMD(3-0) = 0110 (HALT command) while the communication controller is in NORMAL_ACTIVE or NORMAL_PASSIVE state

Copyright © 2018, Texas Instruments Incorporated

- By writing SUCC1.CMD(3-0) = 0111 (FREEZE command) from all states
- When exiting from NORMAL_ACTIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit and SUCC1.HCSE is set
- When exiting from NORMAL_PASSIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit and SUCC1.HCSE is set

The communication controller exits from this state to DEFAULT_CONFIG state

- By writing SUCC1.CMD(3-0) = 0001 (CONFIG command)

When the communication controller transits from HALT state to DEFAULT_CONFIG state all configuration and status data is maintained for analyzing purposes.

When the host writes SUCC1.CMD(3-0) = 0110 (HALT command), the communication controller sets bit CCSV.HRQ and enters HALT state at next end of cycle.

When the host writes SUCC1.CMD(3-0) = 0111 (FREEZE command), the communication controller enters HALT state immediately and sets the CCSV.FSI bit in the communication controller status vector register.

The POC state from which the transition to HALT state took place can be read from CCSV.PSL(5-0).

26.2.7 Network Management

The accrued network management (NM) vector is located in the Network Management Registers (NMV1/2/3). The communication controller performs a logical OR operation over all NM vectors out of all received valid NM frames with the Payload Preamble Indicator (PPI) bit set. Only a static frame may be configured to hold NM information. The communication controller updates the NM vector at the end of each cycle.

The length of the NM vector can be configured from 0 to 12 bytes by NEMC.NML(3-0). The NM vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay frames with the PPI bit set, the PPIT bit in the header section of the corresponding transmit buffer has to be set WRHS1.PPIT. In addition the host has to write the NM information to the data section of the corresponding transmit buffer.

The evaluation of the NM vector has to be done by the application running on the host.

NOTE: In case a message buffer is configured for transmission / reception of network management frames, the payload length configured in header 2 of that message buffer should be equal or greater than the length of the NM vector configured by NEMC.NML(3-0).When the Communication Controller transits to HALT state, the cycle count is not incremented and therefore the NM vector is not updated. In this case NMV1/2/3 holds the value from the cycle before.

26.2.8 Filtering and Masking

Filtering is done by comparison of the configuration of assigned message buffers against current slot and cycle counter values and channel ID (channel A, B). A message buffer is only updated / transmitted if the required matches occur.

Filtering is done on:

- Slot counter
- Cycle counter
- Channel ID

The following filter combinations for acceptance / transmit filtering are allowed:

- Slot counter + Channel ID
- Slot counter + Cycle counter + Channel ID

All configured filters must match in order to store a received message in a message buffer.

Copyright © 2018, Texas Instruments Incorporated

NOTE: For the FIFO the acceptance filter is configured by the FIFO Rejection Filter and the FIFO Rejection Filter mask.

A message will be transmitted in the time slot corresponding to the configured frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

26.2.8.1 Slot Counter Filtering

Every transmit and receive buffer contains a frame ID stored in the header section. This frame ID is compared against the current slot counter value in order to assign receive and transmit buffers to the corresponding slot.

If two or more message buffers are configured with the same frame ID and channel ID, and if they have a matching cycle counter filter value for the same slot, then the message buffer with the lowest message buffer number is used.

26.2.8.2 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in the header section 1 of each message buffer.

If message buffer 0 or 1 is configured to hold the startup / sync frame or the single slot frame by bits TXST, TXSY, and TSM of SUC Configuration Register 1, cycle counter filtering for message buffer 0 or 1 respectively shall be disabled.

NOTE: Sharing of a static time slot by cycle counter filtering between different nodes of a FlexRay network is not allowed.

The set of cycle numbers belonging to a cycle set is determined as described in Table 26-8.

Table 26-8. Definition of Cycle Set

Cycle Code	Matching Cycle Counter Values		
0b000000x	All cycles		
0b000000***1c***	Every second cycle	at (cycle count)mod2	= ***c***
0b00000***1cc***	Every fourth cycle	at (cycle count)mod4	= ***cc***
0b0001***ccc***	Every eighth cycle	at (cycle count)mod8	= ***ccc***
0b001***cccc***	Every sixteenth cycle	at (cycle count)mod16	= ***cccc***
0b01***ccccc***	Every thirty-second cycle	at (cycle count)mod32	= ***ccccc***
0b1***cccccc***	Every sixty-fourth cycle	at (cycle count)mod64	= ***cccccc***

Table 26-9 gives some examples for valid cycle sets to be used for cycle counter filtering.

Table 26-9. Examples for Valid Cycle Sets

Cycle Code	Matching Cycle Counter Values
0b000000***11***	1-3-5-7- …. -63 ↲
0b00001***00***	0-4-8-12- …. -60 ↲
0b0001***110***	6-14-22-30- …. -62 ↲
0b001***1000***	8-24-40-56 ↲
0b01***00011***	3-35 ↲
0b1***001001***	9 ↲

Copyright © 2018, Texas Instruments Incorporated

The received message is stored only if the cycle counter value of the cycle during which the message is received matches an element of the receive buffer's cycle set. Other filter criteria must also be met.

The content of a transmit buffer is transmitted on the configured channel(s) when an element of the cycle set matches the current cycle counter value. Other filter criteria must also be met.

26.2.8.3 Channel ID Filtering

There is a 2-bit channel filtering field (CHA, CHB) located in the header section of each message buffer in the message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see Table 26-10).

Table 26-10. Channel Filtering Configuration

CHA	CHB	Transmit Buffer Transmit frame	Receive Buffer Store valid receive frame
1	1	On both channels (static segment only)	Received on channel A or B (store first semantically valid frame, static segment only)
1	0	On channel A	Received on channel A
0	1	On channel B	Received on channel B
0	0	No transmission	Ignore frame

The contents of a transmit buffer is transmitted on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be set up for transmission on both channels (CHA and CHB set).

Valid received frames are stored if they are received on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a receive buffer may be setup for reception on both channels (CHA and CHB set).

NOTE: If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no frames are transmitted and received frames are ignored (same function as CHA = CHB = 0)

26.2.8.4 FIFO Filtering

For FIFO filtering there is one rejection filter and one rejection filter mask available. The FIFO filter consists of channel filter FRF.CH(1-0), frame ID filter FRF.FID(10-0), and cycle counter filter FRF.CYF(6-0). Registers FRF and FRFM can be configured in DEFAULT_CONFIG or CONFIG state only. The filter configuration in the header section of message buffers belonging to the FIFO is ignored.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by FRF.CYF(6-0), all frames are rejected.

A valid received frame is stored in the FIFO if channel ID, frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

Copyright © 2018, Texas Instruments Incorporated

26.2.9 Transmit Process

26.2.9.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the frame ID corresponding to the next sending slot is selected for transmission.

The data section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the input buffer has to be started by writing to the Input Buffer Command Request Register latest at this time.

26.2.9.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest frame ID) is selected next. In the dynamic segment different slot counter sequences on channel A and channel B are possible (concurrent sending of different frame IDs on both channels).

The data section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the input buffer has to be started by writing to the Input Buffer Command Request Register latest at this time.

The start of latest transmit configured by MHDC.SLT(12-0) in the MHD configuration register 1 defines the maximum minislot value allowed before inhibiting new frame transmission in the dynamic segment of the current cycle.

26.2.9.3 Transmit Buffers

Communication Controller message buffers can be configured as transmit buffers by programming bit CFG in the header section of the corresponding message buffer to 1 in WRHS1.

There exist the following possibilities to assign a transmit buffer to the communication controller channels:

- Static segment:
  - channel A or channel B
  - channel A and channel B
- Dynamic segment:
  - channel A or channel B

Message buffer 0 or 1 is dedicated to hold the startup frame, the sync frame, or the designated single slot frame as configured by SUCC1.TXST, SUCC1.TXSY, and SUCC1.TSM in the SUC Configuration register 1. In this case it can be reconfigured in DEFAULT_CONFIG or CONFIG state only. This ensures that any node transmits at most one startup / sync frame per communication cycle. Transmission of startup / sync frames from other message buffers is not possible.

All other message buffers configured for transmission in static or dynamic segment are reconfigurable during runtime depending on the configuration of MRC.SEC(1-0). Due to the organization of the data partition in the message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the header section of a message buffer may lead to erroneous configurations.

If a message buffer is reconfigured (header section updated) during runtime, it may happen that this message buffer is not sent out in the currently active communication cycle.

The communication controller does not have the capability to calculate the header CRC. The host is supposed to provide the header CRCs for all transmit buffers. If network management is required the host has to set the PPIT bit in the header section of the corresponding message buffer to 1 and write the network management information to the data section of the message buffer.

The payload length field configures the data payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by MHDC.SFDL(6-0) in the message handler configuration register 1, the communication controller generates padding bytes to ensure that frames have proper physical length. The padding pattern is logical 0.

Copyright © 2018, Texas Instruments Incorporated

NOTE: In case of an odd payload length (PLC=1,3,5,...) the application needs to write zeros to the last 16 bit of the message buffers data section to ensure that the padding pattern is all zeros.

Each transmit buffer provides a transmission mode flag TXM that allows the host to configure the transmission mode for the transmit buffer. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode.

In single-shot mode the Communication Controller resets the corresponding TXR flag after transmission has completed after which the host may update the transmit buffer.

In continuous mode, the Communication Controller does not reset the corresponding transmission request flag TXR after successful transmission. In this case a frame is sent out each time the filter criteria match. The TXR flag can be reset by the Host by writing the corresponding message buffer number to the IBCR register while bit IBCM.STXRH is set to 0.

If two or more transmit buffers meet the filter criteria simultaneously, the transmit buffer with the lowest message buffer number will be transmitted in the corresponding slot.

26.2.9.4 Frame Transmission

The following steps are required to prepare a message buffer for transmission:

- Configure the transmit buffer in the Message RAM through WRHS1, WRHS2, and WRHS3
- Write the data section of the transmit buffer through WRDSn
- Transfer the configuration and message data from Input Buffer to the Message RAM by writing the number of the target message buffer to register IBCR
- If configured in the Input Buffer Command Mask (IBCM) register the Transmission request flag (TXR) for the corresponding message buffer will be set as soon as the transfer has completed, and the message buffer is ready for transmission.
- Check whether the message buffer has been transmitted by checking the TXR bits (TXR = 0) in the Transmission request 1,2,3,4 registers (single-shot mode only).

After transmission has completed, the corresponding TXR flag in the Transmission request 1,2,3,4 register is reset (single- shot mode), and, if bit MBI in the header section of the message buffer is set, flag SIR.TXI in the Status Interrupt register is set to 1. If enabled, an interrupt is generated.

26.2.9.5 Null Frame Transmission

If in static segment the host does not set the transmission request flag before transmit time, and if there is no other transmit buffer with matching filter criteria, the communication controller transmits a null frame with the null frame indication bit set and the payload data cleared to 0.

In the following cases the communication controller transmits a null frame:

- If the message buffer with the lowest message buffer number matching the filter criteria does not have its transmission request flag set (TXR = 0).
- No transmit buffer configured for the slot has a cycle counter filter that matches the current cycle. In this case, no message buffer status MBS is updated.

Null frames are not transmitted in the dynamic segment.

Copyright © 2018, Texas Instruments Incorporated

26.2.10 Receive Process

26.2.10.1 Dedicated Receive Buffers

A portion of the Communication Controller message buffers can be configured as dedicated receive buffers by programming bit CFG in the header section of the corresponding message buffer to 0. This can be done through the Write Header Section 1 register.

The following possibilities exist to assign a receive buffer to the Communication Controller channels:

- Static segment:
  - channel A or channel B
  - channel A and channel B (the communication controller stores the first semantically valid frame)
- Dynamic segment:
  - channel A or channel B

The communication controller transfers payload data of valid received messages from the shift registers of the FlexRay protocol controller (channel A or B) to the receive buffer with the matching filter configuration. A receive buffer stores all frame elements except the frame CRC.

All message buffers configured for reception in static or dynamic segment are reconfigurable during runtime depending on the configuration of MRC.SEC(1-0) of the Message RAM Configuration register. If a message buffer is reconfigured (header section updated) during runtime it may happen that in the currently active communication cycle a received message is lost.

If two or more receive buffers meet the filter criteria simultaneously, the receive buffer with the lowest message buffer number is updated with the received message.

26.2.10.2 Frame Reception

The following steps are required to prepare a dedicated message buffer for reception:

- Configure the receive buffer in the Message RAM through WRHS1, WRHS2, and WRHS3
- Transfer the configuration from input buffer to the message RAM by writing the number of the target message buffer to the Input Buffer Command Request (IBCR) register.

Once these steps are performed, the message buffer functions as an active receive buffer and participates in the internal acceptance filtering process, which takes place every time the communication controller receives a message. The first matching receive buffer is updated from the received message.

If a valid payload segment was stored in the data section of a message buffer, the corresponding ND flag in the NDAT1,2,3,4 registers is set, and, if bit MBI in the header section of that message buffer is set, flag SIR.RXI in the Status Interrupt Register is set to 1. If enabled, an interrupt is generated.

In case that bit ND was already set when the Message Handler updates the message buffer, bit MBS.MLST of the corresponding message buffer is set and the unprocessed message data is lost.

If no frame, a null frame, or a corrupted frame is received in a slot, the data section of the message buffer configured for this slot is not updated. In this case only the flags in the corresponding message buffer status (MBS) is updated.

When the Message Handler changes the message buffer status MBS in the header section of a message buffer, the corresponding MBC flag in the Message Buffer Status Changed 1,2,3 or 4 register is set, and if bit MBI in the header section of that message buffer is set, flag SIR.MBSI in the Status Interrupt Register is set to 1. If enabled an interrupt is generated.

If the payload length of a received frame PLR(6-0) is longer than the value programmed by PLC(6-0) in the header section of the corresponding message buffer, the data field stored in the message buffer is truncated to that length.

NOTE: The ND and MBS flags are automatically cleared by the message handler when the payload data and the header of a received message have been transferred to the output buffer, respectively.

Copyright © 2018, Texas Instruments Incorporated

26.2.10.3 Null Frame Reception

The payload segment of a received null frame is not copied into the matching dedicated receive buffer. If a null frame has been received, only the message buffer status MBS of the matching message buffer is updated from the received null frame. All bits in header 2 and 3 of the matching message buffer remain unchanged. They are updated from received data frames only.

26.2.11 FIFO Function

26.2.11.1 Description

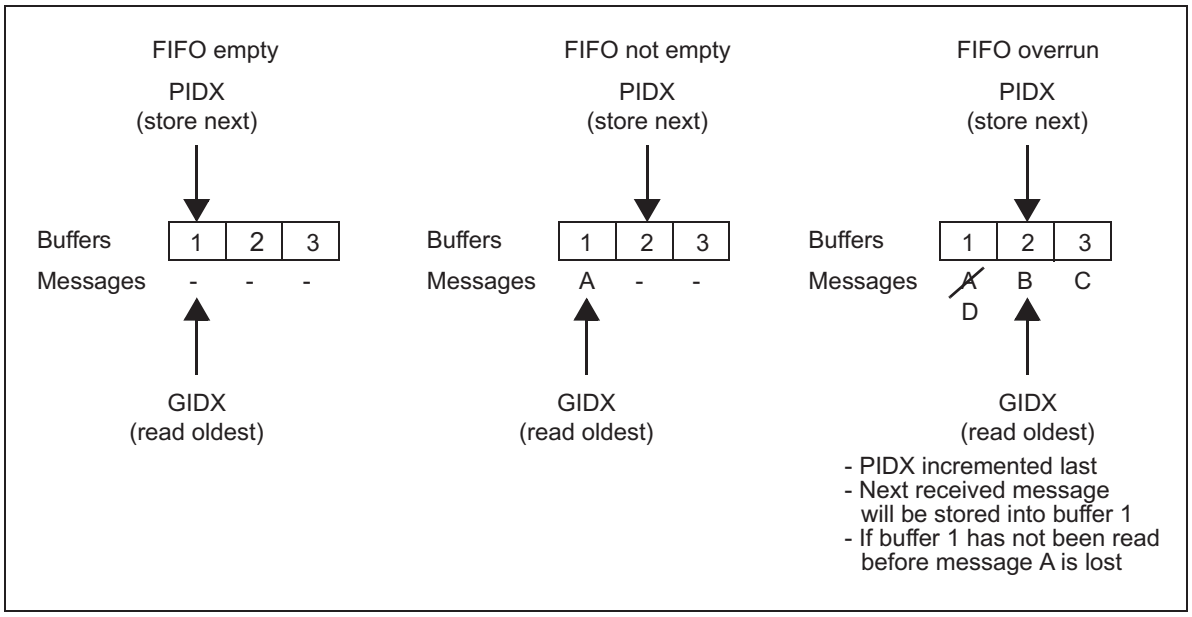
A group of the message buffers can be configured as a cyclic First-In-First-Out (FIFO) buffer. The group of message buffers belonging to the FIFO is contiguous in the register map starting with the message buffer referenced by MRC.FFB(7-0) and ending with the message buffer referenced by MRC.LCB(7-0) in the message RAM configuration register. Up to 128 message buffers can be assigned to the FIFO.

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case frame ID, payload length, receive cycle count, and the message buffer status MBS of the addressed FIFO message buffer are overwritten with frame ID, payload length, receive cycle count, and the status from the received frame. Bit SIR.RFNE in the status interrupt register shows that the FIFO is not empty, bit SIR.RFCL is set when the receive FIFO fill level FSR.RFFL(7-0) is equal or greater than the critical level as configured by FCL.CL(7-0), bit EIR.RFO shows that a FIFO overrun has been detected. If enabled, interrupts are generated.

If null frames are not rejected by the FIFO rejection filter, the null frames will be treated like data frames when they are stored into the FIFO.

There are two index registers associated with the FIFO. The PUT Index register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the message buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available message buffer. If the PIDX register is incremented past the highest numbered message buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) message buffer in the FIFO chain. The GET Index register (GIDX) is used to address the next message buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a message buffer belonging to the FIFO to the output buffer. The PUT Index register and the GET Index register are not memory mapped and are not accessible by the host CPU.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message overwrites the oldest message in the FIFO. This will set FIFO overrun flag EIR.RFO in the error interrupt register.



A FIFO not empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag SIR.RFNE is set. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in Figure 26-16 for a three message buffer FIFO.

The programmable FIFO Rejection Filter register (FRF) defines a filter pattern for messages to be rejected. The FIFO rejection filter consists of channel filter, frame ID filter, and cycle counter filter. If bit FRF.RSS is set to 1 (default), all messages received in the static segment are rejected by the FIFO. If bit FRF.RNF is set to 1 (default), received null frames are not stored in the FIFO.

The FIFO Rejection Filter mask register (FRFM) specifies which bits of the frame ID filter in the FIFO Rejection Filter register are marked don’t care for rejection filtering.

Copyright © 2018, Texas Instruments Incorporated

Figure 26-16. FIFO Status: Empty, Not Empty, and Overrun

26.2.11.2 Configuration of the FIFO

(Re)configuration of message buffers belonging to the FIFO is only possible when the Communication Controller is in DEFAULT_CONFIG or CONFIG state. While the Communication Controller is in DEFAULT_CONFIG or CONFIG state, the FIFO function is not available.

For all message buffers belonging to the FIFO should have the same payload length configured in WRHS2.PLC(6-0) of the Write Header Section 2 register. The data pointer to the first 32-bit word in the data section of the corresponding message buffer has to be configured by WRHS3.DP(10-0).

All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask. With the exception of DP and PLC, the values configured in the header sections of the message buffers belonging to the FIFO are irrelevant.

NOTE: It is recommended to program the MBI bits of the message buffers belonging to the FIFO to 0 by WRHS1.MBI to avoid RX interrupts to be generated.

If the payload length of a received frame is longer than the value programmed by WRHS2.PLC(6-0) in the header section of the corresponding message buffer, the data field stored in a message buffer of the FIFO is truncated to that length.

26.2.11.3 Access to the FIFO

For FIFO access outside DEFAULT_CONFIG and CONFIG state, the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first message buffer of the FIFO (referenced by MRC.FFB(7-0)) to the Output Buffer Command Request (OBCR) register. The message handler then transfers the message buffer addressed by the GET Index register (GIDX) to the output buffer. After this transfer the GET Index register (GIDX) is incremented.

26.2.12 Message Handling

The message handler controls data transfers between the input / output buffer and the message RAM and between the message RAM and the two transient buffer RAMs. All accesses to the internal RAMs are 32 bit accesses.

Copyright © 2018, Texas Instruments Incorporated

Access to the message buffers stored in the message RAM is done under control of the message handler state machine. This avoids conflicts between accesses of the two protocol controllers and the host CPU to the message RAM.

Frame IDs of message buffers assigned to the static segment have to be in the range from 1 to GTU7.NSS(9-0) as configured in the GTU configuration register 7. Frame IDs of message buffers assigned to the dynamic segment have to be in the range from GTU7.NSS(9-0) + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

26.2.12.1 Reconfiguration of Message Buffers

In case that an application needs to operate with more than 128 different messages, static and dynamic message buffers may be reconfigured during FlexRay operation. This is done by updating the header section of the corresponding message buffer through Input Buffer registers WRHS1,2,3.

Reconfiguration has to be enabled through control bits MRC.SEC(1-0) in the Message RAM Configuration register.

If a message buffer has not been transmitted / updated from a received frame before reconfiguration starts, the corresponding message is lost.

The point in time when a reconfigured message buffer is ready for transmission / reception according to the reconfigured frame ID depends on the current state of the slot counter when the update of the header section has completed. Therefore it may happen that a reconfigured message buffer is not transmitted / updated from a received frame in the cycle where it was reconfigured.

The Message RAM is scanned according to Table 26-11.

Table 26-11. Scan of Message RAM

Start of Scan in Slot	Scan for Slots
1	2...15, 1 (next cycle)
8	16...23, 1 (next cycle)
16	24...31, 1 (next cycle)
24	32...39, 1 (next cycle)
....	...

A Message RAM scan is terminated with the start of NIT irrespective of it's completion. The scan of the Message RAM for slots 2 to 15 starts at the beginning of slot 1 of the current cycle. The scan of the Message RAM for slot 1 is done in the cycle before by checking in parallel to each scan of the Message RAM whether there is a message buffer configured for slot 1 of the next cycle.

The number of the first dynamic message buffer is configured by MRC.FDB(7-0) in the Message RAM Configuration register. In case a Message RAM scan starts while the Communication Controller is in dynamic segment, the scan starts with the message buffer number configured by MRC.FDB(7-0).

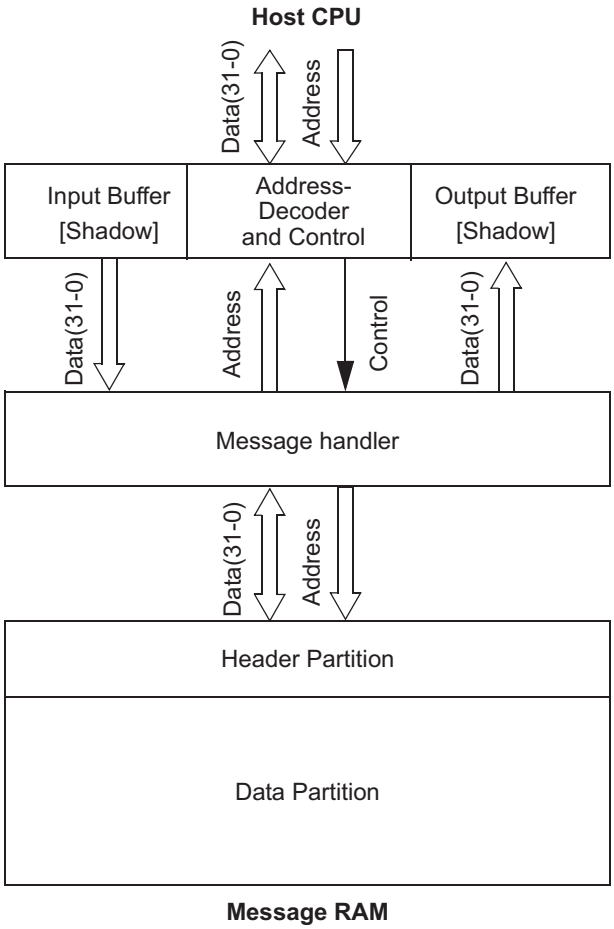
In case a message buffer needs to be reconfigured to be used in slot 1 of the next cycle, the following has to be considered:

- If the message buffer to be reconfigured for slot 1 is part of the Static Buffers, it will only be found if it is reconfigured before the last Message RAM scan in the static segment of the current cycle evaluates this message buffer.
- If the message buffer to be reconfigured for slot 1 is part of the Static + Dynamic Buffers, it will be found if it is reconfigured before the last Message RAM scan in the current cycle evaluates this message buffer.
- The start of NIT terminates the Message RAM scan. In case the Message RAM scan has not evaluated the reconfigured message buffer until this point in time, the message buffer will not be considered for the next cycle.

Copyright © 2018, Texas Instruments Incorporated

NOTE: Reconfiguration of message buffers may lead to the loss of messages and therefore has to be used very carefully. In worst case (reconfiguration in consecutive cycles) it may happen that a message buffer is never transmitted / updated from a received frame.

26.2.12.2 Host Access to Message RAM



The message transfer between input buffer and message RAM as well as between message RAM and output buffer is triggered by the host CPU by writing the number of the target / source message buffer to be accessed to the input or output buffer command request register (IBCR/OBCR).

The input / output buffer command mask registers can be used to write / read header and data section of the selected message buffer separately.

If bit IBCM.STXR in the input buffer command mask register is set (STXR = 1), the transmission request flag TXR of the selected message buffer is automatically set after the message buffer has been updated. If bit IBCM.STXR in the input buffer command mask register is reset (STXR = 0), the transmission request flag TXR of the selected message buffer is reset. This can be used to stop transmission from message buffers operated in continuous mode.

Input buffer (IBF) and the output buffer (OBF) are built up as a double buffer structure. One half of this double buffer structure is accessible by the host CPU (IBF host / OBF host), while the other half (IBF shadow / OBF shadow) is accessed by the message handler for data transfers between IBF / OBF and message RAM.

Figure 26-17. Host Access to Message RAM

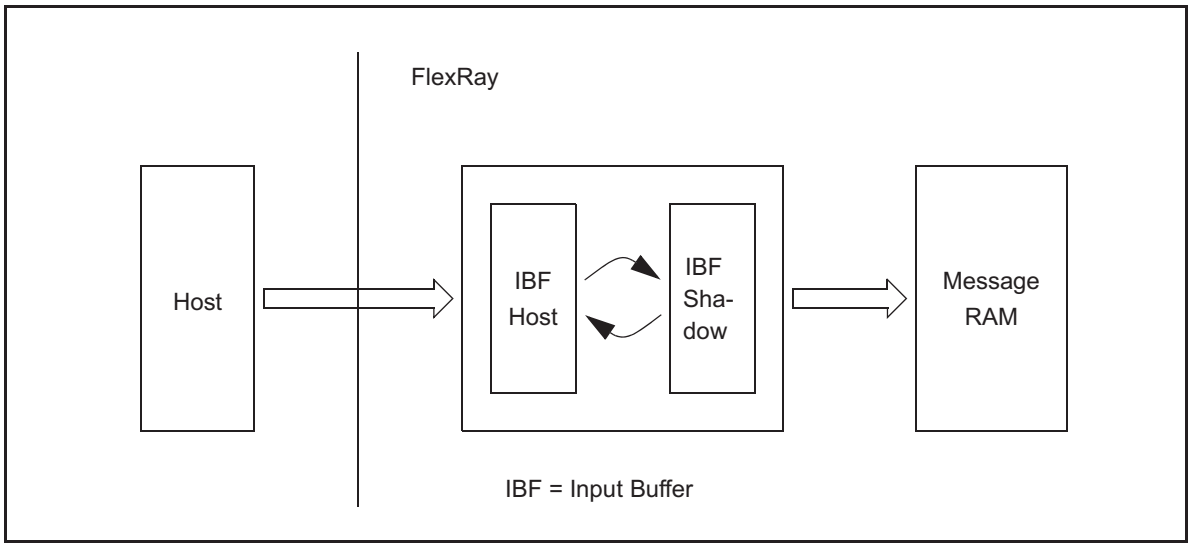
Copyright © 2018, Texas Instruments Incorporated

26.2.12.2.1 Data Transfer from Input Buffer to Message RAM

To configure / update a message buffer in the message RAM, the host has to write the data to WRDSn and the header to WRHS1…3. The specific action is selected by configuring the input buffer command mask IBCM.

When the host writes the number of the target message buffer in the message RAM to IBCR.IBRH(6-0) in the input buffer command request register IBCR, IBF host and IBF shadow are swapped (Figure 26-18).

Figure 26-18. Double Buffer Structure Input Buffer



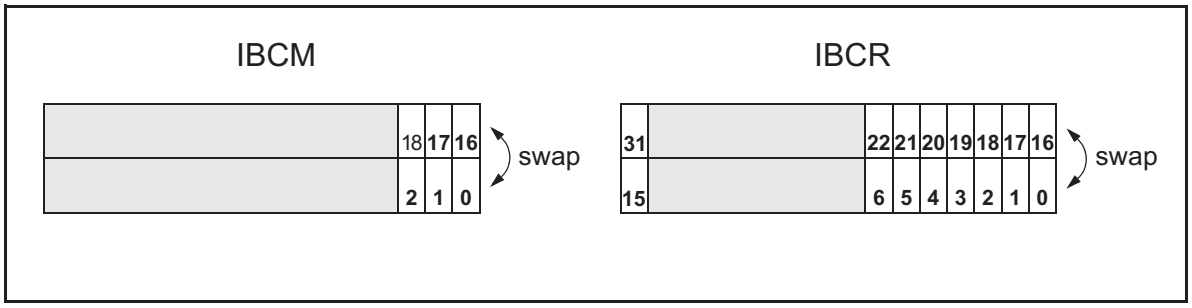


Figure 26-19. Swapping of IBCM and IBCR Bits

With this write operation the IBCR.IBSYS bit in the input buffer command request register is set to 1. The message handler then starts to transfer the contents of IBF shadow to the message buffer in the message RAM selected by IBCR.IBRS(6-0).

While the message handler transfers the data from IBF shadow to the target message buffer in the message RAM, the host may write the next message to IBF host. After the transfer between IBF shadow and the message RAM has completed, the IBCR.IBSYS bit is set back to 0 and the next transfer to the message RAM may be started by the host by writing the corresponding target message buffer number to IBCR.IBRH(6-0) in the input buffer command request register.

If a write access to IBCR.IBRH(6-0) occurs while IBCR.IBSYS is 1, IBCR.IBSYH is set to 1. After completion of the ongoing data transfer from IBF shadow to the message RAM, IBF host and IBF shadow are swapped, IBCR.IBSYH is reset to 0, IBCR.IBSYS remains set to 1, and the next transfer to the message RAM is started. In addition the message buffer numbers stored under IBCR.IBRH(6-0) and IBCR.IBRS(6-0) and the command mask flags are also swapped.

Copyright © 2018, Texas Instruments Incorporated

Example of a 8/16/32-bit host access sequence:

- Configure / update n-th message buffer through IBF
- Wait until IBCR.IBSYH is reset
- Write data section to WRDSn
- Write header section to WRHS1,2,3
- Write command mask: write IBCM.STXRH, IBCM.LHSH, IBCM.LDSH
- Demand data transfer to target message buffer: write IBCR.IBRH(6-0)

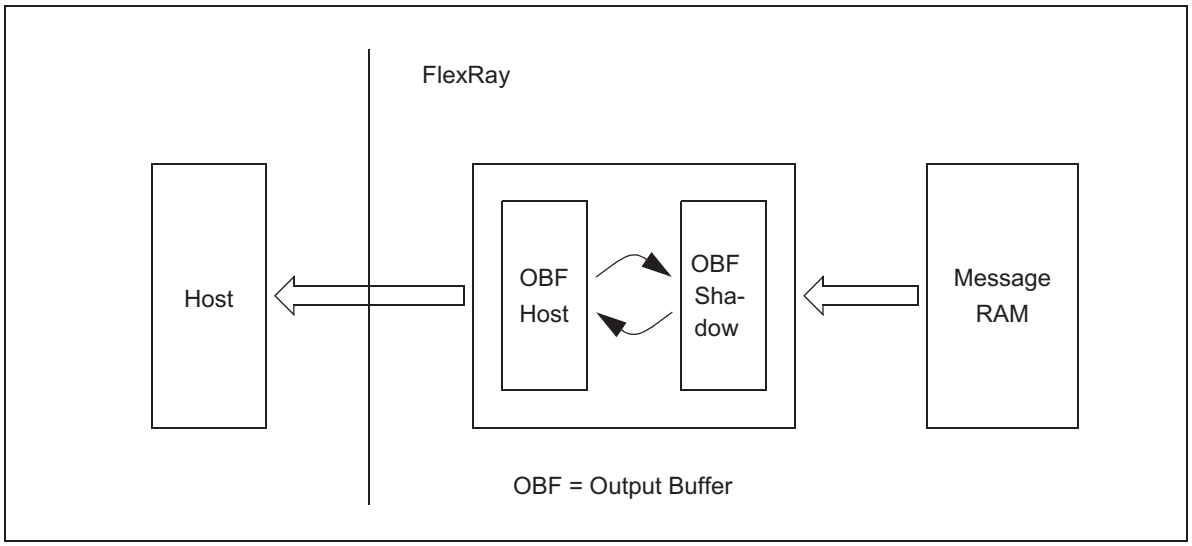
Configure / update further message buffer through IBF in the same way.

NOTE: Any write access to IBF while IBCR.IBSYH is 1 will set error flag EIR.IIBA in the Error Interrupt Register to 1. In this case the write access has no effect.

Table 26-12. Assignment of Input Buffer Command Mask Bits

Position	Access	Bit	Function
18	r	STXRS	Set Transmission Request shadow ongoing or finished
17	r	LDSS	Load Data Section shadow ongoing or finished
16	r	LHSS	Load Header Section shadow ongoing or finished
2	r/w	STXRH	Set Transmission Request Host
1	r/w	LDSH	Load Data Section Host
0	r/w	LHSH	Load Header Section Host

Table 26-13. Assignment of Input Buffer Command Request Bits



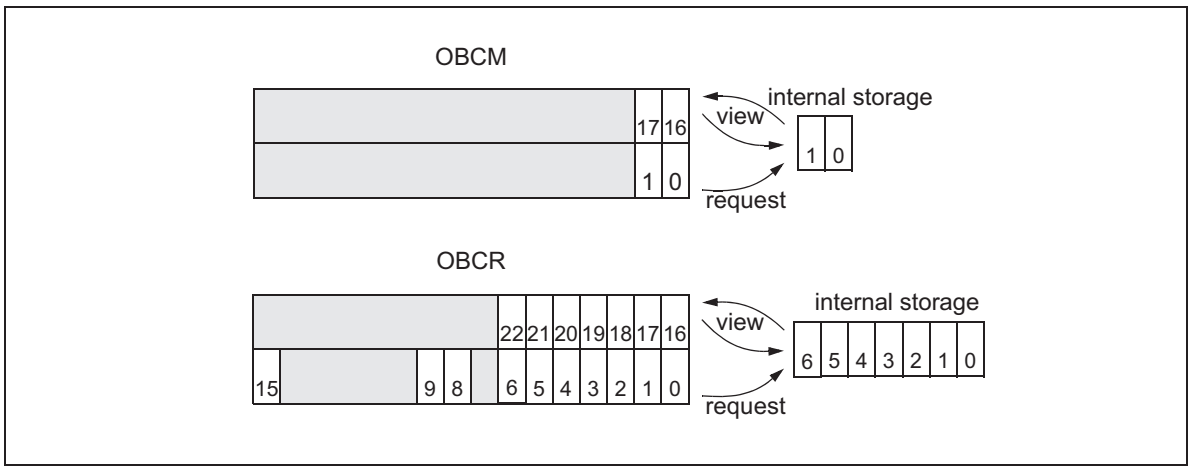
Position	Access	Bit	Function
31	r	IBSYS	IBF Busy Shadow, signals ongoing transfer from IBF shadow to message RAM
22-16	r	IBRS(6-0)	IBF Request Shadow, number of message buffer currently / last updated
15	r	IBSYH	IBF Busy Host, transfer request pending for message buffer referenced by IBRH(6-0)
6-0	r/w	IBRH(6-0)	IBF Request Host, number of message buffer to be updated next

26.2.12.2.2 Data Transfer from Message RAM to Output Buffer

To read out a message buffer from the message RAM, the host has to write to the output buffer command mask and command request register to trigger the data transfer. After a transfer has completed the host can read the transferred data from the RDDSn, RDHS1,2,3, and MBS.

Copyright © 2018, Texas Instruments Incorporated

Figure 26-20. Double Buffer Structure Output Buffer



OBF host and OBF shadow as well as bits OBCM.RHSS, OBCM.RDSS, OBCM.RHSH, OBCM.RDSH from the output buffer command mask register and bits OBCM.OBRS(6-0), OBCM.OBRH(6-0) from the output buffer command request register are swapped under control of bits OBCR.VIEW and OBCR.REQ from the output buffer command request register.

Writing bit OBCR.REQ in the output buffer command request register to 1 copies bits OBCM.RHSS, OBCM.RDSS from the output buffer command mask register and bits OBCR.OBRS(6-0) from the output buffer command request register to an internal storage (see Figure 26-21).

After setting OBCR.REQ to 1, OBCR.OBSYS is set to 1, and the transfer of the message buffer selected by OBCR.OBRS(6-0) from the message RAM to OBF shadow is started. After the transfer between the message RAM and OBF shadow has completed, the OBCR.OBSYS bit is set back to 0. Bits OBCR.REQ and OBCR.VIEW can only be set to 1 while OBCR.OBSYS is 0.

Figure 26-21. Swapping of OBCM and OBCR Bits

OBF host and OBF shadow are swapped by setting bit OBCR.VIEW in the output buffer command request register to 1 while bit OBCR.OBSYS is 0 (see Figure 26-20).

Copyright © 2018, Texas Instruments Incorporated

In addition bits OBCR.OBRH(6-0) are swapped with the output buffer command request registers internal storage and bits OBCM.RHSH, OBCM.RDSH are swapped with the output buffer command mask registers internal storage thus assuring that the message buffer number stored in OBCR.OBRH(6-0) and the mask configuration stored in OBCM.RHSH, OBCM.RDSH matches the transferred data stored in OBF host (see Figure 26-21).

Now the host can read the transferred message buffer from OBF host while the message handler may transfer the next message from the message RAM to OBF shadow.

NOTE: If bits REQ and VIEW are set to 1 with the same write access while OBSYS is 0, OBSYS is automatically set to 1 and OBF shadow and OBF host are swapped. Additionally mask bits OBCM.RDSH and OBCM.RHSH are swapped with the registers internal storage to keep them attached to the corresponding Output Buffer transfer. Afterwards OBRS (6-0) is copied to the register internal storage, mask bits OBCM.RDSS and OBCM.RHSS are copied to register OBCM internal storage, and the transfer of the selected message buffer from the Message RAM to OBF shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF Host. When the current transfer between Message RAM and OBF shadow has completed, this is signaled by setting OBSYS back to 0.

Example of an 8/16/32-bit host access to a single message buffer:

If a single message buffer has to be read out, two separate write accesses to OBCR.REQ and OBCR.VIEW are necessary:

- Wait until OBCR.OBSYS is reset
- Write Output Buffer Command Mask OBCM.RHSS, OBCM.RDSS
- Request transfer of message buffer to OBF Shadow by writing OBCR.OBRS(6-0) and OBCR.REQ (in case of and 8-bit Host interface, OBCR.OBRS(6-0) has to be written before OBCR.REQ).
- Wait until OBCR.OBSYS is reset
- Toggle OBF Shadow and OBF Host by writing OBCR.VIEW = 1
- Read out transferred message buffer by reading RDDSn, RDHS1,2,3, and MBS

Example of an 8/16/32-bit host access sequence:

Request transfer of 1st message buffer to OBF shadow

- Wait until OBCR.OBSYS is reset
- Write Output Buffer Command Mask OBCM.RHSS, OBCM.RDSS for 1st message buffer
- Request transfer of 1st message buffer to OBF Shadow by writing OBCR.OBRS(6-0) and OBCR.REQ (in case of an 8-bit Host interface, OBCR.OBRS(6-0) has to be written before OBCR.REQ).

Toggle OBF Shadow and OBF Host to read out 1st transferred message buffer and request transfer of 2nd message buffer:

Request transfer of 2nd message buffer to OBF shadow, read out 1st message buffer from OBF host

- Wait until OBCR.OBSYS is reset
- Write Output Buffer Command Mask OBCM.RHSS, OBCM.RDSS for 2nd message buffer
- Toggle OBF Shadow and OBF Host and start transfer of 2nd message buffer to OBF Shadow simultaneously by writing OBCR.OBRS(6-0) of 2nd message buffer, OBCR.REQ, and OBCR.VIEW (in case of and 8-bit Host interface, OBCR.OBRS(6-0) has to be written before OBCR.REQ and OBCR.VIEW).
- Read out 1st transferred message buffer by reading RDDSn, RDHS13, and MBS

For further transfers continue the same way.

Demand access to last requested message buffer without request of another message buffer:

- Wait until OBCR.OBSYS is reset
- Demand access to last transferred message buffer by writing OBCR.VIEW
- Read out last transferred message buffer by reading RDDSn, RDHS1,2,3, and MBS

Copyright © 2018, Texas Instruments Incorporated

Table 26-14. Assignment of Output Buffer Command Mask Bits

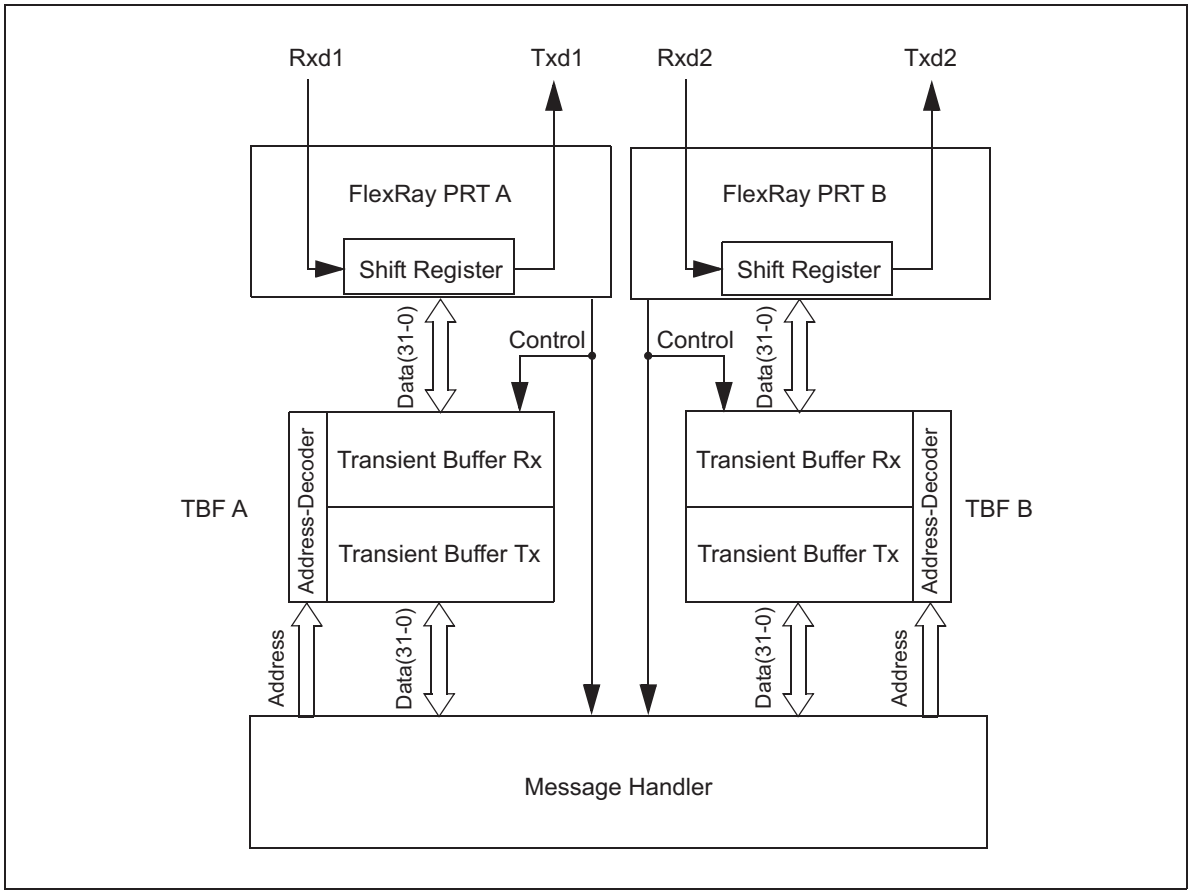
Position	Access	Bit	Function
17	r	RDSH	Read Data Section Host access
16	r	RHSH	Read Header Section Host access
1	r/w	RDSS	Read Data Section Shadow
0	r/w	RHSS	Read Header Section Shadow

Table 26-15. Assignment of Output Buffer Command Request Bits

Position	Access	Bit	Function
22-16	r	OBRH(6-0)	OBF Request Host, number of message buffer available for host access
15	r	OBSYS	OBF Busy Shadow, signals ongoing transfer from message RAM to OBF Shadow
9	r/w	REQ	Request Transfer from message RAM to OBF Shadow
8	r/w	VIEW	View OBF Shadow, swap OBF Shadow and OBF Host
6-0	r/w	OBRS(6-0)	OBF Request Shadow, number of message buffer for next request

26.2.12.3 FlexRay Protocol Controller Access to Message RAM

The two transient buffer RAMs (TBF A,B) are used to buffer the data for transfer between the two FlexRay channel protocol controllers and the message RAM.



Each transient buffer RAM is built up as a double buffer, able to store two complete FlexRay messages. There is always one buffer assigned to the corresponding protocol controller while the other one is accessible by the message handler.

If, for example, the message handler writes the next message to be sent to transient buffer Tx, the FlexRay Channel protocol controller can access transient buffer Rx to store the message it is currently receiving. During transmission of the message stored in transient buffer Tx, the message handler transfers the last received message stored in transient buffer Rx to the message RAM (if it passes acceptance filtering) and updates the corresponding message buffer.

Data transfers between the transient buffer RAMs and the shift registers of the FlexRay channel protocol controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay messages.

Copyright © 2018, Texas Instruments Incorporated

Figure 26-22. Access to Transient Buffer RAMs

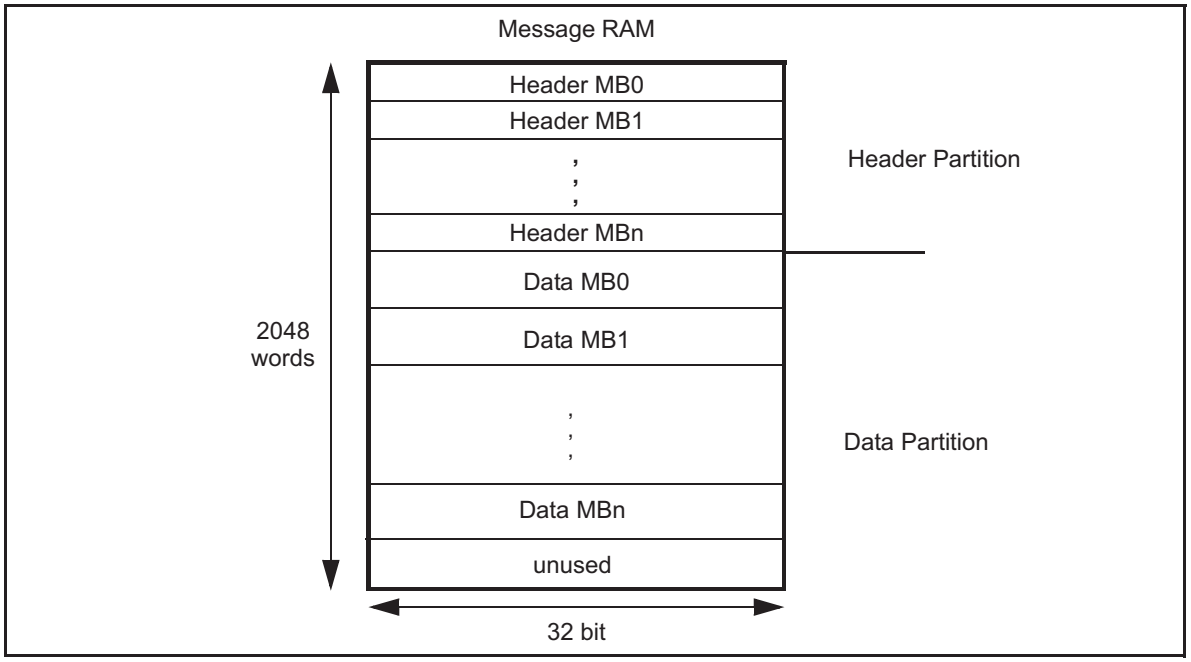
26.2.13 Module RAMs

The FlexRay module contains the following RAM portions:

- Message RAM
- Transient Buffer RAM Channel A (TBF A)
- Transient Buffer RAM Channel B (TBF B)
- Input Buffer (IBF)
- Input Buffer Shadow (IBFS)
- Output Buffer (OBF)
- Output Buffer Shadow (OBFS)
- Transfer Configuration RAM (TCR)

All RAMs except the TCR are part of the Communication Controller core.

26.2.13.1 Message RAM



To avoid conflicts between host access to the message RAM and FlexRay message reception / transmission, the host CPU cannot directly access the message buffers in the message RAM. These accesses are handled through the input and output buffers. The message RAM is able to store up to 128 message buffers depending on the configured payload length.

The message RAM has a structure as shown in Figure 26-23.

The data partition is allowed to start at Message RAM word number: (MRC.LCB + 1) • 4

Copyright © 2018, Texas Instruments Incorporated

Figure 26-23. Configuration Example of Message Buffers in the Message RAM

Header Partition

Stores header segments of FlexRay frames:

- Supports a maximum of 128 message buffers
- Each message buffer has a header of four 32 bit words
- Header 3 of each message buffer holds the 11-bit data pointer to the corresponding data section in the data partition

Data Partition

Flexible storage of data sections with different length. Some maximum values are:

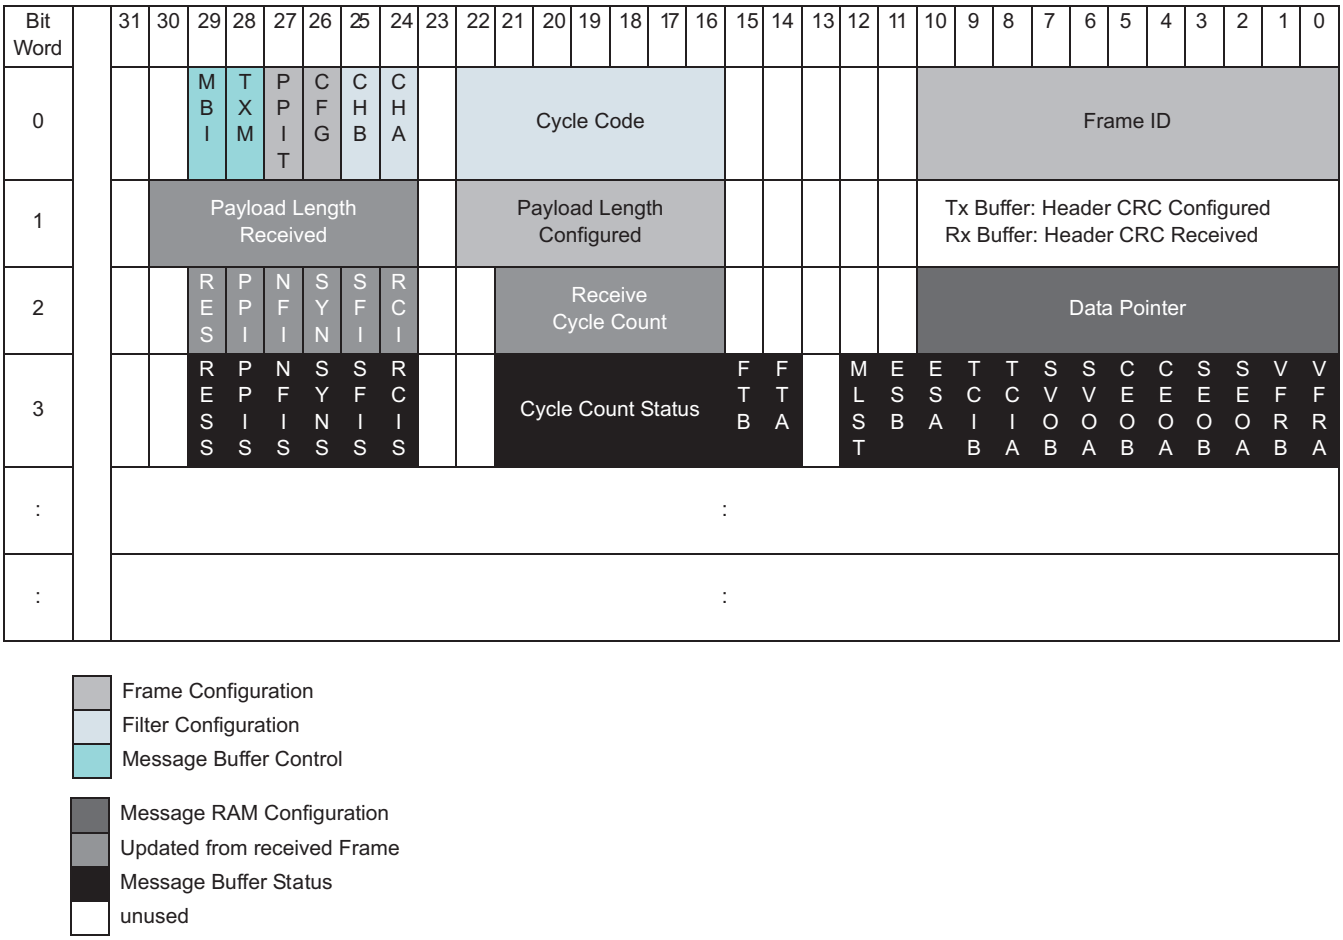
- 30 message buffers with 254 byte data section each
- Or 56 message buffers with 128 byte data section each
- Or 128 message buffers with 48 byte data section each

Restriction: header partition + data partition may not occupy more than 2048 x 32 bit words.

26.2.13.1.1 Header Partition

The elements used for configuration of a message buffer as well as the current message buffer status are stored in the header partition of the message RAM as shown in Figure 26-24. Configuration of the header sections of the message buffers is done through IBF (Write Header Section 1,2,3). Read access to the header sections is done through OBF (read header section 1,2,3 + message buffer status). The data pointer has to be calculated by the programmer to define the starting point of the data section for the corresponding message buffer in the data partition of the message RAM. The data pointer should not be modified during runtime. For message buffers belonging to the receive FIFO (re)configuration should be done in DEFAULT_CONFIG or CONFIG state only.

The header section of each message buffer occupies four 32 bit words in the header partition of the message RAM. The header of message buffer 0 starts with the first word in the message RAM.



For transmit buffers the Header CRC has to be calculated by the host CPU.

Copyright © 2018, Texas Instruments Incorporated

Payload length received (PLR(6-0)), receive cycle count (RCC(5-0)), Received on Channel Indication (RCI), Startup Frame Indication bit (SFI), sync bit (SYN), null frame indication bit (NFI), payload preamble indication bit (PPI), and reserved bit (RES) are only updated from received valid data frames only.

Header word 3 of each configured message buffer holds the corresponding message buffer status MBS.

Figure 26-24. Header Section of Message Buffer in Message RAM

Header 1 (Word 0)

Write access through WRHS1, read access through RDHS1:

- Frame ID- Slot counter filtering configuration
- Cycle Code- Cycle counter filtering configuration
- CHA, CHB- Channel filtering configuration
- CFG- Message buffer configuration: receive / transmit
- PPIT- Payload Preamble Indicator Transmit
- TXM- Transmit mode configuration: single-shot / continuous
- MBI- Message buffer receive / transmit interrupt enable

Copyright © 2018, Texas Instruments Incorporated

Header 2 (Word 1)

Write access through WRHS2, read access through RDHS2:

- Header CRC Transmit Buffer: Configured by the host (calculated from frame header)
  - Receive Buffer: Updated from received frame
- Payload Length Configured: Length of data section (2-byte words) as configured by the host
- Payload Length Received: Length of payload segment (2-byte words) stored from received frame

Header 3 (Word 2)

Write access through WRHS3, read access through RDHS3:

- Data Pointer- Pointer to the beginning of the corresponding data section in the data partition

Read access through RDHS3, valid for receive buffers only, updated from received frames:

- Receive Cycle Count - Cycle count from received frame
- RCI- Received on Channel Indicator
- SFI- Startup Frame Indicator
- SYN- Sync Frame Indicator
- NFI- Null Frame Indicator
- PPI- Payload Preamble Indicator
- RES- REServed bit

Message Buffer Status MBS (Word 3)

Read access through MBS, updated by the communication controller at the end of the configured slot.

- VFRA- Valid Frame received on channel A
- VFRB- Valid Frame received on channel B
- SEOA- Syntax Error Observed on channel A
- SEOB- Syntax Error Observed on channel B
- CEOA- Content Error Observed on channel A
- CEOB- Content Error Observed on channel B
- SVOA- Slot Boundary Violation Observed on channel A
- SVOB- Slot Boundary Violation Observed on channel B
- TCIA- Transmission Conflict Indication channel A
- TCIB- Transmission Conflict Indication channel B
- ESA- Empty Slot Channel A
- ESB- Empty Slot Channel B
- MLST- Message Lost
- FTA- Frame Transmitted on Channel A
- FTB- Frame Transmitted on Channel B
- Cycle Count Status- Current cycle count when status was updated
- RCIS- Received on Channel Indicator Status
- SFIS- Startup Frame Indication Status
- SYNS- Sync Frame Indicator Status
- NFIS- Null Frame Indicator Status
- PPIS- Payload Preamble Indicator Status
- RESS- Reserved Bit Status

Copyright © 2018, Texas Instruments Incorporated

26.2.13.1.2 Data Partition

The data partition of the message RAM stores the data sections of the message buffers configured for reception / transmission as defined in the header partition. The number of data bytes for each message buffer can vary from 0 to 254. In order to optimize the data transfer between the shift registers of the two FlexRay protocol controllers and the message RAM as well as between the host interface and the message RAM, the physical width of the message RAM is word wise (4 bytes).

The data partition starts right after the last word of the header partition. When configuring the message buffers in the message RAM the programmer has to assure that the data pointers point to addresses within the data partition.

Figure 26-25 shows an example how the payload of the configured message buffers can be stored in the data partition of the message RAM. Message buffers 0 to 2 are static buffers with a payload of 3, whereas message buffers 3 to n are dynamic buffers with variable payload.

The beginning of a message buffer's data section is determined by the data pointer and the payload length configured in the message buffer's header section. This enables a flexible usage of the available RAM space for storage of message buffers with different data lengths.

The storage of the payload data is word aligned. If the size of a message buffer payload is an odd number of 2-byte words, the remaining 16 bits in the last 32-bit word are unused (see Figure 26-25).

Figure 26-25. Example Structure of Data Partition in Message RAM

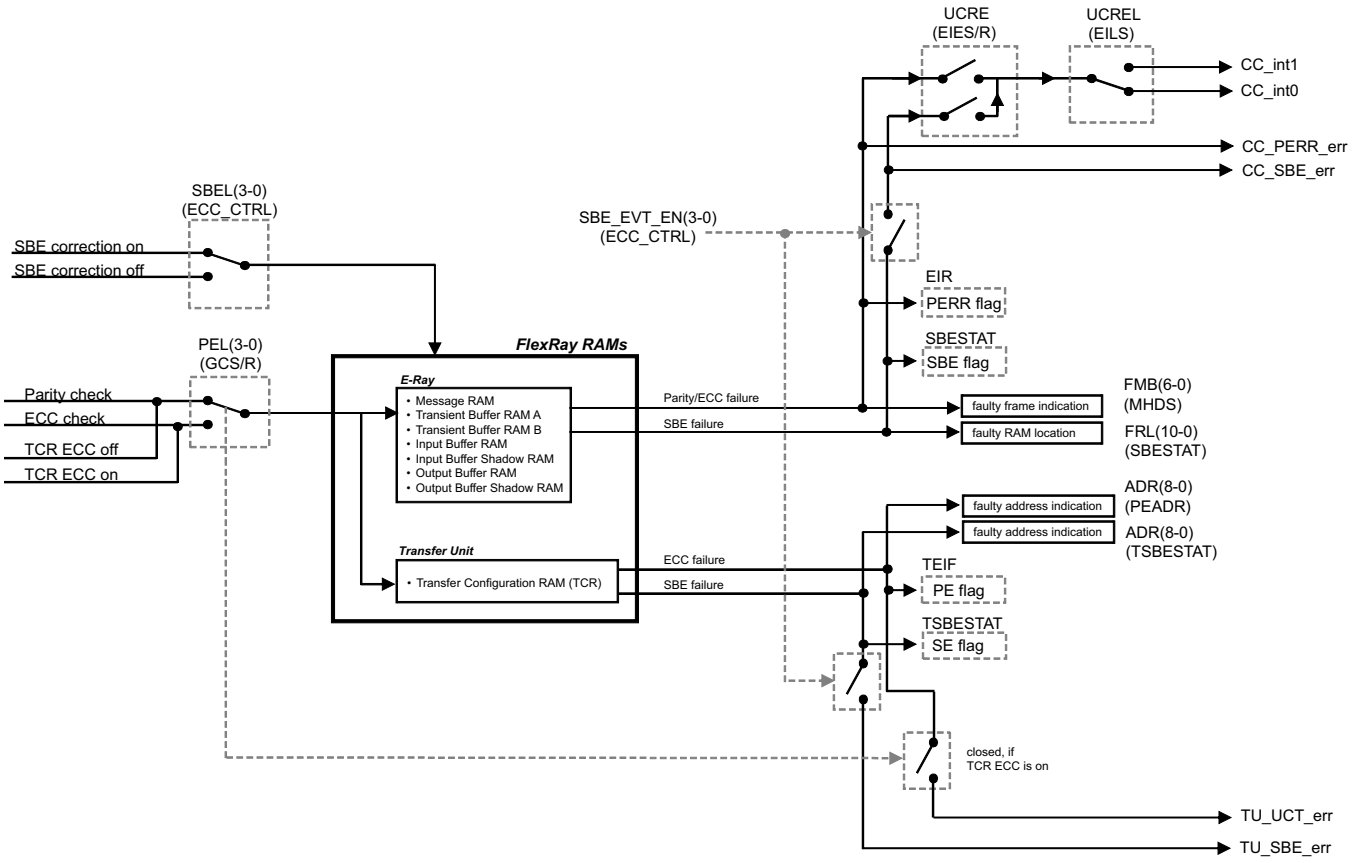
26.2.13.2 ECC Check



In order to assure the integrity of the data stored in the different RAM blocks of the module (message RAM, 2 transient buffer RAMs, 2 input buffer RAMs, 2 output buffer RAMs, Transfer Configuration RAM), the FlexRay module RAMs are optionally ECC protected.

The ECC protection is switched off by default and ECC protection is activated by writing a 4 bit key to the dedicated ECC lock bits (PEL(3-0)) in the Global Control Register (GCS/R) of the Transfer Unit register frame. ECC single-bit error correction is enabled by default and can be disabled by the 4-bit key bits SBEL in the ECC Control Register (ECC_CTRL). Only the Transfer Configuration RAM has the exceptional functionality that ECC protection can either be switched on or off by PEL(3-0). By default the ECC protection is switched off and the TCR is not protected.

Figure 26-26 shows the ECC structure concerning enabling/disabling and error indication.

Copyright © 2018, Texas Instruments Incorporated

Figure 26-26. Parity/ECC Structure

NOTE: There is no parity protection for FlexRay RAM blocks.

For the seven RAM blocks of the Communication Controller portion (message RAM, 2 transient buffer RAMs, 2 input buffer RAMs and 2 output buffer RAMs), ECC protection is added, which can be selected by the ECC lock bits (PEL(3-0)). ECC protection can not be switched off completely. For the TCR of the Transfer Unit, actually the ECC multi-bit error generation will be switched on and off by the ECC lock bits, the ECC generation itself remains always on.

ECC should be activated before initializing all RAMs by the CLEAR_RAMS command and should not be switched off during FlexRay usage.

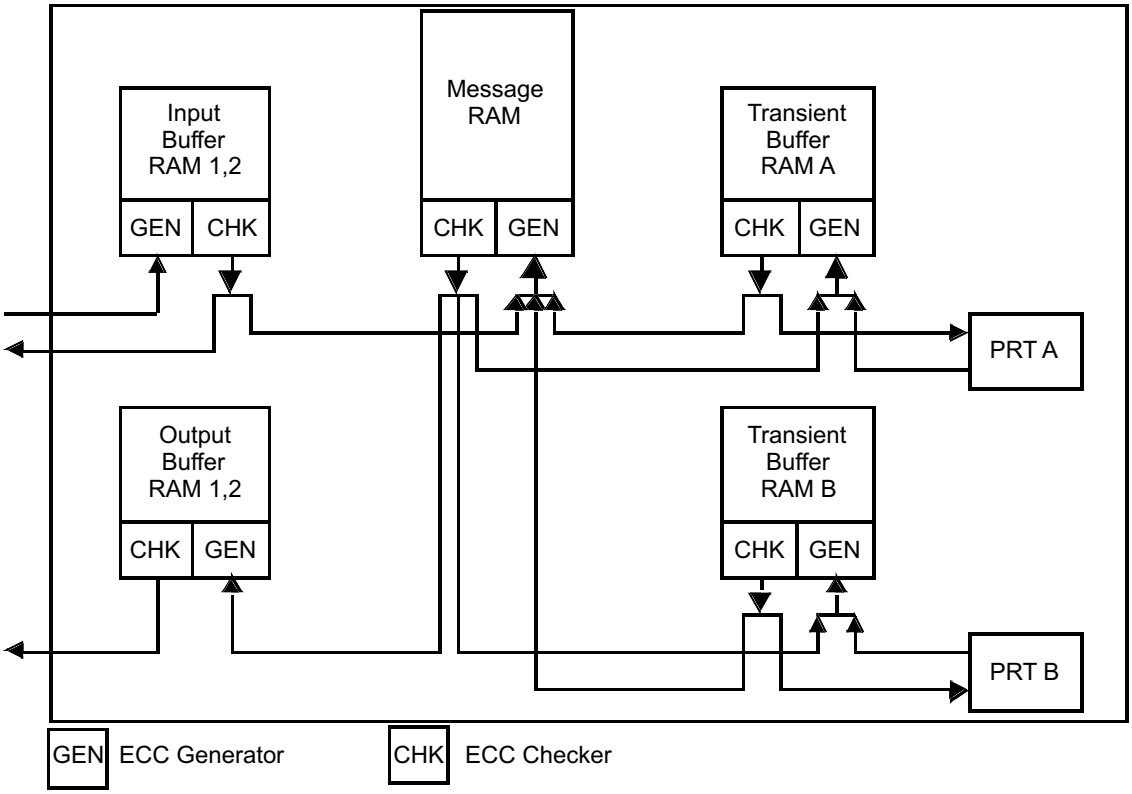
The following paragraphs describe the protection for the Communication Controller related RAM blocks. For details about the protection of the Transfer Configuration RAM (TCR) of the Transfer Unit, see Section 26.2.1.1.2.1.

All the Communication Controller related RAM blocks have an ECC generator and an ECC checker attached as shown in Figure 26-27. When data is written to a RAM block, the local ECC generator generates the corresponding ECC information.

The ECC protection supports single-bit error correction and double-bit error detection mechanism (SECDED). The ECC information is stored together with the corresponding data word.

The ECC is checked each time a data word is read from any of the RAM blocks. The module internal data buses have a width of 32 bits. If an ECC multi-bit error is detected, the PERR error flag is set in the error interrupt register (EIR). Additionally, the correction of an ECC single-bit error will be indicated by the SBE flag in the Single-Bit Error Status Register (SBESTAT).

Copyright © 2018, Texas Instruments Incorporated



An uncorrectable RAM error interrupt can be generated, if enabled by the UCRE bit in the error interrupt enable register (EIES/R). For ECC single-bit error, the uncorrectable RAM error interrupt is only generated, if the ECC single-bit error correction is disabled and the single-bit error indication key (SBE_EVT_EN in ECC_CTRL) is enabled. When single-bit error correction is turned off, the ECC algorithm will detect up to 3 bits in error in a word.

For ECC multi-bit errors the faulty message buffer number, together with the information of the failing RAM, can be read from the message handler status (MHDS) register. Equivalent information is available for ECC single-bit errors in the single-bit error location (SBESTAT) register, irrespective of ECC single-bit error correction being enabled.

Figure 26-27 shows the data paths between the RAM blocks and the ECC generators and checkers.

The ECC generation is done according to the ECC syndrome tables as shown in Figure 26-28 and Figure 26-29.

Figure 26-27. ECC Generation and Check

NOTE: The ECC generator and ECC checker are not part of the RAM blocks, but of the RAM access logic.

When an ECC error has been detected the following actions will be performed:

In all cases:

- The corresponding error flag in the message handler status (MHDS) register is set and the faulty message buffer is indicated. On ECC single-bit error equivalent information is available in the single-bit error location (SBESTAT) register.
- The error flag EIR.PERR in the error interrupt register is set and, if enabled, a module interrupt to the CPU will be generated. An ECC single-bit error is indicated by the SBESTAT.SBE flag irrespective of ECC single-bit error correction being enabled. Additionally an ECC single-bit error can generate an interrupt to the CPU.

Additionally in specific cases of ECC multi-bit errors:

1. ECC multi-bit error during data transfer from input buffer RAM 1,2 ⇒ message RAM
   a. Transfer of header and/or data section and ECC multi-bit error occurs during header and/ or data section transfer to message RAM:
      - MHDS.PIBF bit is set
      - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to a faulty message buffer
      - MHDS.FMB(6-0) indicates the number of the faulty message buffer
      - Header and/or data section of the corresponding message buffer is updated
      - Transmission request for the corresponding message buffer is not set (no transfer to the FlexRay bus)
   b. Transfer of data section only and ECC multi-bit error occurs when reading header section of the corresponding message buffer from the message RAM.
      - MHDS.PMR bit is set
      - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to a faulty message buffer
      - MHDS.FMB(6-0) indicates the number of the faulty message buffer
      - The data section of the corresponding message buffer is not updated
      - Transmission request for the corresponding message buffer is not set (no transfer to the FlexRay bus)
2. ECC multi-bit error during host CPU reading input buffer RAM 1,2
   - MHDS.PIBF bit is set
3. ECC multi-bit error during scan of header sections in message RAM
   - MHDS.PMR bit is set
   - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to a faulty message buffer
   - MHDS.FMB(6-0) indicates the number of the faulty message buffer
   - Ignore message buffer (the transfer of the message buffer is skipped)
4. ECC multi-bit error during data transfer from message RAM to transient buffer RAM 1,2
   - MHDS.PMR bit is set
   - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to the faulty message buffer
   - MHDS.FMB(6-0) indicates the number of the faulty message buffer
   - Frame not transmitted, frames already in transmission are invalidated by clearing the frame CRC to 0
5. ECC multi-bit error during data transfer from transient buffer RAM 1,2 to protocol controller 1, 2
   - MHDS.PTBF1,2 bit is set
   - Frames already in transmission are invalidated by clearing the frame CRC to 0

Copyright © 2018, Texas Instruments Incorporated

6. ECC multi-bit error during data transfer from transient buffer RAM 1,2 to message RAM
   a. ECC multi-bit error when reading header section of corresponding message buffer from message RAM
      - MHDS.PMR bit is set
      - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to a faulty message buffer
      - MHDS.FMB(6-0) indicates the number of the faulty message buffer
      - The data section of the corresponding message buffer is not updated
   b. ECC multi-bit error when reading transient buffer RAM 1,2:
      - MHDS.PTBF1,2 bit is set
      - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to a faulty message buffer
      - MHDS.FMB(6-0) indicates the number of the faulty message buffer
      - The data section of the corresponding message buffer is updated
7. ECC multi-bit error during data transfer from message RAM to output buffer RAM
   - MHDS.PMR bit is set
   - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to faulty message buffer
   - MHDS.FMB(6-0) indicates the number of the faulty message buffer
   - Header and/or data section of the output buffer is updated, but should not be used by the host CPU
8. ECC multi-bit error during host CPU reading output buffer RAM 1,2
   - MHDS.POBF bit is set
9. ECC multi-bit error during data read of transient buffer RAM 1,2

   When an ECC multi-bit error occurs during the Message Handler reads a frame with network management information (PPI = 1) from the transient buffer RAM 1,2 the corresponding network management vector register NMV1,2,3 is not updated from that frame.

Additionally in specific cases of ECC single-bit errors:

1. ECC single-bit error during data transfer from input buffer RAM 1,2 ⇒ message RAM
   a. Transfer of header and/or data section and ECC single-bit error occurs during header and/or data section transfer to message RAM:
      - SBESTAT.SIBF bit is set
      - SBESTAT.FMBD bit is set to indicate that SBESTAT.FMB(6-0) points to a faulty message buffer
      - SBESTAT.FMB(6-0) indicates the number of the faulty message buffer
      - Header and/or data section of the corresponding message buffer is updated

        If ECC single-bit error correction is disabled:
        – Transmission request for the corresponding message buffer is not set (no transfer to the FlexRay bus)
   b. Transfer of data section only and ECC single-bit error occurs when reading header section of corresponding message buffer from the message RAM.
      - SBESTAT.SMR bit is set
      - SBESTAT.FMBD bit is set to indicate that SBESTAT.FMB(6-0) points to a faulty message buffer
      - SBESTAT.FMB(6-0) indicates the number of the faulty message buffer

        If ECC single-bit error correction is disabled:
        – The data section of the corresponding message buffer is not updated
        – Transmission request for the corresponding message buffer is not set (no transfer to the FlexRay bus)
2. ECC single-bit error during host CPU reading input buffer RAM 1,2
   - SBESTAT.SIBF bit is set

Copyright © 2018, Texas Instruments Incorporated

3. ECC single-bit error during scan of header sections in message RAM
   - SBESTAT.SMR bit is set
   - SBESTAT.FMBD bit is set to indicate that SBESTAT.FMB(6-0) points to a faulty message buffer
   - SBESTAT.FMB(6-0) indicates the number of the faulty message buffer

   If ECC single-bit error correction is disabled:
   - Ignore message buffer (the transfer of the message buffer is skipped)
4. ECC single-bit error during data transfer from message RAM to transient buffer RAM 1,2
   - SBESTAT.SMR bit is set
   - SBESTAT.FMBD bit is set to indicate that SBESTAT.FMB(6-0) points to the faulty message buffer
   - SBESTAT.FMB(6-0) indicates the number of the faulty message buffer

   If ECC single-bit error correction is disabled:
   - Frame not transmitted, frames already in transmission are invalidated by clearing the frame CRC to 0
5. ECC single-bit error during data transfer from transient buffer RAM 1,2 to protocol controller 1, 2
   - SBESTAT.STBF1,2 bit is set

   If ECC single-bit error correction is disabled:
   - Frames already in transmission are invalidated by setting the frame CRC to 0
6. ECC single-bit error during data transfer from transient buffer RAM 1,2 to message RAM
   a. ECC single-bit error when reading header section of corresponding message buffer from message RAM
      - SBESTAT.SMR bit is set
      - SBESTAT.FMBD bit is set to indicate that SBESTAT.FMB(6-0) points to a faulty message buffer
      - SBESTAT.FMB(6-0) indicates the number of the faulty message buffer

      If ECC single-bit error correction is disabled:
      - The data section of the corresponding message buffer is not updated

   b. ECC single-bit error when reading transient buffer RAM 1,2:
      - SBESTAT.STBF1,2 bit is set
      - SBESTAT.FMBD bit is set to indicate that SBESTAT.FMB(6-0) points to a faulty message buffer
      - SBESTAT.FMB(6-0) indicates the number of the faulty message buffer
      - The data section of the corresponding message buffer is updated
7. ECC single-bit error during data transfer from message RAM to output buffer RAM
   - SBESTAT.SMR bit is set
   - SBESTAT.FMBD bit is set to indicate that SBESTAT.FMB(6-0) points to faulty message buffer
   - SBESTAT.FMB(6-0) indicates the number of the faulty message buffer

   If ECC single-bit error correction is disabled:
   - Header and/or data section of the output buffer is updated, but should not be used by the host CPU
8. ECC single-bit error during host CPU reading output buffer RAM 1,2
   - SBESTAT.SOBF bit is set
9. ECC single-bit error during data read of transient buffer RAM 1,2, when single-bit error correction is disabled.

   When an ECC single-bit error occurs during when the Message Handler reads a frame, with network management information (PPI = 1), from the transient buffer RAM 1,2, the corresponding network management vector register NMV1,2,3 is not updated from that frame.

26.2.13.2.1 Host Handling of Uncorrectable ECC Multi-bit Errors

Uncorrectable errors caused by transient bit flips can be fixed by:

Self-healing

Uncorrectable errors located in:

- Input Buffer RAM 1,2
- Output Buffer RAM 1,2
- Data Section of Message RAM
- Transient Buffer RAM A
- Transient Buffer RAM B
- Transfer Configuration RAM (TCR)

are overwritten with the next write access to the disturbed bit(s) caused by host access or by FlexRay communication.

CLEAR_RAMS Command

When called in DEFAULT_CONFIG or CONFIG state POC command CLEAR_RAMS initializes all module-internal RAMs to 0 and the ECC bits are initialized accordingly, depending what mode is enabled.

Temporary Unlocking of Header Section

An uncorrectable error in the header section of a locked message buffer can be fixed by a transfer from the input buffer to the locked buffer header section. For this transfer, the write-access to the IBCR (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state. For that single transfer the corresponding message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by MRC.SEC(1-0), and will be updated with new data.

NOTE: In case the previous methods do not work, it is recommended to execute the PBIST test at device level to confirm a hard error in the module internal RAMs.

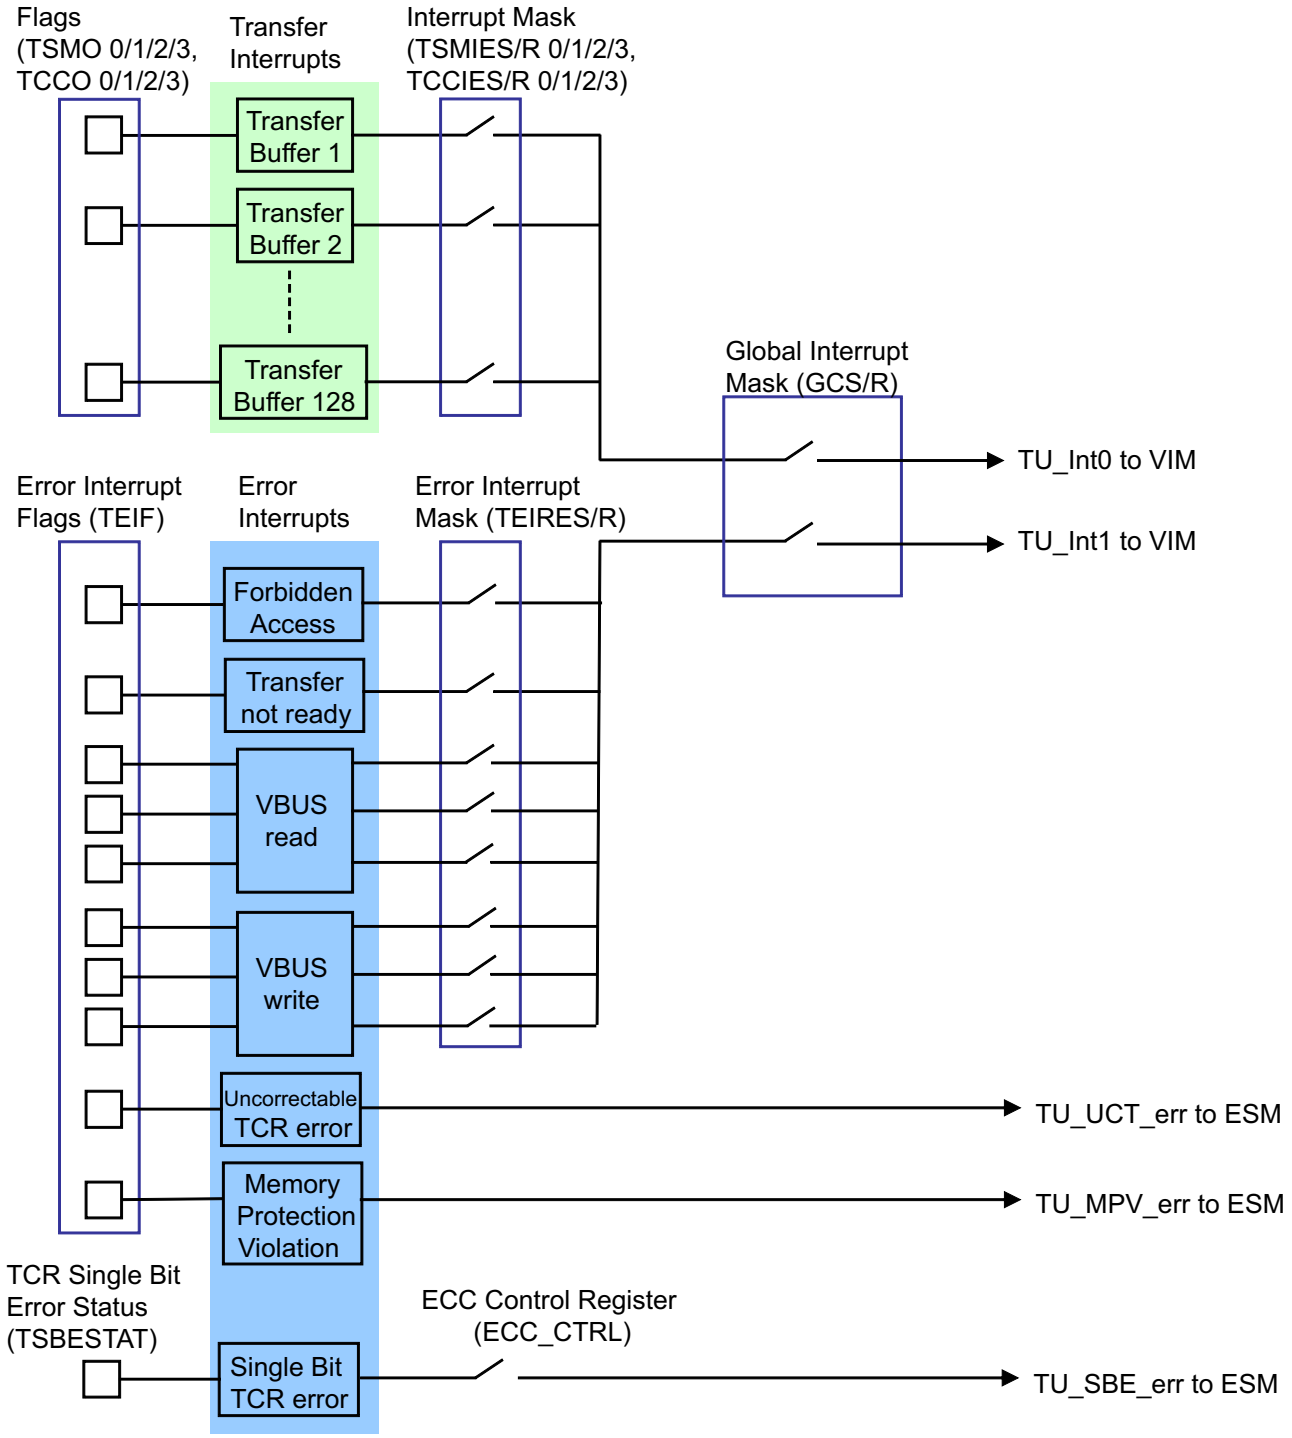
26.2.14 Interrupts

This section describes the transfer unit interrupts and the communication controller interrupts.

26.2.14.1 Transfer Unit Interrupts

26.2.14.1.1 Interrupt Structure

For transfer interrupts, one enable bit is provided for each bit in the transfer occurred status registers. Maskable error interrupts are possible for all error conditions except ECC multi-bit error and memory protection error.



The ECC multi-bit error and the memory protection error have separate non-maskable lines. Both turn off the Transfer Unit after finishing the current word access cycle.

The single-bit error interrupt is maskable. On single-bit error, if single-bit error correction is turned off, the Transfer Unit is turned off after finishing the current word access cycle.

Figure 26-30 shows the interrupt structure of the FlexRay Transfer Unit.

Copyright © 2018, Texas Instruments Incorporated

Figure 26-30. Transfer Unit (TU) Interrupt Structure

Copyright © 2018, Texas Instruments Incorporated

26.2.14.1.2 Enable Interrupts

TSMIES/R and TCCIES/R control the buffer transfer interrupts for each buffer in both directions. The TEIRES/R registers controls the maskable error interrupt sources which are:

- VBUS transaction errors

  If an error occurs during VBUS read or write transfer a error interrupt will be generated.
- Forbidden access to IBF or OBF

  Since host accesses to communication controller through the IBF and the OBF (0x400-0x7FF) are forbidden, as long as the Transfer Unit State Machine is enabled, accesses will be ignored and an error interrupt will be generated.
- Transfer not ready when TBA should be loaded

  When a transfer is ongoing/pending during base address reload on FlexRay communication cycle start (only occurs if NTBA != TBA) the TBA will not be loaded and an error interrupt will be generated.

The transfer interrupts use a separate interrupt line (TU_int0) than the error interrupts (TU_int1).

26.2.14.1.3 Interrupt Flags

The TSMO and TCCO flags indicate buffer transfer status interrupts whereas the TEIF flags indicate interrupt sources for maskable and non-maskable error interrupts.

The error interrupt flags are set by the Transfer Unit State Machine and can be cleared by the CPU by writing a 1. If the CPU clears the flag, while the Transfer Unit State Machine sets it at the same time, the flag remains set.

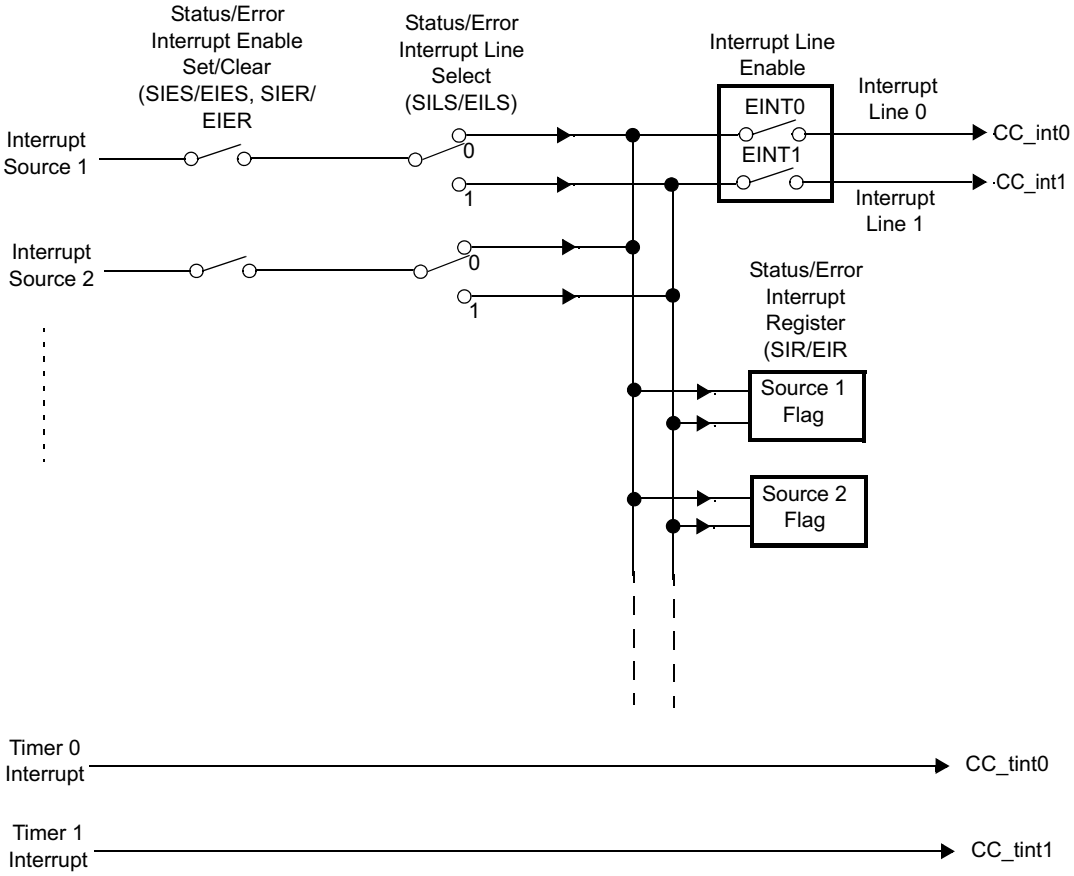
26.2.14.1.4 Nonmaskable Error Indication

Memory protection violation and uncorrectable TCR error have their own nonmaskable error lines, which can be connected to the Vectored Interrupt Module (VIM) and/or the Error Signaling Module (ESM). Refer to the device-specific data manual on the hookup.

- If a memory protection violation occurs, the Memory Protection Violation Error (TU_MPV_err) line will be activated.
- If an uncorrectable TCR error occurs while accessing the TCR, the ECC Error (TU_UCT_err) line will be activated. An uncorrectable TCR error can be caused by an ECC error in TCR.

26.2.14.2 Communication Controller Interrupts

In general, interrupts provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the controller, a frame is received or transmitted, a configured timer interrupt is activated, or a stop watch event occurred. This enables the host CPU to react very quickly on specific error conditions, status changes, or timer events. To remain flexible though, the communication controller supports disable / enable controls for each individual interrupt source separately.



An interrupt may be triggered, for example, when:

- a frame is received or transmitted
- an error was detected
- a status flag is set
- a timer reaches a preconfigured value
- a message transfer from input buffer to message RAM or from message RAM to output buffer has completed
- a stop watch event occurred

NOTE: For specific information about error interrupt generation on uncorrectable RAM errors, see Figure 26-30.

Copyright © 2018, Texas Instruments Incorporated

Figure 26-31. Communication Controller (CC) Interrupt Structure

Tracking status and generating interrupts when a status change or an error occurs are two independent tasks. Independent of an interrupt being enabled, the corresponding status is tracked and indicated by the Communication Controller. The host has access to the current status and error information by reading the error interrupt register and the status interrupt register.

The interrupt lines to the host, CC_int0 and CC_int1, are controlled by the enabled interrupts. In addition each of the two interrupt lines to the host CPU can be enabled / disabled separately by programming bit EINT0 and EINT1 in the Interrupt Line Enable register.

The two timer interrupts generated by interrupt timer 0 and 1 are available on pins CC_tint0 and CC_tint1. They can be configured via the timer 0 and timer 1 configuration register.

When a transfer between IBF / OBF and the Message RAM has completed bit SIR.TIBC or SIR.TOBC is set.

Table 26-16. Module Interrupt Flags and Interrupt Line Enable

Register	Bit	Function
EIR	PEMC	Protocol error Mode Changed
	CNA	Command Not Valid
	SFBM	Sync Frames Below Minimum
	SFO	Sync Frame Overflow
	CCF	Clock Correction Failure
	CCL	CHI Command Locked
	PERR	ECC Error
	RFO	Receive FIFO Overrun
	EFA	Empty FIFO Access
	IIBA	Illegal Input Buffer Access
	IOBA	Illegal Output Buffer Access
	MHF	Message Handler Constraints Flag
	EDA	Error Detected on Channel A
	LTVA	Latest Transmit Violation Channel A
	TABA	Transmission Across Boundary Channel A
	EDB	Error Detected on Channel B
	LTVB	Latest Transmit Violation Channel B
	TABB	Transmission Across Boundary Channel B
SIR	WST	Wakeup Status
	CAS	Collision Avoidance Symbol
	CYCS	Cycle Start Interrupt
	TXI	Transmit Interrupt
	RXI	Receive Interrupt
	RFNE	Receive FIFO not Empty
	RFCL	Receive FIFO Critical Level
	NMVC	Network Management Vector Changed
	TI0	Timer Interrupt 0
	TI1	Timer Interrupt 1
	TIBC	Transfer Input Buffer Completed
	TOBC	Transfer Output Buffer Completed
	SWE	Stop Watch Event
	SUCS	Startup Completed Successfully
	MBSI	Message Buffer Status Interrupt
	SDS	Start of Dynamic Segment
	WUPA	Wakeup Pattern Channel A
	MTSA	MTS Received on Channel A
	WUPB	Wakeup Pattern Channel B
	MTSB	MTS Received on Channel B
ILE	EINT0	Enable Interrupt Line 0
	EINT1	Enable Interrupt Line 1

26.2.15 Minimum Peripheral Clock Frequency

In order to calculate the minimum peripheral clock frequency (VBUSclk) the worst case scenario has to be considered. The worst case scenario depends on the following parameters:

- maximum payload length
- minimum minislot length
- number of configured message buffers (excluding FIFO)
- used channels (single/dual channel)

Worst case scenario:

- reception of a message with a maximum payload length in slot n (n is 7,15,23,31,39,...)
- slot n+1 to n+7 are empty dynamic slots (minislot) and configured as receive buffer
- the find-sequence (usually started in slot 8,16,24,32,40,...) has to scan the maximum number of configured buffers
- the number of concurrent tasks has its maximum value of 3

The find-sequence is executed each 8 slots (slot 8,16,24,32,40,...). It has to be finished until the next find-sequence is requested.

The duration of a Transient Buffer RAM (TBF) transfer to the Message Buffer RAM (MBF) varies from 4 (header section only) to 68 (header + maximum data section) time steps plus a setup time of 6 time steps.

$VBUScycles_{t2m}$ = (number of concurrent tasks) x (6 + (number of 4-byte words))

A Slot Status (SS) transfer to the Message Buffer RAM (MBF) has a length of 1 time step plus a setup time of 4 time steps.

$VBUSclk_{ss2m}$ = (number of concurrent tasks) x 5

The find sequence has a maximum length of 128 (maximum number of buffers) time steps plus a setup time of 2 time steps.

$VBUSclk_{find}$ = (number of concurrent tasks) x (2 + (number of configured buffers))

A minislot has a length of 2 to 63 macroticks (MTicks). The minimum nominal macrotick period (MTcycle) is 1µs. A sequence of 8 minislots has a length of

$t_{8minislots}$ = 8 x MTicks x MTcycle

The worst case VCLK cycle period can be calculated as follows:

$$t_{8\min islots} \geq \frac{VBUScycles_{t2m} + \left(7 \times VBUScycles_{ss2m}\right) + VBUScycles_{find}}{VBUSclk} \quad (32)$$

$$\frac{1}{VBUS_{clk}} \leq \frac{t_{8\min islots}}{VBUScycle_{t2m} + \left(7 \times VBUScycle_{ss2m}\right) + VBUScycle_{find}}[\mu s] \quad (33)$$

minimum $t_{8minislots}$ = 8 * 2 * 1 µs = 16 µs

maximum $VBUScycle_{t2m}$ = 3 * (6 + 68) = 222

maximum $VBUScycle_{ss2m}$ = 3 * 5 = 15

maximum $VBUScycle_{find}$ = 3 * (2 + 128) = 390

$$\frac{1}{VBUSclk} \leq = \frac{16\mu s}{222 + 7 \times 15 + 390} = 22.32ns \quad (34)$$

The minimum peripheral clock frequency for this worst case scenario is 44,8125 MHz.

pExternRateCorrection	GTUC11.ERC(2-0)

26.2.17 Emulation/Debug Support

For any debug transactions on the bus interface (VBUSP or OCP), the responses are normal except for the following:

1. Reads will not clear “read-clear” type of bits during the same.
2. User mode writes are allowed to "privilege mode write only" bits as well.

26.3 FlexRay Module Registers

26.3.1 Transfer Unit Registers

Table 26-18 provides a summary of the registers. All registers are organized as 32-bit registers. 8-, 16-, and 32-bit accesses are supported. For FlexRayTU transfers only, 4 × 32-bit data packages are supported. The base address for the Transfer Unit registers is FFF7 A000h.

The Transfer Unit State Machine registers use the offset address range 00h to 1FCh.

Transfer Configuration RAM uses the offset address range 00h to 1FCh in normal mode and 00h to 3FCh in ECC test mode.

Table 26-18. Transfer Unit Registers

Offset Address	Acronym	Register Description	Section
000h	GSN0	Global Static Number 0	Section 26.3.1.1
004h	GSN1	Global Static Number 1	Section 26.3.1.2

26.3.1.3 Global Control Set/Reset (GCS/GCR)

The GCx Registers reflects the configuration mode and allows to configure the basic Transfer Unit behavior.

The GCx registers consist of a set register (GCS) and a reset register (GCR). Bits are set by writing 1 to GCS and reset by writing 1 to GCR. Writing a 0 has no effect. Reading from both addresses will result in the same value.

For Global Control Reset (GCR) bit descriptions, see Table 26-21.

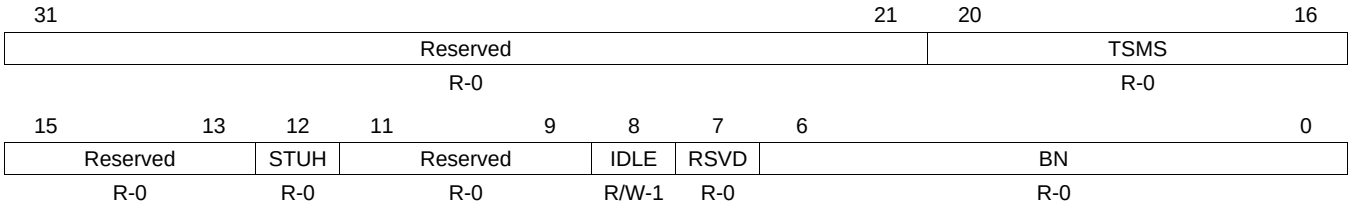
Table 26-21. Global Control Set/Reset (GCS/R) Field Descriptions

Bit	Field	Value	Description
31	ENDVBM		Endianness Correction on VBusp Master.
		0	Endianness correction switched off (Endianness is default: Little Endianness equal to Big Endian word invariant (ARM:BE-32), same as all other peripherals) (Example 32 Bit Word = ABCD).
		1	Endianness correction switched on (E-Ray Register, Header and Payload Endianness is according the configuration of bits ENDR0/1 ENDH0/1, ENDP0/1).
30	ENDVBS		Endianness correction on VBusp Slave.
		0	Endianness correction switched off (Endianness is default: Little Endianness equal to Big Endian word invariant (ARM:BE-32), same as all other peripherals) (Example 32 Bit Word = ABCD).
		1	Endianness correction switched on (E-Ray Register, Header and Payload Endianness is according the configuration of bits ENDR0/1, ENDH0/1, ENDP0/1).
29-28	ENDR		Endianness Correction for No (header or payload) Data Sink Access.
			Byte-order control of CPU access to E-Ray register, Transfer Unit register and Transfer Unit ram data. Data transferred between CPU and data sink will be corrected.
		0	Remapped to ABCDh.
		1h	Remapped to BADCh.
		2h	Remapped to CDABh.
		3h	Remapped to DCBAh.
27-26	ENDH		Endianness Correction for Header.
		0	Remapped to ABCDh.
		1h	Remapped to BADCh.
		2h	Remapped to CDABh.
		3h	Remapped to DCBAh.
25-24	ENDP		Endianness Correction for Payload.
		0	Remapped to ABCDh.
		1h	Remapped to BADCh.
		2h	Remapped to CDABh.
		3h	Remapped to DCBAh.
23-22	Reserved	0	Reads return 0. Writes have no effect.
21	PRIO		Transfer Priority.
		0	TTSM gets higher priority than TTCC.
		1	TTCC gets higher priority than TTSM.
20	Reserved	0	Reserved
19-16	PEL		ECC Lock.
		5h	ECC interrupt generation for TCR is switched off. ECC protection for message RAM, transient buffer RAMs, input buffer RAMs and output buffer RAMs is switched off.
		Others	ECC interrupt generation for TCR is switched on. ECC protection for message RAM, transient buffer RAMs, input buffer RAMs and output buffer RAMs is switched on.
			Note: For TCR, PEL enables or disables the ECC multi-bit error interrupt generation. While the ECC feature is disabled, the ECC generation is still ongoing and the error indication by the ECC interrupt flag (PE) in the Transfer Error Interrupt Flag register (TEIF) remains active. Only the ECC interrupt generation gets disabled.
15	Reserved	0	Reads return 0. Writes have no effect.
14	CETESM		Clear ETESM Register.
			Clear all bits of Enable Transfer on Event to System Memory register.
		0	Do not clear the register.
		1	Clear the register when bit is set from 0 to 1.
13	CTTCC		Clear TTCC Register.
		0	Do not clear the register.
		1	Clear the register when bit is set from 0 to 1.

Copyright © 2018, Texas Instruments Incorporated

Table 26-21. Global Control Set/Reset (GCS/R) Field Descriptions (continued)



Bit	Field	Value	Description
12	CTTSM		Clear TTSM Register.
		0	Do not clear the register.
		1	Clear the register when bit is set from 0 to 1.
11-9	Reserved	0	Reads return 0. Writes have no effect.
8	ETSM		Enable Transfer Status Mirrored.
			Mirror technique must be adjustable.
		0	Disable mirror function for TSCB, LTBCC, LTBSM, TSMO1-4, TCCO1-4, and TOOFF.
		1	Enable mirror function for TSCB, LTBCC, LTBSM, TSMO1-4, TCCO1-4, and TOOFF.
7-6	Reserved	0	Reads return 0. Writes have no effect.
5	SILE		Status Interrupt Line Enable.
			Enable status line interrupt.
		0	TU_Int0 is disabled.
		1	TU_Int0 is enabled.
4	EILE		Error Interrupt Line Enable.
			Enable error interrupt line.
		0	TU_Int1 is disabled.
		1	TU_Int1 is enabled.
3-2	Reserved	0	Reads return 0. Writes have no effect.
1	TUH		Transfer Unit Halted.
			When halted, the Transfer Unit State Machine finishes the ongoing VBUSM access before it stops working. After deassertion, the Transfer Unit State Machine continues at the point it was halted before. No reconfiguration is required.
		0	Transfer Unit is not halted.
		1	Transfer Unit is halted.
			Note: If the Transfer Unit State Machine halts, all mirroring registers contained the last transfer not the current transfer information.
0	TUE		Transfer Unit Enabled.
			Enable transfer unit.
		0	Transfer Unit is disabled, reset Transfer Unit State Machine, completion of the current VBUS transfer cycle but data could be corrupt.
		1	Transfer Unit is enabled.
			Note: Before switching on the Transfer Unit, the registers must be set up. After re-enabling of the Transfer Unit State Machine the contents of the module registers and the TCR is still valid (assuming it was continuously powered).

26.3.1.4 Transfer Status Current Buffer (TSCB)

The Transfer Status Current Buffer displays the current buffer in progress and indicates if the Transfer Unit State Machine is idle and is halt. The IDLE flag is cleared by writing a 1 to it.

Figure 26-36. Transfer Status Current Buffer (TSCB) [offset_TU = 18h]

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 26-22. Transfer Status Current Buffer (TSCB) Field Descriptions

Bit	Field	Value	Description
31-21	Reserved	0	Reads return 0. Writes have no effect.
20-16	TSMS		Transfer State Machine Status.
			Reflects the current status of the transfer state machine for debug purpose (only available in debug mode in combination with a debugger). In Normal Operation Mode, the value of TSMS is always read as 0.
		1h	IDLE state
			Transfer Trigger to System Memory:
		2h	Start state (TTSM_START)
		3h	Output Buffer Command Mask access state (TTSM_OBCM)
		4h	Request state (TTSM_REQ)
		5h	View state (TTSM_VIEW)
		6h	Check state (TTSM_CHECK)
		7h	Read Header Section access state (TTSM_RDHS)
		8h	Read Data Section access state (TTSM_RDDS)
			Transfer Trigger to Communication Controller:
		9h	Start state (TTCC_START)
		Ah	Busy state (TTCC_IBUSY)
		Bh	Check state (TTCC_CHECK)
		Ch	Write Header Section access state (TTCC_WRHS)
		Dh	Payload Read state (TTCC_PLC_READ)
		Eh	Payload Calculation state (TTCC_PLC_CALC)
		Fh	Write Data Section access state (TTCC_WRDS)
		10h	Input Buffer Command Mask access state (TTCC_IBCM)
		11h	Input Buffer Command Request access state (TTCC_IBCR)
		12h	Mirror state (TTCC_MIRROR)
		13h	End state (TTSM_END)
		14h-1Eh	Reserved
		1Fh	Undefined state
15-13	Reserved	0	Reads return 0. Writes have no effect.
12	STUH		Status of Transfer Unit State Machine for Halt Detection.
		0	Not in HALT status.
		1	In HALT status.
11-9	Reserved	0	Reads return 0. Writes have no effect.

26.3.1.7 Transfer Base Address (TBA)

The Transfer Base Address register holds a 32-bit aligned 32-bit base-pointer, which defines the base address for the data to be transferred.

NOTE: A write to this register also modifies the NTBA register.

Figure 26-39. Transfer Base Address (TBA) [offset_TU = 24h]

26.3.1.14 Transfer Occurred Offset (TOOFF)

The Transfer Occurred Offset register contains the offset vector to the highest prior pending transfer occurred interrupt and the transfer direction.

After a read access the transfer occurred flag is cleared and the register contents will be updated automatically.

Figure 26-52. Transfer Occurred Offset (TOOFF) [offset_TU = 60h]

LEGEND: R = Read only; -*n* = value after reset

Table 26-32. Transfer Occurred Offset (TOOFF) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reads return 0. Writes have no effect.
8	TDIR		Transfer Direction. In case the same interrupt occurs for communication controller and Transfer Unit State Machine transfers the PRIO bit in the Global Control register decides about the higher priority.
		0	A transfer to System Memory occurred.
		1	A transfer to the Communication Controller occurred.
7-0	OFF		Offset Vector
		0	Offset not valid (no transfer occurred, interrupt pending).
		1h	Interrupt pending for buffer 0.
		2h	Interrupt pending for buffer 1.
		3h	Interrupt pending for buffer 2.
		:	:
		80h	Interrupt pending for buffer 127.
		81h-FFh	Reserved

26.3.1.15 TCR Single-Bit Error Status (TSBESTAT)

After an ECC single-bit error in the Transfer Configuration RAM (TCR) occurred, the SE flag is set and the affected address is stored in this register. The register is updated without regard to the ECC single-bit error correction activation in the ECC Control Register (ECC_CTRL).

The contents of this register is cleared automatically when reading the register.

NOTE: ECC single-bit error can only be indicated by the SE bit when ADR is cleared. Since the contents of ADR is undefined after reset, it is recommended to clear the register by reading it.

Figure 26-53. TCR Single-Bit Error Status (TSBESTAT) [offset_TU = 6Ch]

Table 26-33. TCR Single-Bit Error Status (TSBESTAT) Field Descriptions

Bit	Field	Value	Description
31	SE		ECC Single-Bit Error. The flag signals an ECC single-bit error to the host. The flag is set when an ECC single-bit error in TCR is detected. The flag is set without regard to the single-bit error lock setting of ECC Control Register (ECC_CTRL). ECC multi-bit errors are indicated by a separate PE bit in the Transfer Error Interrupt Flag (TEIF) register.
		0	No ECC single-bit error occurred.
		1	ECC single-bit error occurred.
30-9	Reserved	0	Reads return 0. Writes have no effect.
8-0	ADR		Address of failing TCR word location. ADR[8-2] is the TCR word address where the ECC single-bit error occurred. ADR[1-0] are always driven as 00.

Copyright © 2018, Texas Instruments Incorporated

26.3.1.16 ECC Error Address (PEADR)

After an ECC multi-bit error in the Transfer Configuration RAM occurred, the affected address is stored in this not resettable register.

The contents of the ECC Error Address register as well as the PE bit in the Transfer Error Interrupt Flag (TEIF) register is cleared automatically when reading the ECC Error Address register.

NOTE: An ECC multi-bit error can only be indicated by the PE bit of TEIF register when PEADR is cleared. Since the contents of PEADR is undefined after reset, it is recommended to clear the register by reading it.

Figure 26-54. ECC Error Address (PEADR) [offset_TU = 70h]

31-9	Reserved	0	Reads return 0. Writes have no effect.
8-0	ADR	0-1FFh	Address of failing TCR location. ADR[8-2] is the TCR word address where the ECC multi-bit error occurred. ADR[1-0] are always driven as 11.

Copyright © 2018, Texas Instruments Incorporated

26.3.1.17 Transfer Error Interrupt Flag (TEIF)

The Transfer Error Interrupt Flag register includes the Transfer Unit error flags. The bits in the TEIF are cleared by writing a 1.

NOTE: Memory Protection Violation (MPV) and ECC Error (PE) interrupts are nonmaskable and can not be disabled. Therefore, the MPV and PE bits are not part of the Transfer Error Interrupt Enable Set/Reset (TEIRES/R) registers.

Figure 26-55. Transfer Error Interrupt Flag (TEIF) [offset_TU = 74h]

26.3.1.18 Transfer Error Interrupt Enable Set/Reset (TEIRES/TEIRER)

The Transfer Error Interrupt Enable Set controls the interrupt activation of interrupt line TU_Int1. An interrupt is generated if both the interrupt flag in TEIF and the corresponding bit in TEIRES are set.

Exceptions are the memory protection violation (MPV) and the ECC (PE) error, which are related to nonmaskable interrupts, and therefore are not part of the TEIRS/R registers. Those errors have private error lines (TU_MPV_err and TU_UCT_err), which can be connected to the Vectored Interrupt Module (VIM) and/or the Error Signaling Module (ESM). Refer to the device-specific data manual for more details about the signal hookup.

A Transfer Error Interrupt is enabled by writing 1 to TEIRES register and disabled by writing 1 to TIERER register. Writing of 0 has no effect. Reading from both addresses will result in the same value.

26.3.1.19 Trigger Transfer to System Memory Set/Reset (TTSMS[1-4]/TTSMR[1-4])

The Trigger Transfer to System Memory register selects the current message buffer for a Transfer Unit State Machine transfer transaction to system memory. Four 32-bit registers reflect all possible 128 message buffers.

The bits are set by writing 1 to TTSMSx and reset by writing 1 to TTSMRx or after the transfer occurred. Writing a 0 has no effect. Reading from both addresses will result in the same value.

26.3.1.23 Transfer to System Memory Interrupt Enable Set/Reset (TSMIES[1-4]/TSMIER[1-4])

The Transfer to System Memory Interrupt Enable registers enable the interrupt generation on interrupt line TU_Int0, after a transfer to the system memory occurred (flagged in TSMO). Four 32-bit Registers reflect all 128 MB's.

The bits are set by writing 1 to TSMIESx and reset by writing 1 to TSMIERx. Writing a 0 has no effect. Reading from both addresses will result in the same value.

26.3.1.25 Transfer Configuration RAM (TCR)

The TCR consists of 128 entries, each 19 bit wide. The TCR is ECC protected. The ECC protection can be switched on or off by the 4-bit key (PEL(3-0)) in the Global Control Set/Reset (GCS/R) registers.

Figure 26-106. Transfer Configuration RAM (TCR) [offset_TU_RAM = 0000h - 01FFh]

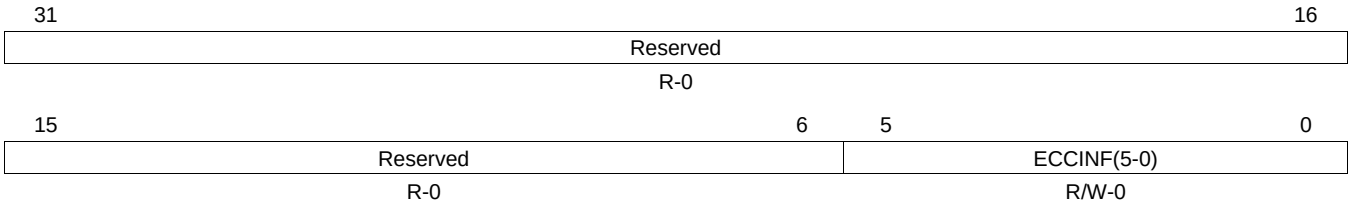
LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-86. Transfer Configuration RAM (TCR) Field Descriptions



Bit	Field	Value	Description
31-19	Reserved	0	Reads return 0. Writes have no effect.
18	STXR		Set Transmit Request. Control set/reset of buffer transmit requests in the communication controller.
		0	Transfer Unit State Machine will set IBCM.STXRH to 0 during a transfer to the communication controller.
		1	Transfer Unit State Machine will set IBCM.STXRH to 1 during a transfer to the communication controller.
17	THTSM		Transfer Header to System Memory.
		0	Transfer Unit State Machine will not transfer buffer header to system memory.
		1	Transfer Unit State Machine will transfer buffer header to system memory.
16	TPTSM		Transfer Payload to System Memory.
		0	Transfer Unit State Machine will not transfer buffer payload to system memory.
		1	Transfer Unit State Machine will transfer buffer payload to system memory.
15	THTCC		Transfer Header to Communication Controller.
		0	Transfer Unit State Machine will not transfer buffer header to the communication controller.
		1	Transfer Unit State Machine will transfer buffer header to the communication controller.
14	TPTCC		Transfer Payload to Communication Controller.
		0	Transfer Unit State Machine will not transfer buffer payload to the communication controller.
		1	Transfer Unit State Machine will transfer buffer payload to the communication controller.
13-0	TSO		Transfer Start Offset. 14-bit buffer address offset in system memory. The resulting address in system memory is computed by adding the 32-bit aligned buffer address offset (TSO = buffer address offset bits 15:2) to the base address defined in the TBA register. Example: A TSO contents of 0x40 results in a Transfer Start Offset of 0x40 × 4 = 0x100

26.3.1.26 TCR ECC Test Mode

In ECC test mode (diagnostic mode is enabled in ECC Control Register (ECC_CTRL)) the ECC information is visible and can be read or written. The corresponding TCR entry can be found by subtracting 0x200 from the TCR offset.

26.3.2 Communication Controller Registers

The FlexRay Communication Controller module allocates an address space of 2 Kbytes (0000h to 07FFh). The registers are organized as 32-bit registers. 8/16-bit accesses are also supported. CPU access to the message RAM is done through the input and output buffers. They buffer data to be transferred to and from the message RAM under control of the message handler, avoiding conflicts between CPU accesses and message reception / transmission. Alternatively to increase performance the Transfer Unit can be used for transferring buffer data.

The test registers located on address 0010h and 0014h are writable only under the conditions.

The assignment of the message buffers is done according to the scheme shown in Figure 26-108. The number N of available message buffers depends on the payload length of the configured message buffers. The maximum number of message buffers is 128. The maximum payload length supported is 254 bytes.

The message buffers are separated into three consecutive groups; see Figure 26-108:

- Static buffers - Transmit / receive buffers assigned to static segment
- Static + Dynamic buffers - Transmit / receive buffers assigned to static or dynamic segment
- FIFO - Receive FIFO

The message buffer separation configuration can be changed in DEFAULT_CONFIG or CONFIG state only by programming register MRC.

The first group starts with message buffer 0 and consists of static message buffers only. Message buffer 0 is dedicated to hold the startup / sync frame or the single slot frame, if the node transmits one, as configured by SUCC1.TXST, SUCC1.TXSY, and SUCC1.TSM. In addition, message buffer 1 may be used for sync frame transmission in case that sync frames or single-slot frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1 and message buffers 0 and 1 have to be configured with the key slot ID and can be (re)configured in DEFAULT_CONFIG or CONFIG state only.

The second group consists of message buffers assigned to the static or to the dynamic segment. Message buffers belonging to this group may be reconfigured during run time from dynamic to static or vice versa depending on the state of MRC.SEC.

The message buffers belonging to the third group are concatenated to a single receive FIFO.

Figure 26-108. Message Buffer Assignment

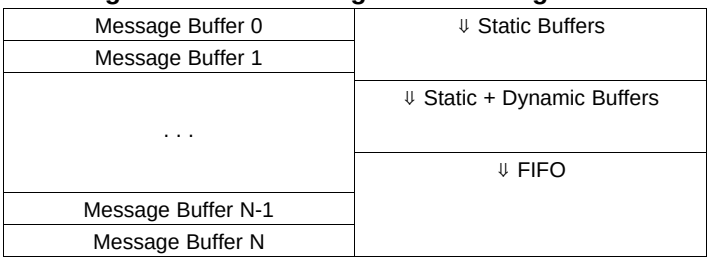

Table 26-88 provides a summary of the registers. The base address for the Communication Controller registers is FFF7 C800h.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.1 Special Registers

26.3.2.1.1 ECC Control Register (ECC_CTRL)

ECC Control Register holds three 4-bit keys. SBEL to turn ECC single-bit error correction on or off, SBE_EVT_EN to enable a single-bit error event and DIAGSEL to enable the diagnostic mode to test the ECC single-bit error correction and double-bit error detection (SECDED) mechanism. Write access to key DIAGSEL is only possible in privilege mode.

Figure 26-109 and Table 26-89 illustrate this register.

NOTE: Diagnostic mode should be used only for RAM test purpose in RAM test mode. Therefore, when entering diagnostic mode, the FlexRay module should be in RAM test mode (TMC(1-0) set to 1 in Test Register 1 (TEST1)) before performing ECC testing.

Single-bit error correction can only be active when ECC is enabled.

Figure 26-109. ECC Control Register (ECC_CTRL) [offset_CC = 00h]

31	28	27	24	23	20	19	16
Reserved		SBE_EVT_EN		Reserved		SBEL	
R-0		R/W-5h		R-0		R/W-Ah	

15	4	3	0
Reserved		DIAGSEL	
R-0		R/WP-Ah	

LEGEND: R/W = Read/Write; R = Read only; WP = Write in Privilege Mode only; -*n* = value after reset

Table 26-89. ECC Control Register (ECC_CTRL) Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Reads return 0. Writes have no effect.
27-24	SBE_EVT_EN		ECC Single-Bit Error Indication.
		5h	ECC single-bit error indication is disabled. On ECC single-bit error detection when reading from message RAM, transient buffer RAMs, input buffer RAMs and output buffer RAMs, the single-bit error event signal of the communication controller (CC_SBE_err) is activated. On ECC single-bit error detection when reading from TCR, the single-bit error event signal of the transfer unit (TU_SBE_err) is activated.
		All other values	ECC single-bit error indication is enabled. On ECC single-bit error detection when reading from message RAM, transient buffer RAMs, input buffer RAMs and output buffer RAMs, the single-bit error event signal of the communication controller (CC_SBE_err) is not activated. On ECC single-bit error detection when reading from TCR, the single-bit error event signal of the transfer unit (TU_SBE_err) is not activated.
23-20	Reserved	0	Reads return 0. Writes have no effect.
19-16	SBEL		ECC Single-Bit Error Lock.
		5h	ECC single-bit error correction is turned off. ECC single-bit errors in the FlexRay RAMs do not get corrected and the ECC algorithm will detect up to 3 bits in error in a word.
		All other values	ECC single-bit error correction is turned on. ECC single-bit errors in the FlexRay RAMs get corrected.
15-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	DIAGSEL		Diagnostic Mode select Key. The 4-bit key enables or disables the diagnostic mode.
		5h	Diagnostic mode is enabled. Double-bit errors will not trigger the peripheral ECC interrupt.
		All other values	Diagnostic mode is disabled. Double-bit errors will trigger the peripheral ECC interrupt.

26.3.2.1.2 ECC Diagnostic Status Register (ECCDSTAT)

ECC Diagnostic Status Register holds the ECC single-bit error and the double-bit error flags when in diagnostic mode. A flag is cleared by writing a 1 to it.

Figure 26-110 and Table 26-90 illustrate this register.

NOTE: In normal operation mode, double-bit errors are indicated in the Message Handler Status (MHDS) register, except for FTU RAM. A double-bit error in FTU RAM is indicated by the dedicated ECC error flag (PE) in the Transfer Error Interrupt Flag (TEIF) register.

26.3.2.1.3 ECC Test Register (ECCTEST)

The ECC Test Register can be used in diagnostic mode to read or write ECC information of message RAM, transient buffer RAM, input buffer RAM and output buffer RAM locations. Write access to this register is only possible when in diagnostic mode.

In order to be able to directly access the above mentioned RAM portions, RAM test mode must be selected in test register 1 and the corresponding RAM section must be selected in test register 2. When reading a certain RAM location, the corresponding ECC value is shown in RDECC bitfield. Writing to a certain ECC location copies the contents of WRECC bitfield to the corresponding ECC location.

Figure 26-111 and Table 26-91 illustrate this register.

NOTE: For FTU RAM, a separate portion of memory-mapped RAM is available in TCR ECC test mode, which can be accessed directly for reading or writing ECC information. See Section 26.3.1.26 for more details.

Figure 26-111. ECC Test Register (ECCTEST) [offset_CC = 08h]

26.3.2.1.4 Single-Bit Error Status Register (SBESTAT)

In normal operation mode, the Single-Bit Error Status Register indicates an ECC single-bit error by setting the SBE flag. In addition, it holds the faulty message buffer number and the indication of the buffer RAM when an ECC single-bit error occurred. The register is updated without regard to the single-bit error lock setting of ECC Control Register (ECC_CTRL).

A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. A hardware reset or CHI command CLEAR_RAMS will also clear the register.

Figure 26-112 and Table 26-92 illustrate this register.

NOTE: An ECC single-bit error in the FTU RAM (TCR) is indicated by a dedicated TCR Single-Bit Error Status (TSBESTAT) register.

When one of the flags SBEFA, SBEFB, SBEFC, SBEFD, SBEFE, SBEFF and SBEFG changes from 0 to 1, the SBE flag is set to 1.

Figure 26-112. Single-Bit Error Status Register (SBESTAT) [offset_CC = 0Ch]

31	30						16

Table 26-92. Single-Bit Error Status Register (SBESTAT) Field Descriptions

Bit	Field	Value	Description
31	SBE		ECC Single-Bit Error. The flag signals an ECC single-bit error to the host. The flag is set by the ECC logic of the communication controller, when it detects an ECC single-bit error while reading from one of the FlexRay RAM blocks. This flag is set without regard to the SBEL bit setting in the ECC Control Register (ECC_CTRL). Note: ECC multi-bit errors are indicated by a separate PERR bit in the Error Interrupt Register (EIR).
		0	No ECC single-bit error occurred.
		1	ECC single-bit error occurred.
30-15	Reserved	0	Reads return 0. Writes have no effect.
14-8	FMB	0-7Fh	Faulty message buffer. An ECC single-bit error occurred when reading from a message buffer or when transferring data from Input Buffer or Transient Buffer 1,2 to the message buffer referenced by FMB. This value is only valid when one of the flags SIBF, SMR, STBF1, STBF2, and flag FMBD is set. It is not updated while flag FMBD is set.
7	Reserved	0	Reads return 0. Writes have no effect.
6	MFMB		Multiple message buffers with ECC single-bit error fault detected.
		0	No additional faulty message buffer.
		1	Another faulty message buffer was detected while flag FMBD is set.
5	FMBD		Message buffer with ECC single-bit error fault detected.
		0	No faulty message buffer.
		1	Message buffer referenced by FMB holds faulty data due to an ECC single-bit error.
4	STBF2		ECC single-bit error in transient buffer RAM B.
		0	No ECC single-bit error.
		1	ECC single-bit error occurred when reading transient buffer RAM B.

Copyright © 2018, Texas Instruments Incorporated

Table 26-92. Single-Bit Error Status Register (SBESTAT) Field Descriptions (continued)

Bit	Field	Value	Description
3	STBF1		ECC single-bit error in transient buffer RAM A.
		0	No ECC single-bit error.
		1	ECC single-bit error occurred when reading transient buffer RAM A.
2	SMR		ECC single-bit error in message RAM.
		0	No ECC single-bit error.
		1	ECC single-bit error occurred when reading message RAM.
1	SOBF		ECC single-bit error in output buffer RAM 1, 2.
		0	No ECC single-bit error.
		1	ECC single-bit error occurred when message handler read output buffer RAM 1,2.
0	SIBF		ECC single-bit error in input buffer RAM 1, 2.
		0	No ECC single-bit error.
		1	ECC single-bit error occurred when message handler read input buffer RAM 1,2.

26.3.2.1.5 Test Register 1 (TEST1)

Test register 1 holds the control bits to configure the test modes of the FlexRay module. Write access to these bits is only possible if the WRTEN bit is set. Figure 26-113 and Table 26-93 illustrate this register.

When the FlexRay module is operated in one of its test modes that requires WRTEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available.

NOTE: To return from test mode operation to regular FlexRay operation we strongly recommend to apply a hardware reset (Power on Reset or nReset) to reset all FlexRay internal state machines to their initial state.

The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the FlexRay module. Therefore, normal operation as specified outside this chapter and as required by the FlexRay protocol specification and the FlexRay conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay protocol functions.

NOTE: The FlexRay module should be kept in CONFIG state, while RAM Test Mode TMC = 01 is enabled.

The test mode features are intended for hardware testing or for FlexRay bus analyzer tools. They are not intended to be used in FlexRay applications.

Figure 26-113. Test Register 1 (TEST1) [offset_CC = 10h]

Table 26-93. Test Register 1 (TEST1) Field Descriptions (continued)

Bit	Field	Value	Description
27-24	CERA		Coding Error Report Channel A.
			Set when a coding error is detected on channel A. Reset to 0 when register TEST1 is read or written. Once the CERA is set it will remain unchanged until the Host accesses the TEST1 register
		0	No coding error is detected.
		1h	Header CRC error is detected.
		2h	Frame CRC error is detected.
		3h	Frame Start Sequence FSS too long.
		4h	First bit of Byte Start Sequence BSS seen LOW.
		5h	Second bit of Byte Start Sequence BSS seen HIGH.
		6h	First bit of Frame End Sequence FES seen HIGH.
		7h	Second bit of Frame End Sequence FES seen LOW.
		8h	CAS / MTS symbol seen too short.
		9h	CAS / MTS symbol seen too long.
		Ah-Fh	Reserved
			Note: Coding errors are also signaled when the communication controller is in MONITOR_MODE. The error codes regarding CAS / MTS symbols concern only the monitored bit pattern, irrelevant whether those bit patterns occurred in the symbol window or elsewhere.
23-22	Reserved	0	Reads return 0. Writes have no effect.
21	TXENB		Control of channel B transmit enable pin.
		0	txen2 pin drives a 0.
		1	txen2 pin drives a 1.
20	TXENA		Control of channel A transmit enable pin.
		0	txen1 pin drives a 0.
		1	txen1 pin drives a 1.
19	TXB		Control of channel B transmit pin.
		0	txd2 pin drives a 0.
		1	txd2 pin drives a 1.
18	TXA		Control of channel A transmit pin.
		0	txd1 pin drives a 0.
		1	txd1 pin drives a 1.
17	RXB		Monitor channel B receive pin.
		0	rxd2 = 0
		1	rxd2 = 1
16	RXA		Monitor channel A receive pin.
		0	rxd1 = 0
		1	rxd1 = 1
15-10	Reserved	0	Reads return 0. Writes have no effect.
9	AOB		Activity on B. The channel idle condition is specified in the FlexRay protocol spec v2.1, BITSTRB process.
		0	No activity is detected, channel B is idle.
		1	Activity is detected, channel B is not idle.
8	AOA		Activity on A. The channel idle condition is specified in the FlexRay protocol spec v2.1, BITSTRB process.
		0	No activity is detected, channel A is idle.
		1	Activity is detected, channel A is not idle.
7-6	Reserved	0	Reads return 0. Writes have no effect.

Copyright © 2018, Texas Instruments Incorporated

Table 26-93. Test Register 1 (TEST1) Field Descriptions (continued)

Bit	Field	Value	Description
5-4	TMC		Test mode control.
		0	Normal operation mode, default.
		1h	RAM test mode. All RAM blocks of the FlexRay module are directly accessible by the host. This mode is intended to enable testing of the embedded RAM blocks during production testing.
		2h	I/O test mode. The output pins txd1, txd2, txen1, txen2 are driven to the values defined by bits TXA, TXB, TXENA, TXENB. The values applied to the input pins rxd1, rxd2 can be read from register bits RXA, RXB.
		3h	Unused. Mapped to normal operation mode.
3-2	Reserved	0	Reads return 0. Writes have no effect.
1	ELBE		External Loop Back Enable. There are two possibilities to perform a loop back test. External loop back via physical layer or internal loop back for in-system self-test (default). In case of an internal loop back pins txen1,2 are in their inactive state, pins txd1,2 are set to HIGH, pins rxd1,2 are not evaluated. Bit ELBE is evaluated only when POC is in loop back mode and test mode control is in normal operation mode TMC = 00.
		0	Internal loop back (default).
		1	External loop back.
0	WRTEN		Write test register enable. Enables write access to the test registers. To set the bit from 0 to 1, the test mode key has to be written as defined in Lock Register (LCK). The unlock sequence is not required when WRTEN is kept at 1 while other bits of the register are changed. The bit can be reset to 0 at any time.
		0	Write access to the test register is disabled.
		1	Write access to the test register is enabled.

26.3.2.1.5.1 Asynchronous Transmit Mode (ATM)

The asynchronous transmit mode is entered by writing 1110 to the controller host interface command vector CMD in the SUC configuration register 1 (controller host interface command: ATM) while the communication controller is in CONFIG state and bit WRTEN in the test register 1 is set to 1. When called in any other state or when bit WRTEN is not set, CMD will be reset to 0000 = command_not_accepted. POCS in the communication controller status vector will show 00 1110 while the FlexRay module is in ATM mode.

Asynchronous transmit mode can be left by writing 0001 (controller host interface command: CONFIG) to the controller host interface command vector CMD in the SUC configuration register 1.

In ATM mode transmission of a FlexRay frame is triggered by writing the number of the corresponding message buffer to the input buffer command request register while bit STXR in the input buffer command mask register is set to 1. In this mode wakeup, startup, and clock synchronization are bypassed, the controller host interface command SEND_MTS results in the immediate transmission of a MTS symbol.

MTS symbols received while operating in ATM mode will set the status interrupt flags MTSA,B in the Status Interrupt Register like in monitor mode.

26.3.2.1.5.2 Loop Back Mode

The loop back mode is entered by writing 1111 to the controller host interface command vector CMD(3-0) in the SUC configuration register 1 (controller host interface command: LOOP_BACK) while the communication controller is in CONFIG state and bit WRTEN in the test register 1 is set to 1. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit WRTEN is not set, CMD will be reset to 0000 = command_not_accepted. POCS in the communication controller status vector will show 00 1101 while the FlexRay module is in loop back mode.

Loop back mode can be left by writing 0001 (controller host interface command: CONFIG) to the controller host interface command vector CMD in the SUC configuration register 1.

Copyright © 2018, Texas Instruments Incorporated

The loop back mode is intended to check the modules internal data paths. Normal, time triggered operation is not possible in loop back mode.

There are two possibilities to perform a loop back test. External loop back through the physical layer (TEST1.ELBE = 1) or internal loop back for in-system self-test (TEST1.ELBE = 0). In case of an internal loop back pins txen1,2_n are in their inactive state, pins txd1,2 are set, pins rxd1,2 are not evaluated.

When the communication controller is in loop back mode, a loop back test is started by the host writing a message to the input buffer and requesting the transmission by writing to the input buffer command request register. The message handler will transfer the message into the message RAM and then into the transient buffer of the selected channel. The channel protocol controller (PRT) will read (in 32-bit words) the message from the transmit part of the transient buffer and load it into its Rx / Tx shift register. The serial transmission is looped back into the shift register; its content is written into the receive part of the channels transient buffer before the next word is loaded.

The PRT and the message handler will then treat this transmitted message like a received message, perform an acceptance filtering on frame ID and receive channel, and store the message into the message RAM (assuming the message passed the acceptance filter, thus testing the acceptance filter logic). The loop back test ends with the host requesting this received message from the message RAM and then checking the contents of the output buffer.

Each FlexRay channel is tested separately. The FlexRay module cannot receive messages from the FlexRay bus while it is in the loop back mode.

The cycle counter value of frames used in loop back mode can be programmed by writing to the CCV bits of the MTCCV register (writable in ATM and loop back mode only).

NOTE: In case of an odd payload the last two bytes of the looped-back payload will be right aligned (shifted by 16 bits to the right) inside the last 32-bit data word.

The controller host interface command SEND_MTS results in the immediate transmission of an MTS symbol. Transmitted MTS symbols will not cause status interrupt flags MTSA,B to be set in the Status Interrupt Register. MTS symbols received while operating in loop back mode will set status interrupt flags MTSA,B in System Interrupt Register like in monitor mode. The reception of an MTS symbol can be emulated by driving the FlexRay receive pins RxD1,2 to low for the duration of the symbol in external loop back mode, or by driving the FlexRay pins TxD1,2 and TxEN1,2 to low using the TXA,B and TXENA,B of Test Register1 in internal or external loop back mode.

26.3.2.1.6 Test Register 2 (TEST2)

Test register 2 holds all bits required for RAM test of the embedded RAM blocks of the communication controller. Write access to this register is only possible when bit WRTEN in the test register 1 is set.

Figure 26-114 and Table 26-94 illustrate this register.

Figure 26-114. Test Register 2 (TEST2) [offset_CC = 14h]

31															16
Reserved															
R-0															

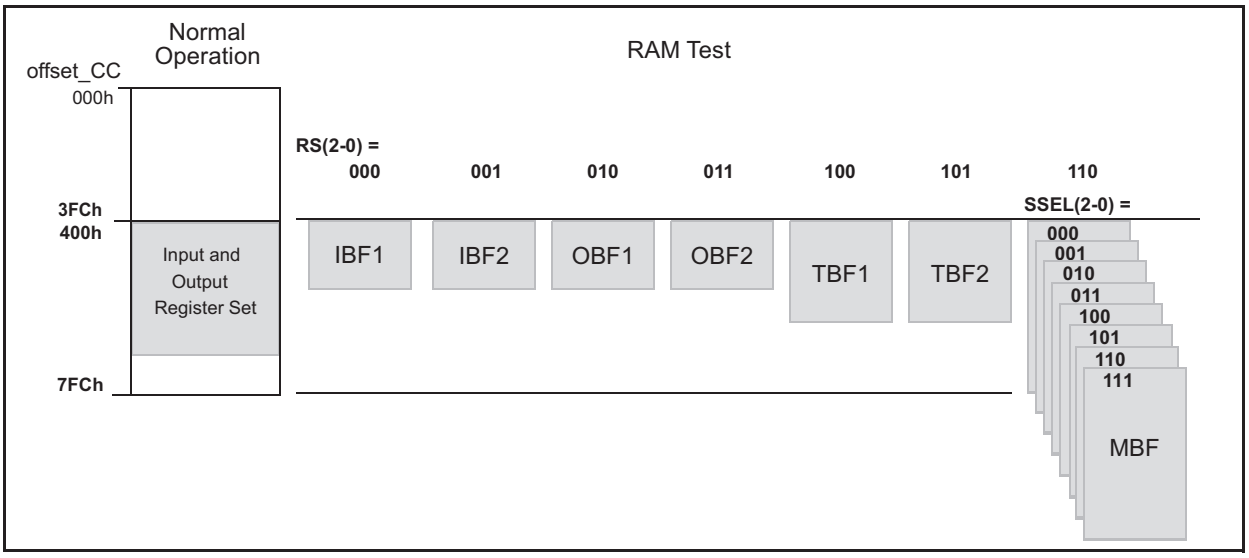
15	14	13	7	6	4	3	1	0
RDPB	WRPB	Reserved		SSEL		Rsvd	RS	
R-0	R/W-0	R-0		R/W-0		R-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-94. Test Register 2 (TEST2) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0. Writes have no effect.
15	RDPB	0-1	When ECC mode is enabled, this bit is always read as 0.
14	WRPB	0-1	When ECC mode is enabled, this bit has no effect.
13-7	Reserved	0	Reads return 0. Writes have no effect.
6-4	SSEL		Segment select. To enable access to the complete message RAM (8192 byte addresses) the message RAM is segmented.
		0	Access to RAM bytes 0000h to 03FFh is enabled.
		1h	Access to RAM bytes 0400h to 07FFh is enabled.
		2h	Access to RAM bytes 0800h to 0BFFh is enabled.
		3h	Access to RAM bytes 0C00h to 0FFFh is enabled.
		4h	Access to RAM bytes 1000h to 13FFh is enabled.
		5h	Access to RAM bytes 1400h to 17FFh is enabled.
		6h	Access to RAM bytes 1800h to 1BFFh is enabled.
		7h	Access to RAM bytes 1C00h to 1FFFh is enabled.
3	Reserved	0	Reads return 0. Writes have no effect.
2-0	RS		RAM select. In RAM test mode, the RAM blocks selected by RS are mapped to module address 400h to 7FFh (1024 byte addresses).
		0	Input buffer RAM 1
		1h	Input buffer RAM 2
		2h	Output buffer RAM 1
		3h	Output buffer RAM 2
		4h	Transient buffer RAM A
		5h	Transient buffer RAM B
		6h	Message RAM
		7h	Reserved

Copyright © 2018, Texas Instruments Incorporated



26.3.2.1.6.1 RAM Test Mode

In RAM test mode [TMC = 01], one of the seven RAM blocks can be selected for direct read and write access by programming the RS field to the corresponding value; see Figure 26-115.

For external RAM access in RAM test mode, the selected RAM block is mapped to the address range offset_CC 400h to 7FFh, which is the address space for the input and output buffer register sets in normal operation. Hence, the functionality of the input and output buffer register sets is not available in RAM test mode.

With the available address space (offset_CC 400h to 7FFh) in RAM test mode, 1024 bytes of RAM can be addressed for direct access. Since the length of the Message RAM exceeds the available address space, the Message RAM is segmented into segments of 1024 bytes. The segments can be selected by programming the bits SSEL(2-0) of test register 2.

Figure 26-115. Test Mode Access to Communication Controller RAM Blocks

26.3.2.1.7 Lock Register (LCK)

The lock register is write-only. Reading the register will return 00.

Figure 26-116 and Table 26-95 illustrate this register.

Figure 26-116. Lock Register (LCK) [offset_CC = 1Ch]

31								16
Reserved								
R-0								
15				8	7			0
TMK					CLK			
R/W-0					R/W-0			

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-95. Lock Register (LCK) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0. Writes have no effect.
15-8	TMK	0-1FFh	Test mode key. To write bit WRTEN in the test register to 1, the write operation has to be directly preceded by two consecutive write accesses to the test mode key (unlock sequence). If this write sequence is interrupted by other write accesses, bit WRTEN is not set to 1 and the sequence has to be repeated. First write (LCK.TMK): 75h = 0b0111 0101 Second write (LCK.TMK): 8Ah = 0b1000 1010 Third write: TEST1.WRTEN = 1
7-0	CLK	0-FFh	Configuration lock key. To leave CONFIG state by writing to CMD in the SUC configuration register 1 (commands READY; MONITOR_MODE; ATM; LOOP_BACK), the write operation has to be directly preceded by two consecutive write accesses to the configuration lock key (unlock sequence). If this write sequence is interrupted by other write accesses, the communication controller remains in CONFIG state and the sequence has to be repeated. First write (LCK.CLK): CEh = 0b1100 1110 Second write (LCK.CLK): 31h = 0b0011 0001 Third write (SUCC.CMD)

NOTE: In case that the Host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no "dummy accesses" (for example, the remaining register bytes / words) are inserted by the compiler.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.2 Interrupt Registers

26.3.2.2.1 Error Interrupt Register (EIR)

The flags are set when the communication controller detects one of the listed error conditions. They remain set until the host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. A reset will also clear the register.

Figure 26-117 and Table 26-96 illustrate this register.

Figure 26-117. Error Interrupt Register (EIR) [offset_CC = 20h]

31	27	26	25	24	23	19	18	17	16

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-96. Error Interrupt Register (EIR) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26	TABB		Transmission Across Boundary Channel B. The flag signals to the Host that a transmission across a slot boundary occurred for channel B.
		0	No transmission across slot boundary is detected on channel B.
		1	Transmission across slot boundary is detected on channel B.
25	LTVB		Latest transmit violation channel B. The flag signals a latest transmit violation on channel B to the host.
		0	No latest transmit violation is detected on channel B.
		1	Latest transmit violation is detected on channel B.
24	EDB		Error detected on channel B. This bit is set whenever one of the flags SEDB, CEDB, CIB, SBVB in the Aggregated channel status register is set.
		0	No error is detected on channel B.
		1	Error is detected on channel B.
23-19	Reserved	0	Reads return 0. Writes have no effect.
18	TABA		Transmission Across Boundary Channel A. The flag signals to the Host that a transmission across a slot boundary occurred for channel A.
		0	No transmission across slot boundary is detected on channel A.
		1	Transmission across slot boundary is detected on channel A.
17	LTVA		Latest transmit violation channel A. The flag signals a latest transmit violation on channel A to the host.
		0	No latest transmit violation is detected on channel A.
		1	Latest transmit violation is detected on channel A.
16	EDA		Error detected on channel A. This bit is set whenever one of the flags SEDA, CEDA, CIA, SBVA in the Aggregated channel status register is set.
		0	No error is detected on channel A.
		1	Error is detected on channel A.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	MHF		Message Handler Constraints Flag. The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags MHDF.SNUA, MHDF.SNUB, MHDF.FNFA, MHDF.FNFB, MHDF.TBFA, MHDF.TBFB, MHDF.WAHP changes from 0 to 1.
		0	No Message Handler failure is detected.
		1	Message Handler failure is detected.

Copyright © 2018, Texas Instruments Incorporated

Table 26-96. Error Interrupt Register (EIR) Field Descriptions (continued)

Bit	Field	Value	Description
10	IOBA		Illegal Output buffer Access. This flag is set by the communication controller when the Host requests the transfer of a message buffer from the Message RAM to the Output Buffer while OBCR.OBSYS is set to 1.
		0	No illegal Host access to Output Buffer occurred.
		1	Illegal Host access to Output Buffer occurred.
9	IIBA		Illegal Input Buffer Access. This flag is set by the communication controller when the Host wants to modify a message buffer via Input Buffer and one of the following conditions applies: • The communication controller is not in CONFIG or DEFAULT_CONFIG state and the Host writes to the Input Buffer Command Request register to modify the following: – the Header section of message buffer 0, 1 if configured for transmission in key slot – the Header section of static message buffers with buffer number < MRC.FDB while MRC.SEC = 01 – the Header section of any static or dynamic message buffer while MRC.SEC = 1x – Header and / or data section of any message buffer belonging to the receive FIFO • The Host writes to any register of the Input Buffer while IBCR.IBSYH is set to 1.
		0	No illegal Host access to Input Buffer occurred.
		1	Illegal Host access to Input Buffer occurred.
8	EFA		Empty FIFO Access. This flag is set by the communication controller when the Host requests the transfer of a message from the receive FIFO via Output Buffer while the receive FIFO is empty.
		0	No Host access to empty FIFO occurred.
		1	Host access to empty FIFO occurred.
7	RFO		Receive FIFO overrun. This flag is set by the communication controller when a receive FIFO overrun was detected. The flag is cleared by the next FIFO read access of the host. After this read access one position in the FIFO is empty again.
		0	No receive FIFO overrun is detected.
		1	A receive FIFO overrun is detected.
6	PERR		ECC error. The flag signals an ECC multi-bit error to the host. The flag is set by the ECC logic of the communication controller, when it detects an ECC multi-bit error while reading from one of the FlexRay RAM blocks. Note: ECC single-bit errors are indicated by a separate SBE bit in the Single-Bit Error Status Register (SBESTAT).
		0	No ECC multi-bit error is detected.
		1	ECC multi-bit error is detected.
5	CCL		CHI Command Locked. The flag signals that the write access to the CHI command vector SUCC1.CMD was not successful because it coincided with a POC state change triggered by protocol functions. In this case bit CNA is also set to 1.
		0	CHI command is accepted.
		1	CHI command is not accepted.
4	CCF		Clock correction failure. This flag is set at the end of the cycle whenever one of the following errors occurred: • Missing rate correction signal • Missing offset correction signal • Clock correction Failed counter stopped at 15 • Clock correction Limit Reached The clock correction status is monitored in the communication controller error vector and sync frame status register.
		0	No clock correction error.
		1	Clock correction failed.
3	SFO		Sync frame overflow. Set when either the number of sync frames received during the last communication cycle or the total number of different sync frame IDs received during the last double cycle exceeds the maximum number of sync frames as defined by SNM in the GTU configuration register 2.
		0	Number of received sync frames in the configured range.
		1	More sync frames received than configured by SNM.

Copyright © 2018, Texas Instruments Incorporated

Table 26-96. Error Interrupt Register (EIR) Field Descriptions (continued)

Bit	Field	Value	Description
2	SFBM		Sync frames below minimum. This flag signals that the number of sync frames received during the last communication cycle was below the limit required by the FlexRay protocol. The minimum number of sync frames per communication cycle is 2.
		0	Two or more sync frames are received during last communication cycle.
		1	Less than two sync frames are received during last communication cycle.
1	CNA		Command not accepted. The flag signals that the controller host interface command vector CMD in the SUC configuration register 1 was reset to 0000 due to an unaccepted controller host interface command.
		0	Controller host interface command is accepted.
		1	Controller host interface command is not accepted.
0	PEMC		POC error mode changed. This flag is set whenever the error mode signaled by ERRM in the communication controller error vector register has changed.
		0	Error mode has not changed.
		1	Error mode has changed.

26.3.2.2.2 Status Interrupt Register (SIR)

The flags are set by the communication controller when a corresponding event occurs. They remain set until the host clears them. If enabled, an interrupt is pending while one of the bits is set. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. A hardware reset will also clear the register.

Figure 26-118 and Table 26-97 illustrate this register.

Figure 26-118. Status Interrupt Register (SIR) [offset_CC = 24h]

31						26	25	24	23						18	17	16

Table 26-97. Status Interrupt Register (SIR) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reads return 0. Writes have no effect.
25	MTSB		MTS received on channel B. Media access test symbol received on channel B during the last symbol window. Updated by the communication controller for each channel at the end of the symbol window.
		0	No MTS symbol is received.
		1	MTS symbol is received.
24	WUPB		Wakeup pattern channel B. This flag is set by the communication controller when a wakeup pattern was received on channel B.
		0	No wakeup pattern is on channel B.
		1	Wakeup pattern is on channel B.
23-18	Reserved	0	Reads return 0. Writes have no effect.
17	MTSA		MTS received on channel A. Media access test symbol received on channel A during the last symbol window. Updated by the communication controller for each channel at the end of the symbol window.
		0	No MTS symbol is received.
		1	MTS symbol is received.

Copyright © 2018, Texas Instruments Incorporated

Table 26-97. Status Interrupt Register (SIR) Field Descriptions (continued)

Bit	Field	Value	Description
16	WUPA		Wakeup pattern channel A. This flag is set by the communication controller when a wakeup pattern was received on channel A.
		0	No wakeup pattern is on channel A.
		1	Wakeup pattern is on channel A.
15	SDS		Start of Dynamic Segment. This flag is set by the communication controller when the dynamic segment starts.
		0	Dynamic segment is not yet started.
		1	Dynamic segment is started.
14	MBSI		Message buffer status interrupt. This flag is set by the communication controller if bit MBI of a dedicated receive buffer is set to 1 and when the status of that message buffer has been updated due to reception of a: • valid frame with payload • valid frame with payload zero • null frame • corrupted frame or an empty slot
		0	No message buffer status has been updated.
		1	Message buffer status of at least one receive buffer has been updated.
13	SUCS		Startup completed successfully. This flag is set whenever a startup completed successfully and the communication controller entered NORMAL_ACTIVE state.
		0	No startup is completed successfully.
		1	Startup is completed successfully.
12	SWE		Stop watch event. If enabled by the respective control bits located in the Stop watch register, a detected edge on external stop watch pin or a software trigger event will generate a stop watch event.
		0	No stop watch event.
		1	Stop watch event occurred.
11	TOBC		Transfer output buffer completed. This flag is set whenever a transfer from the message RAM to the output buffer has completed and bit OBSYS in the output buffer command request register has been reset by the message handler.
		0	No transfer is completed since bit was reset.
		1	Transfer between message RAM and output buffer is completed.
10	TIBC		Transfer input buffer completed. This flag is set whenever a transfer from input buffer to the message RAM has completed and bit IBSYS in the input buffer command request register has been reset by the message handler.
		0	No transfer is completed since bit was reset.
		1	Transfer between input buffer and message RAM is completed.
9	TI1		Timer interrupt 1. This flag is set whenever the conditions programmed in the timer interrupt 1 configuration register are met. A timer interrupt 1 is also signaled on pin CC_tint1.
		0	No timer interrupt 1.
		1	Timer interrupt 1 occurred.
8	TI0		Timer interrupt 0. This flag is set whenever the conditions programmed in the timer interrupt 0 configuration register are met. A timer interrupt 0 is also signaled on pin CC_tint0.
		0	No timer interrupt 0.
		1	Timer interrupt 0 occurred.
7	NMVC		Network management vector changed. This interrupt flag signals a change in the Network management vector visible to the host.
		0	No change in the network management vector.
		1	Network management vector is changed.
6	RFCL		Receive FIFO critical level. This flag is set when the receive FIFO fill level FSR.RFFL is equal or greater than the critical level as configured by FCL.CL.
		0	Receive FIFO is below critical level.
		1	Receive FIFO critical level is reached.

Copyright © 2018, Texas Instruments Incorporated

Table 26-97. Status Interrupt Register (SIR) Field Descriptions (continued)

Bit	Field	Value	Description
5	RFNE		Receive FIFO not empty. This flag is set by the communication controller when a received valid frame was stored into the empty receive FIFO. The actual state of the receive FIFO is monitored in register FSR.
		0	Receive FIFO is empty.
		1	Receive FIFO is not empty.
4	RXI		Receive interrupt. This flag is set by the communication controller when the payload segment of a received valid frame was stored into the data section of a matching dedicated receive buffer and if bit MBI of that message buffer is set to 1.
		0	No data section has been updated.
		1	At least one data section has been updated.
3	TXI		Transmit interrupt. This flag is set by the communication controller after successful frame transmission if bit MBI in the respective message buffer is set to 1.
		0	No frame is transmitted.
		1	At least one frame was transmitted successfully.
2	CYCS		Cycle start interrupt. This flag is set by the communication controller when a communication cycle starts.
		0	No communication cycle is started.
		1	Communication cycle is started.
1	CAS		Collision avoidance symbol. This flag is set by the communication controller when a CAS was received.
		0	No CAS symbol is received.
		1	CAS symbol is received.
0	WST		This flag is set when WSV in the communication controller status vector register changes to a value other than UNDEFINED.
		0	Wakeup status is unchanged.
		1	Wakeup status is changed.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.2.3 Error Interrupt Line Select (EILS)

The settings in the error interrupt line select register assigns an interrupt generated by a specific error interrupt flag to one of the two module interrupt lines (CC_int0 or CC_int1).

Figure 26-119 and Table 26-98 illustrate this register.

Figure 26-119. Error Interrupt Line Select Register (EILS) [offset_CC = 28h]

26.3.2.2.5 Error Interrupt Enable Set / Reset (EIES/EIER)

The settings in the error interrupt enable register determine which status changes in the error interrupt register will result in an interrupt. The enable bits are set by writing to EIES (address 30h) and reset by writing to EIER (address 34h). Writing 1 sets or resets the specific enable bit, writing 0 has no effect.

Figure 26-121 and Table 26-100 illustrate this register.

Figure 26-121. Error Interrupt Enable Set/Reset Register (EIES/EIER) [offset_CC = 30h/34h]

26.3.2.2.6 Status Interrupt Enable Set / Reset Register (SIES/SIER)

The settings in the status interrupt enable register determine which status changes in the status interrupt register will result in an interrupt. The enable bits are set by writing to SIES (address 38h) and reset by writing to SIER (address 3Ch). Writing 1 sets or resets the specific enable bit, writing 0 has no effect.

Figure 26-122 and Table 26-101 illustrate this register.

Figure 26-122. Status Interrupt Enable Set/Reset Register (SIES/SIER) [offset_CC = 38h/3Ch]

26.3.2.2.8 Timer 0 Configuration Register (T0C)

This absolute timer specifies, in terms of cycle count and macrotick, the point in time when the timer 0 interrupt occurs. The timer 0 interrupt generates a non maskable interrupt signal on CC_tint0.

Timer 0 can be activated as long as the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state. Timer 0 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing bit T0RC to 0.

Figure 26-124 and Table 26-103 illustrate this register.

Figure 26-124. Timer 0 Configuration Register (T0C) [offset_CC = 44h]

31	30	29	16
Reserved		TOMO	
R-0		R/W-0	

15	14	8	7	2	1	0
Rsvd	TOCC		Reserved		TOMS	TORC
R-0	R/W-0		R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-103. Timer 0 Configuration Register (T0C) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reads return 0. Writes have no effect.
29-16	TOMO	0-3FFFh	Timer 0 macrotick offset. Configures the macrotick offset from the beginning of the cycle where the interrupt is to occur. The Timer 0 interrupt occurs at this offset for each cycle in the cycle set.
15	Reserved	0	Reads return 0. Writes have no effect.
14-8	TOCC	0-FFh	Timer 0 cycle code. The 7-bit timer 0 cycle code determines the cycle set used for generation of the timer 0 interrupt.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	TOMS		Time 0 mode select.
		0	Single-shot mode.
		1	Continuous mode.
0	TORC		Timer 0 run control.
		0	Timer 0 is halted.
		1	Timer 0 is running.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.2.9 Timer 1 Configuration Register (T1C)

This relative timer generates an interrupt on the non maskable interrupt signal CC_tint1 after the specified number of macroticks has expired.

Timer 1 can be activated as long as the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state. Timer 1 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing bit T1RC to 0.

Figure 26-125 and Table 26-104 illustrate this register.

Figure 26-125. Timer 1 Configuration Register (T1C) [offset_CC = 48h]

31	30	29	16
Reserved		TIMC	
R-0		R/W-2h	

15	2	1	0

R-0		R/W-0	

LEGEND: R = Read only; -*n* = value after reset

Table 26-104. Timer 1 Configuration Register (T1C) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reads return 0. Writes have no effect.
29-16	TIMC		Timer 1 macrotick count. When the configured macrotick count is reached the timer 1 interrupt is generated. In case the configured macrotick count is not within the valid range, timer 1 will not start. Valid values: • 2 to 16383 macroticks in continuous mode • 1 to 16383 macroticks in single-shot mode
		2h-3FFFh	Continuous mode.
		1h-3FFFh	Single-shot mode.
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	T1MS		Timer 1 mode select.
		0	Single-shot mode.
		1	Continuous mode.
0	T1RC		Timer 1 run control.
		0	Timer 1 is halted.
		1	Timer 1 is running.

26.3.2.2.10 Stop Watch Register 1 Register (STPW1)

The stop watch is activated by an interrupt event (CC_int0 or CC_int1), by writing bit SSWT to 1, or by an external event.

With the macrotick counter increment following next to the stop watch activation the actual cycle counter and macrotick value is stored in the stop watch register 1 (stop watch event) and the slot counter values for channel A and channel B are stored in stop watch register 2.

Figure 26-126 and Table 26-105 illustrate this register.

Figure 26-126. Stop Watch Register 1 (STPW1) [offset_CC = 4Ch]

31	30	29										16
Reserved		SMTV										
R-0		R-0										

15	14	13	8	7	6	5	4	3	2	1	0
Reserved		SCCV		Rsvd	EINT1	EINT0	EETP	SSWT	EDGE	SWMS	ESWT
R-0		R-0		R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-105. Stop Watch Register 1 (STPW1) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reads return 0. Writes have no effect.
29-16	SMTV	0-3E80h	Stopped macrotick value. State of the macrotick counter when the stop watch event occurred.
15-14	Reserved	0	Reads return 0. Writes have no effect.
13-8	SCCV	0-3Fh	Stopped cycle counter value. State of the cycle counter when the stop watch event occurred.
7	Reserved	0	Reads return 0. Writes have no effect.
6	EINT1		Enable interrupt 1 trigger. Enables stop watch trigger by CC_int1 event if ESWT = 1.
		0	Stop watch trigger by CC_int1 is disabled.
		1	CC_int1 event triggers stop watch.
5	EINT0		Enable interrupt 0 trigger. Enables stop watch trigger by CC_int0 event if ESWT = 1.
		0	Stop watch trigger by CC_int0 is disabled.
		1	CC_int0 event triggers stop watch.
4	EETP		Enable external trigger pin. Enables stop watch trigger event from external pin, if ESWT = 1.
		0	External trigger is disabled.
		1	Stop watch is activated by external trigger.
3	SSWT		Software stop watch trigger. When the host writes this bit to 1, the stop watch is activated. After the actual cycle counter and macrotick value are stored in the stop watch register, this bit is reset to 0. The bit is only writable while ESWT = 0.
		0	Software trigger is reset.
		1	Stop watch is activated by software trigger.
2	EDGE		Stop watch trigger edge select.
		0	Falling edge.
		1	Rising edge.
1	SWMS		Stop watch mode select.
		0	Single-shot mode.
		1	Continuous mode.
0	ESWT		External stop watch trigger. If enabled, an external event activates the stop watch. In single-shot mode, this bit is reset to 0 after the stop watch event occurred.
		0	External stop watch trigger is disabled.
		1	External stop watch trigger is enabled.

Copyright © 2018, Texas Instruments Incorporated

NOTE: Bits ESWT and SSWT cannot be set to 1 simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

The availability of an external stop watch pin is device dependant. Refer to the device data sheet for details.

26.3.2.2.11 Stop Watch Register 2 Register (STPW2)

Figure 26-127 and Table 26-106 illustrate this register.

Figure 26-127. Stop Watch Register 2 (STPW2) [offset_CC = 50h]

26.3.2.3 Control Registers

This section describes the registers provided by the communication controller to allow the host to control the operation of the communication controller. The FlexRay protocol specification requires the host to write application configuration data in CONFIG state only.

NOTE: Be aware that the configuration registers are not locked for writing in DEFAULT_CONFIG state.

The configuration data is reset when DEFAULT_CONFIG state is entered from hardware reset. To change POC state from DEFAULT_CONFIG to CONFIG state the host has to apply the controller host interface command CONFIG. If the host wants the communication controller to leave CONFIG state, the host has to proceed as described in Lock Register (LCK).

NOTE: All bits marked with an asterisk (*) can be updated in DEFAULT_CONFIG or CONFIG state only.

26.3.2.3.1 SUC Configuration Register 1 (SUCC1)

The communication controller accepts modifications of the register in DEFAULT_CONFIG or CONFIG state only.

Figure 26-128 and Table 26-107 illustrate this register.

Figure 26-128. SUC Configuration Register 1 (SUCC1) [offset_CC = 80h]

31	28	27	26	25	24	23	22	21	20	16
Reserved		CCHB*	CCHA*	MTSB*	MTSA*	HCSE*	TSM*	WUCS*	PTA*	
R-0		R/W-1	R/W-1	R/W-0	R/W-0	R/W-0	R/W-1	R/W-0	R/W-0	

15	11	10	9	8	7	6	4	3	0
CSA*		Rsvd	TXSY*	TXST*	PBSY	Reserved		CMD*	
R/W-2h		R-0	R/W-0	R/W-0	R-1	R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; *These bits can be updated in DEFAULT_CONFIG or CONFIG state only

Table 26-107. SUC Configuration Register 1 (SUCC1) Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Reads return 0. Writes have no effect.
27	CCHB		Connected to channel B. Configures whether the node is connected to channel B.
		0	Node is not connected to channel B.
		1	Node is connected to channel B (default by hardware reset).
26	CCHA		Connected to channel A. Configures whether the node is connected to channel A.
		0	Node is not connected to channel A.
		1	Node is connected to channel A (default by hardware reset).
25	MTSB		Select channel B for MTS Transmission. The bit selects channel B for MTS symbol transmission if requested by writing CMD = 8h. The flag is reset by default and may be modified only in DEFAULT_CONFIG or CONFIG state.
		0	Channel B is not selected for MTS transmission.
		1	Channel B is selected for MTS transmission.
			Note: MTSB may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to SUC Configuration Register 1 (SUCC1) is directly preceded by the unlock sequence for the Configuration Lock Key as described in the Lock Register (LCK). This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing CMD = 8h.

Copyright © 2018, Texas Instruments Incorporated

Table 26-107. SUC Configuration Register 1 (SUCC1) Field Descriptions (continued)

Bit	Field	Value	Description
24	MTSA		Select channel A for MTS Transmission. The bit selects channel A for MTS symbol transmission if requested by writing CMD = 8h. The flag is reset by default and may be modified only in DEFAULT_CONFIG or CONFIG state.
		0	Channel A is not selected for MTS transmission.
		1	Channel A is selected for MTS transmission.
			Note: MTSA may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to SUC Configuration Register 1 (SUCC1) is directly preceded by the unlock sequence for the Configuration Lock Key as described in the Lock Register (LCK). This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing CMD = 8h.
23	HCSE		Halt due to clock sync error. Controls reaction of the communication controller to a clock synchronization error. The bit can be modified in DEFAULT_CONFIG or CONFIG state only.
		0	Communication controller will enter or remain in NORMAL_PASSIVE.
		1	Communication controller will enter HALT state.
22	TSM		Transmission slot mode. Selects the initial transmission slot mode. In SINGLE slot mode the communication controller may only transmit in the pre-configured key slot. This slot is defined by the key slot ID, which is configured in the header section of message buffer 0. In all slot mode the communication controller may transmit in all slots. The bit can be written in DEFAULT_CONFIG or CONFIG state only. The communication controller changes to all slot mode when the host successfully applied the ALL_SLOTS command by writing CMD = 5h in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. The actual slot mode is monitored by SLM in register CCSV.
		0	All slot mode.
		1	Single slot mode (default by hardware reset).
21	WUCS		Wakeup channel select. With this bit the host selects the channel on which the communication controller sends the Wakeup pattern. The communication controller ignores any attempt to change the status of this bit when not in DEFAULT_CONFIG or CONFIG state.
		0	Send wakeup pattern on channel A.
		1	Send wakeup pattern on channel B.
20-16	PTA	0-1Fh even/odd cycle pairs	Passive to active. Defines the number of consecutive even/odd cycle pairs that must have valid clock correction terms before the communication controller is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state. If set to 0, the communication controller is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state. It can be modified in DEFAULT_CONFIG or CONFIG state only.
15-11	CSA	2h-1Fh	Cold start attempts. Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node. It can be modified in DEFAULT_CONFIG or CONFIG state only. Must be identical in all nodes of a cluster.
10	Reserved	0	Reads return 0. Writes have no effect.
9	TXSY		Transmit sync frame in key slot. Defines whether the key slot is used to transmit a sync frame. The bit can be modified inDEFAULT_CONFIG or CONFIG state only.
			Note: The protocol requires that both bits TXST and TXSY are set for coldstart nodes.
		0	No sync frame transmission in key slot, node is neither sync nor coldstart node.
		1	Key slot used to transmit sync frame, node is sync node.
8	TXST		Transmit startup frame in key slot. Defines whether the key slot is used to transmit a startup frame. The bit can be modified in DEFAULT_CONFIG or CONFIG state only.
			Note: The protocol requires that both bits TXST and TXSY are set for coldstart nodes.
		0	No startup frame transmitted in key slot, node is non-coldstarter.
		1	Key slot used to transmit startup frame, node is leading or following coldstarter.
7	PBSY		POC busy. Signals that the POC is busy and cannot accept a command from the host. CMD is locked against write accesses.
		0	POC is not busy, CMD is writable.
		1	POC is busy, CMD is locked.
6-4	Reserved	0	Reads return 0. Writes have no effect.

Table 26-107. SUC Configuration Register 1 (SUCC1) Field Descriptions (continued)

Bit	Field	Value	Description
3-0	CMD		The controller host interface command vector. The host may write any controller host interface command at any time, but certain commands are enabled only in certain POC states. If a command is not enabled, it will not be executed, the controller host interface command vector CMD will be reset to 0000 = command_not_accepted, and flag CNA in the error interrupt register will be set to 1. In case the previous controller host interface (CHI) command has not yet completed, EIR.CCL is set to 1 together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, a POC state change command applied while the communication controller is already in the requested POC state neither causes a state change nor will EIR.CNA be set.
		0	command_not_accepted
		1h	CONFIG
		2h	READY
		3h	WAKEUP
		4h	RUN
		5h	ALL_SLOTS
		6h	HALT
		7h	FREEZE
		8h	SEND_MTS
		9h	ALLOW_COLDSTART
		Ah	RESET_STATUS_INDICATORS
		Bh	MONITOR_MODE
		Ch	CLEAR_RAMS
		Dh-Eh	Reserved
		Fh	LOOPBACK MODE

Controller Host Interface Command Vector:

The following gives more information about the controller host interface commands.

- Reading CMD shows whether the last controller host interface command was accepted.
- The actual POC state is monitored by POCS in the communication controller status vector
- In most cases the Host must check SUCC1.PBSY before writing a new CHI command.

command_not_accepted

CMD is reset to 0000 due to one of the following conditions:

- Illegal command applied by the host
- Host applied command to leave CONFIG state without preceding configuration lock key
- Host applied new command while execution of the previous host command has not completed
- Host writes command_not_accepted

When CMD is reset to 0000 due to an unaccepted command, bit CNA in the error interrupt register is set, and, if enabled, an interrupt is generated. Commands which are not accepted are not executed.

CONFIG

Go to POC state CONFIG when called in POC states DEFAULT_CONFIG, READY, or in MONITOR_MODE. When called in HALT state the communication controller transits to POC state DEFAULT_CONFIG. When called in any other state, CMD will be reset to 0000 = command_not_accepted.

READY

Go to POC state READY when called in POC states CONFIG, NORMAL_ACTIVE, NORMAL_PASSIVE, STARTUP, or WAKEUP. When called in any other state, CMD will be reset to 0000 = command_not_accepted.

Copyright © 2018, Texas Instruments Incorporated

WAKEUP

Go to POC state WAKEUP when called in POC state READY. When called in any other state, CMD will be reset to 0000 = command_not_accepted.

RUN

Go to POC state STARTUP when called in POC state READY. When called in any other state, CMD will be reset to 0000 = command_not_accepted.

ALL_SLOTS

Leave single slot mode after successful startup / integration at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, CMD will be reset to 0000 = command_not_accepted.

HALT

Set the Halt request HRQ bit in the communication controller status vector register and go to POC state HALT at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, CMD will be reset to 0000 = command_not_accepted.

FREEZE

Go to POC state HALT immediately and set the Freeze status Indicator FSI bit in the communication controller status vector register. Can be called from any state.

SEND_MTS

Send single MTS symbol during the symbol window of the following cycle on the channel configured by MTSA, MTSB, when called in POC state NORMAL_ACTIVE. When called in any other state, CMD will be reset to 0000 = command_not_accepted.

ALLOW_COLDSTART

The command resets bit CSI in the CCSV register to enable coldstarting of the node when called in any POC state except DEFAULT_CONFIG, CONFIG or HALT. When called in these states, CMD will be reset to 0000 = command_not_accepted.

RESET_STATUS_INDICATORS

Reset status flags FSI, HRQ, CSNI, and CSAI in the communication controller status vector register.

CLEAR_RAMS

Sets bit CRAM in the message handler status register when called in DEFAULT_CONFIG or CONFIG state. When called in any other state, CMD will be reset to 0000 = command_not_accepted. Bit CRAM is also set when the communication controller leaves hardware reset. By setting bit CRAM, all internal RAM blocks are initialized to 0 and the ECC bits are initialized accordingly, depending what mode is enabled. During the initialization of the RAMs, PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS.

The initialization of the Communication Controller internal RAM blocks takes 2048 VBUS clock cycles. There should be no host access to IBF or OBF during initialization of the internal RAM blocks after hardware reset or after assertion of controller host interface command CLEAR_RAMS. Before asserting controller host interface command CLEAR_RAMS the host should be aware that no transfer between message RAM and IBF / OBF or the transient buffer RAMs is ongoing. This command also resets the message buffer status registers (MHDS, TXRQ1/2/3/4, NDAT1/2/3/4, MBSC1/2/3/4).

NOTE: All accepted commands with exception of CLEAR_RAMS and SEND_MTS will cause a change of the POC state in the VBUS clock domain after at most 8 cycles of the slower of the two clocks VBUS clock and 80MHz sample clock coming from the PLL. It is assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time frame. Reading register Communication Controller Status Vector (CCSV) will show data that is additionally delayed by synchronization from sample clock to VBUS clock domain and by the CPU interface. The maximum additional delay is 12 cycles of the slower of the two clocks VBUS clock and sample clock.

Copyright © 2018, Texas Instruments Incorporated

MONITOR_MODE

Enter MONITOR_MODE when called in POC state CONFIG. In this mode the communication controller is able to receive FlexRay frames and CAS / MTS symbols. It is also able to detect coding errors. The temporal integrity of received frames is not checked. This mode can be used for debugging purposes, for example, in case that the startup of a FlexRay network fails. When called in any other state, CMD will be reset to 0000 = command_not_accepted.

26.3.2.3.2 SUC Configuration Register 2 (SUCC2)

The communication controller accepts modifications of the register in DEFAULT_CONFIG or CONFIG state only.

Figure 26-129 and Table 26-108 illustrate this register.

Figure 26-129. SUC Configuration Register 2 (SUCC2) [offset_CC = 84h]

Table 26-108. SUC Configuration Register 2 (SUCC2) Field Descriptions

Bit	Field	Value	Description
31-28	Reserved.	0	Reads return 0. Writes have no effect.
27-24	LTN	2-Fh	Listen timeout noise. Configures the upper limit for the startup and wakeup listen timeout in the presence of noise. Must be identical in all nodes of a cluster. The wakeup / startup noise timeout is calculated as follows: LT × (LTN + 1).
23-21	Reserved.	0	Reads return 0. Writes have no effect.
20-0	LT	504h-139706h µT	Listen timeout. Configures the upper limit of the startup and wakeup listen timeout.

Bit	Field	Value	Description
31-8	Reserved.	0	Reads return 0. Writes have no effect.
7-4	WCF	1-Fh	Maximum without clock correction fatal. These bits define the number of consecutive even/odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE or NORMAL_PASSIVE state. These must be identical in all nodes of a cluster. **Note: The transition to HALT state is prevented if SUCC1.HCSE is not set.**
3-0	WCP	1-Fh	Maximum without clock correction passive. These bits define the number of consecutive even/odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE to NORMAL_PASSIVE to HALT state. These must be identical in all nodes of a cluster.

26.3.2.3.4 NEM Configuration Register (NEMC)

The communication controller accepts modifications of the register in DEFAULT_CONFIG or CONFIG state only.

Table 26-111. PRT Configuration Register 1 (PRTC1) Field Descriptions

Bit	Field	Value	Description
31-26	RWP	2h-3Fh	Repetition of transmission wakeup pattern. These bits configure the number of repetitions (sequences) of the transmission wakeup symbol.
25	Reserved	0	Reads return 0. Writes have no effect.
24-16	RXW	4Ch-12Dh	Wakeup symbol receive window length. Configures the number of bit times used by the node to test the duration of the received wakeup pattern. Must be identical in all nodes of a cluster.
15-14	BRP		Baud rate prescaler. These bits configure the baud rate on the FlexRay bus. The baud rates listed below are valid with a sample clock of 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate.
		0	10 Mbit/s (Sample Clock Period = 12.5ns; 1 µT = 25ns; Samples per µT = 2)
		1h	5 Mbit/s (Sample Clock Period = 25ns; 1 µT = 25ns; Samples per µT = 1)
		2h-3h	2.5 Mbit/s (Sample Clock Period = 50ns; 1 µT = 50ns; Samples per µT = 1)
13-12	SPP		Strobe Point Position. Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by SPP. **Note: The current revision 2.1 of the FlexRay protocol requires that SPP = 00. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.**
		0, 3h	Sample 5 (default)
		1h	Sample 4
		2h	Sample 6
11	Reserved	0	Reads return 0. Writes have no effect.
10-4	CASM	43h-63h bit times	Collision avoidance symbol max (in bit times). These bits configure the upper limit of the acceptance window for a collision avoidance symbol (CAS). CASM6 is always 1.
3-0	TSST	3h-Fh bit times	Transmission start sequence transmitter (in bit times). These bits configure the duration of the transmission start sequence (TSS) in terms of bit times (1 bit time = 4 µT = 100ns @ 10Mbps). Must be identical in all nodes of a cluster.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.3.6 PRT Configuration Register 2 (PRTC2)

The communication controller accepts modifications of the register in DEFAULT_CONFIG or CONFIG state only.

Figure 26-133 and Table 26-112 illustrate this register.

Table 26-113. MHD Configuration Register (MHDC) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reads return 0. Writes have no effect.
28-16	SLT	0-1F2Dh minislots	Start of latest transmit (in minislots). These bits configure the maximum minislot value allowed before inhibiting new frame transmissions in the Dynamic Segment of the cycle. There is no transmission in dynamic segment if SLT is cleared to 0.
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	SFDL	0-7Fh	Static frame data length. These bits configure the cluster-wide payload length for all frames sent in the static segment in double bytes. The payload length must be identical in all nodes of a cluster.

Bit	Field	Value	Description
31	Reserved	0	Reads return 0. Writes have no effect.
30-24	MIOB	2h-48h MT	Macrotick initial offset channel B (in macroticks). These bits configure the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration. Must be identical in all nodes of a cluster.
23	Reserved	0	Reads return 0. Writes have no effect.
22-16	MIOA	2h-48h MT	Macrotick initial offset channel A (in macroticks). These bits configure the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration. Must be identical in all nodes of a cluster.
15-8	UIOB	0-F0h µT	Microtick initial offset channel B (in microticks). These bits configure the number of microticks between the actual time reference point on channel B and the subsequent macrotick boundary of the secondary time reference point. The parameter has to be set for each channel independently.
7-0	UIOA	0-F0h µT	Microtick initial offset channel A (in microticks). These bits configure the number of microticks between the actual time reference point on channel A and the subsequent macrotick boundary of the secondary time reference point. The parameter has to be set for each channel independently.

Bit	Field	Value	Description
31-30	Reserved	0	Reads return 0. Writes have no effect.
29-16	OCS	8h-3E7Eh MT	Offset correction start (in macroticks). These bits determine the start of the offset correction within the NIT phase, calculated from start of cycle. Must be identical in all nodes of a cluster.
15-14	Reserved	0	Reads return 0. Writes have no effect.
13-0	NIT	7h-3E7Dh MT	Network idle time start (in macroticks). These bits configure the starting point of the network idle time (NIT) at the end of the communication cycle expressed in terms of macroticks from the beginning of the cycle. The number must be identical in all nodes of a cluster.

26.3.2.3.12 GTU Configuration Register 5 (GTUC5)

The communication controller accepts modifications of the register in DEFAULT_CONFIG or CONFIG state only. Figure 26-139 and Table 26-118 illustrate this register.

Bit	Field	Value	Description
31-24	DEC	Eh-8Fh µT	Decoding correction (in microticks). These bits configure the decoding correction value used to determine the primary time reference point.
23-21	Reserved.	0	Reads return 0. Writes have no effect.
20-16	CDD	0-14h µT	Cluster drift damping (in microticks). These bits configure the cluster drift damping value used in clock synchronization to minimize accumulation of rounding errors.
15-8	DCB	0-C8h µT	Delay compensation channel B (in microticks). These bits are used to compensate for reception delays on the indicated channel. This compensates propagation delays for microticks in the range of 0.0125 to 0.05s. In practice, the minimum propagation delay of all sync nodes should be applied.
7-0	DCA	0-C8h µT	Delay compensation channel A (in microticks). These bits are used to compensate for reception delays on the indicated channel. This compensates propagation delays for microticks in the range of 0.0125 to 0.05s. In practice, the minimum propagation delay of all sync nodes should be applied.

Bit	Field	Value	Description
31-29	Reserved	0	Reads return 0. Writes have no effect.
28-16	NMS	0-1F32h	Number of minislots. These bits configure the number of minislots in the dynamic segment of a cycle. The number of minislots must be identical in all nodes of a cluster.
15-6	Reserved	0	Reads return 0. Writes have no effect.
5-0	MSL	2h-3Fh MT	Minislot length (in macroticks). These bits configure the duration of a minislot. The minislot length must be identical in all nodes of a cluster.

26.3.2.3.16 GTU Configuration Register 9 (GTUC9)

The communication controller accepts modifications of the register in DEFAULT_CONFIG or CONFIG state only.

Figure 26-143 and Table 26-122 illustrate this register.

Figure 26-143. GTU Configuration Register 9 (GTUC9) [offset_CC = C0h]

31 18	17 16

Table 26-122. GTU Configuration Register 9 (GTUC9) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads return 0. Writes have no effect.
17-16	DSI	0-2h	Dynamic slot idle phase (in minislots). The duration of the dynamic slot idle phase has to be greater or equal than the idle detection time. Must be identical in all nodes of a cluster.
15-13	Reserved	0	Reads return 0. Writes have no effect.
12-8	MAPO	1h-1Fh MT	Minislot action point offset (in macroticks). These bits configure the minislot action point offset within the minislots of the dynamic segment. The minislot action point offset must be identical in all nodes of a cluster.
7-6	Reserved	0	Reads return 0. Writes have no effect.
5-0	APO	1h-3Fh MT	Action point offset (in macroticks). These bits configure the action point offset within static slots and symbol window. The action point offset must be identical in all nodes of a cluster.

Table 26-123. GTU Configuration Register 10 (GTUC10) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26-16	MRC	2h-783h µT	Maximum rate correction (in microticks). Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The communication controller checks the internal rate correction value against the maximum rate correction value (absolute value).
15-14	Reserved	0	Reads return 0. Writes have no effect.
13-0	MOC	5h-3BA2h µT	Maximum offset correction (in microticks). Holds the maximum permitted offset correction value to be applied by the internal clock synchronization algorithm (absolute value). The communication controller checks the internal offset correction value against the maximum offset correction value.

Table 26-124. GTU Configuration Register 11 (GTUC11) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26-24	ERC	0-7h µT	External rate correction (in microticks). Holds the external clock rate correction value to be applied by the internal clock synchronization algorithm. The value is subtracted/added from/to the calculated rate correction value. The value is applied during NIT. May be modified in DEFAULT_CONFIG or CONFIG state only.
23-19	Reserved	0	Reads return 0. Writes have no effect.
18-16	EOC	0-7h µT	External offset correction (in microticks). Holds the external clock offset correction value to be applied by the internal clock synchronization algorithm. The value is subtracted/added from/to the calculated offset correction value. The value is applied during NIT. May be modified in DEFAULT_CONFIG or CONFIG state only.
15-10	Reserved	0	Reads return 0. Writes have no effect.
9-8	ERCC		External rate correction control. By writing to ERCC, the external rate correction is enabled as specified below. Should be modified only outside NIT.
		0, 1h	No external rate correction.
		2h	External rate correction value is subtracted from calculated rate correction value.
		3h	External rate correction value is added to calculated rate correction value.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1-0	EOCC		External offset correction control. By writing to EOCC, the external offset correction is enabled as specified below. Should be modified only outside NIT.
		0-1h	No external offset correction.
		2h	External offset correction value is subtracted from calculated offset correction value.
		3h	External offset correction value is added to calculated offset correction value.

26.3.2.4 Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the communication controller between two accesses (non-atomic read accesses). All internal counters and the communication controller status flags are reset when the communication controller transits from CONFIG to READY state.

26.3.2.4.1 Communication Controller Status Vector (CCSV)

Figure 26-146 and Table 26-125 illustrate this register.

Figure 26-146. Communication Controller Status Vector Register (CCSV) [offset_CC = 100h]

31	30	29	24	23	19	18	16

LEGEND: R = Read only; -*n* = value after reset

Table 26-125. Communication Controller Status Vector Register (CCSV) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reads return 0. Writes have no effect.
29-24	PSL		POC Status Log. Status of POCS immediately before entering HALT state. Set when entering HALT state. Set to HALT when FREEZE command is applied during HALT state and FSI is not already set, that is, the HALT state was not reached by FREEZE command. Reset to 0 when leaving HALT state.
23-19	RCA	0-1Fh	Remaining coldstart attempts. Indicates the number of remaining coldstart attempts. The maximum number of coldstart attempts is configured by CSA(4-0) in the SUC configuration register 1.
18-16	WSV		Wakeup status. Indicates the status of the current wakeup attempt. Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to EFAULT_CONFIG state.
		0	UNDEFINED. No wakeup attempt since CONFIG state was left.
		1h	RECEIVED_HEADER. Set when the communication controller finishes wakeup due to the reception of a frame header without coding violation on either channel in WAKEUP_LISTEN or WAKEUP_DETECT state.
		2h	RECEIVED_WUP. Set when the communication controller finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in WAKEUP_LISTEN or WAKEUP_DETECT state.
		3h	COLLISION_HEADER. Set when the communication controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid header on either channel.
		4h	COLLISION_WUP. Set when the communication controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel.
		5h	COLLISION_UNKNOWN. Set when the communication controller stops wakeup by leaving WAKEUP_DETECT state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid frame header.
		6h	TRANSMITTED. Set when the communication controller has successfully completed the transmission of the wakeup pattern.
		7h	Reserved
15	Reserved	0	Reads return 0. Writes have no effect.
14	CSI		Cold start inhibit. Indicates that the node is disabled from cold starting. The flag is set whenever the POC enters READY state. The flag has to be reset under control of the host by the controller host interface command ALLOW_COLDSTART (CMD = 1001).
		0	Cold starting of node is enabled.
		1	Cold starting of node is disabled.
13	CSAI	0-1	Coldstart abort indicator. Coldstart aborted. Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

Copyright © 2018, Texas Instruments Incorporated

Table 26-125. Communication Controller Status Vector Register (CCSV) Field Descriptions (continued)

Bit	Field	Value	Description
12	CSNI	0-1	Coldstart noise indicator. Indicates that the cold start procedure occurred under noisy conditions. Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.
11-10	Reserved	0	Reads return 0. Writes have no effect.
9-8	SLM		Slot mode. Indicates the actual slot mode of the POC in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE. Default is SINGLE. Changes to ALL, depending on SUCC1.TSM. In NORMAL_ACTIVE or NORMAL_PASSIVE state the CHI command ALL_SLOTS will change the slot mode from SINGLE over ALL_PENDING to ALL. Set to SINGLE in all other states.
		0	SINGLE
		1h	Reserved
		2h	ALL_PENDING
		3h	ALL
7	HRQ	0-1	Halt request. Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle. Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or when entering READY state.
6	FSI	0-1	Freeze status indicator. Indicates that the POC has entered the HALT state due to CHI command FREEZE or due to an error condition requiring an immediate POC halt. Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state.
5-0	POCS		Protocol operation control status.
			Indicates the actual state of operation of the Communication Controller Protocol Operation Control:
		0	DEFAULT_CONFIG state
		1h	READY state
		2h	NORMAL_ACTIVE state
		3h	NORMAL_PASSIVE state
		4h	HALT state
		5h	MONITOR_MODE state
		6h-Ch	Reserved
		Dh	LOOPBACK MODE state
		Eh	Reserved
		Fh	CONFIG state
			Indicates the actual state of operation of the POC in the wakeup path:
		10h	WAKEUP_STANDBY state
		11h	WAKEUP_LISTEN state
		12h	WAKEUP_SEND state
		13h	WAKEUP_DETECT state
		14h-1Fh	Reserved
			Indicates the actual state of operation of the POC in the startup path:
		20h	STARTUP_PREPARE state
		21h	COLDSTART_LISTEN state
		22h	COLDSTART_COLLISION_RESOLUTION state
		23h	COLDSTART_CONSISTENCY_CHECK state
		24h	COLDSTART_GAP state
		25h	COLDSTART_JOIN state
		26h	INTEGRATION_COLDSTART_CHECK state
		27h	INTEGRATION_LISTEN state
		28h	INTEGRATION_CONSISTENCY_CHECK state
		29h	INITIALIZE_SCHEDULE state
		2Ah	ABORT_STARTUP state
		2Bh-3Fh	Reserved

Copyright © 2018, Texas Instruments Incorporated

NOTE: CHI command RESET_STATUS_INDICATORS (SUCC1.CMD = Ah) resets flags FSI, HRQ, CSNI, CSAI, the slot mode SLM, and the wakeup status WSV.

26.3.2.4.2 Communication Controller Error Vector (CCEV)

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

Figure 26-147 and Table 26-126 illustrate this register.

Figure 26-147. Communication Controller Error Vector Register (CCEV) [offset_CC = 104h]

Table 26-126. Communication Controller Error Vector Register (CCEV) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reads return 0. Writes have no effect.
12-8	PTAC	0-1Fh	Passive to active count. Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from NORMAL_PASSIVE state to NORMAL_ACTIVE state. The transition takes place when PTAC equals PTA - 1 as defined in the SUC configuration register 1.
7-6	ERRM		Error mode. Indicates the actual error mode of the POC.
		0	ACTIVE
		1h	PASSIVE
		2h	COMM_HALT
		3h	Reserved
5-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	CCFC	0-Fh	Clock correction failed counter. The clock correction failed counter is incremented by 1 at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active. The clock correction failed counter is reset to 0 at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active. The clock correction failed counter stops at 15.

R-0		R-0		R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 26-131. Sync Frame Status Register (SFS) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	Reads return 0. Writes have no effect.
19	RCLR		Rate correction limit reached. The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit as defined by GTUC10.MRC. The flag is updated by the communication controller at start of offset correction phase.
		0	Rate correction is below limit.
		1	Rate correction limit is reached.
18	MRCS		Missing rate correction signal. The missing rate correction signal signals to the host that no rate correction can be performed because no pairs of even/odd sync frames were received. The flag is updated by the communication controller at start of offset correction phase.
		0	Rate correction signal is valid.
		1	Missing rate correction signal.
17	OCLR		Offset correction limit reached. The offset correction limit reached flag signals to the host that the offset correction value has reached its limit as defined by GTUC10.MOC. The flag is updated by the communication controller at start of offset correction phase.
		0	Offset correction is below limit.
		1	Offset correction limit is reached.
16	MOCS		Missing offset correction signal. The missing offset correction signal signals to the host that no rate correction can be performed because no pairs of even / odd sync frames were received. The flag is updated by the communication controller at start of offset correction phase.
		0	Offset correction signal is valid.
		1	Missing offset correction signal.
15-12	VSBO	0-Fh	Valid sync frames channel B, odd communication cycle. Holds the number of valid sync frames received on channel B in the odd communication cycle. If transmission of sync frames is enabled by SUCC1.TXSY, the value is incremented by 1. The value is updated during the NIT of each odd communication cycle.
11-8	VSBE	0-Fh	Valid synch frames channel B, even communication cycle. Holds the number of valid sync frames received and transmitted on channel B in the even communication cycle. If transmission of sync frames is enabled by SUCC1.TXSY, the value is incremented by 1. The value is updated during the NIT of each even communication cycle.
7-4	VSAO	0-Fh	Valid synch frames channel A, odd communication cycle. Holds the number of valid sync frames received and transmitted on channel A in the odd communication cycle. If transmission of sync frames is enabled by SUCC1.TXSY, the value is incremented by 1. The value is updated during the NIT of each odd communication cycle.
3-0	VSAE	0-Fh	Valid synch frames channel A, even communication cycle. Holds the number of valid sync frames received and transmitted on channel A in the even communication cycle. If transmission of sync frames is enabled by SUCC1.TXSY, the value is incremented by 1. The value is updated during the NIT of each even communication cycle.

NOTE: The bit fields **VSBO**, **VSBE, VSAO, VSAE** are only valid if the respective channel is assigned to the communication controller by SUCC1.CCHA or SUCC1.CCHB.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.4.8 Symbol Window and NIT Status (SWNIT)

Symbol window related status information. Updated by the communication controller at the end of the symbol window for each channel. During startup the status data is not updated. This register is reset when the Communication Controller leaves CONFIG state or enters STARTUP state.

Figure 26-153 and Table 26-132 illustrate this register.

Figure 26-153. Symbol Window and NIT Status Register (SWNIT) [offset_CC = 124h]

Bit	Field	Value	Description
31-12	Reserved	0	Reads return 0. Writes have no effect.
11	SBNB		Slot boundary violation during NIT channel B.
		0	No slot boundary violation is detected.
		1	Slot boundary violation during NIT is detected on channel B.
10	SENB		Syntax error during NIT channel B.
		0	No syntax error is detected.
		1	Syntax error during NIT is detected on channel B.
9	SBNA		Slot boundary violation during NIT channel A.
		0	No slot boundary violation is detected.
		1	Slot boundary violation during NIT is detected on channel A.
8	SENA		Syntax error during NIT channel A.
		0	No syntax error is detected.
		1	Syntax error during NIT is detected on channel A.
7	MTSB		MTS Received on Channel B. Media Access Test symbol received on channel B during the last symbol window. Updated by the communication controller for each channel at the end of the symbol window. When this bit is set to 1, also interrupt flag SIR.MTSB is set to 1.
		0	No MTS symbol is received on channel B.
		1	MTS symbol is received on channel B.
6	MTSA		MTS Received on Channel A. Media Access Test symbol received on channel A during the last symbol window. Updated by the communication controller for each channel at the end of the symbol window. When this bit is set to 1, also interrupt flag SIR.MTSB is set to 1.
		0	No MTS symbol is received on channel A.
		1	MTS symbol is received on channel A.
5	TCSB		Transmission conflict in symbol window channel B.
		0	No transmission conflict is detected.
		1	Transmission conflict in symbol window is detected on channel B.
4	SBSB		Slot boundary violation in symbol window channel B.
		0	No slot boundary violation is detected.
		1	Slot boundary violation during symbol window is detected on channel B.
3	SESB		Syntax error in symbol window channel B.
		0	No syntax error is detected.
		1	Syntax error during symbol window is detected on channel B.

Table 26-132. Symbol Window and NIT Status Register (SWNIT) Field Descriptions (continued)

Bit	Field	Value	Description
2	TCSA		Transmission conflict in symbol window channel A.
		0	No transmission conflict is detected.
		1	Transmission conflict in symbol window is detected on channel A.
1	SBSA		Slot boundary violation in symbol window channel A.
		0	No slot boundary violation is detected.
		1	Slot boundary violation during symbol window is detected on channel A.
0	SESA		Syntax error in symbol window channel A.
		0	No syntax error is detected.
		1	Syntax error during symbol window is detected on channel A.

26.3.2.4.9 Aggregated Channel Status (ACS)

The aggregated channel status provides the host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception. The aggregated channel status also includes status data from the symbol phase and the network idle time. The status data is updated (set) after each slot and aggregated until it is reset by the host. During startup the status data is not updated. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. This register is reset when the Communication Controller leaves CONFIG state or enters STARTUP state.

Figure 26-154 and Table 26-133 illustrate this register.

Figure 26-154. Aggregated Channel Status Register (ACS) [offset_CC = 128h]

Table 26-133. Aggregated Channel Status Register (ACS) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reads return 0. Writes have no effect.
12	SBVB		Slot boundary violation on channel B. One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots including symbol window and NIT).
		0	No slot boundary violation is observed.
		1	Slot boundary violation is observed on channel B.
11	CIB		Communication indicator channel B. One or more valid frames were received on channel B in slots that also contained any additional communication during the observation period, that is, one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.
		0	No valid frame is received in slots containing any additional communication.
		1	Valid frame is received on channel B in slots containing any additional communication.
10	CEDB		Content error detected on channel B. One or more frames with a content error were received on channel B in any static or dynamic slot during the observation period.
		0	No frame with content error is received.
		1	Frame with content error is received on channel B.

Copyright © 2018, Texas Instruments Incorporated

Table 26-133. Aggregated Channel Status Register (ACS) Field Descriptions (continued)

Bit	Field	Value	Description
9	SEDB		Syntax error detected on channel B. One or more syntax errors in static or dynamic slots including symbol window and NIT were observed on channel B.
		0	No syntax error is observed.
		1	Syntax error is observed on channel B.
8	VFRB		Valid frame received on channel B. One or more valid frames were received on channel B in any static or dynamic slot during the observation period. Reset is under control of the host.
		0	No valid frame is received.
		1	Valid frame is received on channel B.
7-5	Reserved	0	Reads return 0. Writes have no effect.
4	SBVA		Slot boundary violation on channel A. One or more slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots including symbol window and NIT).
		0	No slot boundary violation is observed.
		1	Slot boundary violation is observed on channel A.
3	CIA		Communication indicator channel A. One or more valid frames were received on channel A in slots that also contained any additional communication during the observation period, that is, one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.
		0	No valid frame is received in slots containing any additional communication.
		1	Valid frame is received on channel A in slots containing any additional communication.
2	CEDA		Content error detected on channel A. One or more frames with a content error were received on channel A in any static or dynamic slot during the observation period.
		0	No frame with content error is received.
		1	Frame with content error is received on channel A.
1	SEDA		Syntax error detected on channel A. One or more syntax errors in static or dynamic slots including symbol window and NIT were observed on channel A.
		0	No syntax error is observed.
		1	Syntax error is observed on channel A.
0	VFRA		Valid frame received on channel A. One or more valid frames were received on channel A in any static or dynamic slot during the observation period.
		0	No valid frame is received.
		1	Valid frame is received on channel A.

26.3.2.4.10 Even Sync ID Registers (ESID[1-15])

Registers ESID1 to ESID15 hold the frame IDs of the sync frames received in **even** communication cycles, assorted in ascending order, with register ESID1 holding the lowest received sync frame ID. If the node transmits a sync frame in an even communication cycle by itself, register ESID1 holds the respective sync frame ID as configured in message buffer 0. The value is updated during the NIT of each even communication cycle. This register is reset when the Communication Controller leaves CONFIG state or enters STARTUP state.

Figure 26-155 and Table 26-134 illustrate this register.

Figure 26-155. Even Sync ID Registers (ESIDn) [offset_CC = 130h-168h]

26.3.2.4.11 Odd Sync ID Registers (OSID[1-15])

Registers OSID1 to OSID15 hold the frame IDs of the sync frames received in **odd** communication cycles, assorted in ascending order, with register OSID1 holding the lowest received sync frame ID. If the node transmits a sync frame in an odd communication cycle by itself, register OSID1 holds the respective sync frame ID as configured in message buffer 0. The value is updated during the NIT of each odd communication cycle. This register is reset when the Communication Controller leaves CONFIG state or enters STARTUP state.

Figure 26-156 and Table 26-135 illustrate this register.

Figure 26-156. Odd Sync ID Registers (OSIDn) [offset_CC = 170h-1A8h]

26.3.2.4.12 Network Management Vector Registers (NMV[1-3])

The three network management registers hold the accrued NM vector (configurable 0-12 bytes). The accrued NM vector is generated by the communication controller by bit-wise ORing each NM vector received (valid frames with PPI = 1) on each channel.

The communication controller updates the NM vector at the end of each communication cycle as long as the communication controller is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.

NMVn-bytes exceeding the configured NM vector length are not valid.

Figure 26-157 illustrates these registers and Table 26-136 shows the assignment of the data bytes to the network management vector.

26.3.2.5 Message Buffer Control Registers

26.3.2.5.1 Message RAM Configuration (MRC)

The message RAM Configuration register defines the number of message buffers assigned to the static segment, dynamic segment, and FIFO. The register can be written during DEFAULT_CONFIG or CONFIG state only.

Figure 26-158 and Table 26-137 illustrate this register.

Figure 26-158. Message RAM Configuration Register (MRC) [offset_CC = 300h]

31	27	26	25	24	23	16
Reserved		SPLM*	SEC*		LCB*	
R-0		R-1h	R-0		R/W-80h	

15	8	7	0
FFB*		FDB*	
R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; *These bits can be updated in DEFAULT_CONFIG or CONFIG state only

Table 26-137. Message RAM Configuration Register (MRC) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26	SPLM		Sync Frame Payload Multiplex. This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1). When this bit is set to 1 message buffers 0 and 1 are dedicated for sync frame transmission with different payload data on channel A and B. When this bit is set to 0, sync frames are transmitted from message buffer 0 with the same payload data on both channels. Note that the channel filter configuration for message buffer 0 resp. message buffer 1 has to be chosen accordingly.
		0	Only message buffer 0 is locked against reconfiguration.
		1	Both message buffers 0 and 1 are locked against reconfiguration.
25-24	SEC		Secure Buffers. Not evaluated when the communication controller is in DEFAULT_CONFIG or CONFIG state.
		0	Reconfiguration of message buffers is enabled with numbers < FFBh enabled. Exception: In nodes configured for sync frame transmission or for single slot mode operation message buffer 0 (and if SPLM = 1, also message buffer 1) is always locked.
		1h	Reconfiguration of message buffers with numbers < FDB and with numbers FFB is locked and transmission of message buffers for static segment with numbers FDB is disabled.
		2h	Reconfiguration of all message buffers is locked.
		3h	Reconfiguration of all message buffers is locked and transmission of message buffers for static segment with numbers FDB is disabled.
23-16	LCB		Last configured buffer.
		0-7Fh	Number of message buffers is LCB + 1.
		≥ 80h	No message buffer is configured.
15-8	FFB		First buffer of FIFO.
		0	All message buffers are assigned to the FIFO.
		0-7Fh	Message buffers from FFB to LCB are assigned to the FIFO.
		≥ 80h	No message buffer is assigned to the FIFO.
7-0	FDB		First dynamic buffer.
		0	No group of pure static buffers is configured.
		0-7Fh	Message buffers 0 to FDB - 1 are reserved for static segment.
		≥ 80h	No dynamic buffers are configured.

Copyright © 2018, Texas Instruments Incorporated

NOTE: In case the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1), message buffer 0 resp. 1 is reserved for sync frames or single slot frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation message buffer 0 resp. 1 is treated like all other message buffers.

Table 26-138. Buffer Configuration

Message Buffer 0	↓ Static Buffers		
Message Buffer 1			
. . .	↓ Static + Dynamic Buffers	← **FDB**	
	↓ FIFO	← **FFB**	FIFO configured: FBB > FDB No FIFO configured: FFB ≥ 128
Message Buffer N-1			
Message Buffer N		← **LCB**	LCB ≥ FDB, LCB ≥ FFB

The programmer must ensure that the configuration defined by FDB(7-0), FFB(7-0), and LCB(7-0) is valid.

NOTE: The communication controller does not check for erroneous configurations.

NOTE: Maximum Number of Header Sections

The maximum number of header sections is 128. This means a maximum of 128 message buffers can be configured. The maximum length of the data sections is 254 bytes. The length of the data section may be configured different for each message buffer. In case two or more message buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "Static Buffers" or at the beginning of the "Static + Dynamic Buffers" section. The FlexRay protocol specification requires that each node has to send a frame in its key slot. Therefore at least message buffer 0 is reserved for transmission in the key slot. Due to this requirement a maximum number of 127 message buffers can be assigned to the FIFO. Nevertheless, a non protocol conform configuration without a transmission slot in the static segment would still be operational. The payload length configured and the length of the data sections need to be configured identical for all message buffers belonging to the FIFO via WRHS2. PLC and WRHS3.DP. When the communication controller is not in DEFAULT_CONFIG or CONFIG state reconfiguration of message buffers belonging to the FIFO is locked.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.5.2 FIFO Rejection Filter (FRF)

The FIFO rejection filter defines a user specified sequence of bits with which channel, frame ID, and cycle count of the incoming frames are compared. Together with the FIFO rejection filter mask (FRFM), this register determines whether a message is rejected by the FIFO. The FRF register can be written during DEFAULT_CONFIG or CONFIG state only.

Figure 26-159 and Table 26-139 illustrate this register.

Figure 26-159. FIFO Rejection Filter Register (FRF) [offset_CC = 304h]

31	25	24	23	22	16
Reserved		RNF*	RSS*	CYF*	
R-0		R-1h	R-1h	R/W-0	

15	13	12	2	1	0
Reserved		FID*		CH*	
R-0		R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; *These bits can be updated in DEFAULT_CONFIG or CONFIG state only

Table 26-139. FIFO Rejection Filter Register (FRF) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	RNF		Reject null frames. If this bit is set, received null frames are not stored in the FIFO.
		0	Null frames are stored in the FIFO.
		1	Reject all null frames.
23	RSS		Reject in static segment. If this bit is set, the FIFO is used only for the dynamic segment.
		0	FIFO also used in static segment.
		1	Reject messages in static segment.
22-16	CYF		Cycle counter filter. The 7-bit cycle counter filter determines the cycle set to which the frame ID FIFO rejection filter and the channel FIFO rejection filter are applied. In cycles not belonging to the cycle set specified by CYF, all frames are rejected. For details about the configuration of the cycle counter filter.
15-13	Reserved	0	Reads return 0. Writes have no effect.
12-2	FID	0-7FFh	Frame ID filter. A frame ID filter value of 0 means that no frame ID is rejected.
1-0	CH		Channel filter.
			Note: If reception on both channels is configured, also in the static segment both frames (from channel A and B) are always stored in the FIFO, even if they are identical.
		0	Receive on both channels.
		1h	Receive only on channel B.
		2h	Receive only on channel A.
		3h	No reception.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.5.3 FIFO Rejection Filter Mask (FRFM)

The FIFO rejection filter mask specifies which of the corresponding frame ID filter bits are relevant for rejection filtering. If a bit is set, it indicates that the state of the corresponding bit in the FRF register will not be considered for rejection filtering. The FRFM register can be written during DEFAULT_CONFIG or CONFIG state only.

Figure 26-160 and Table 26-140 illustrate this register.

Figure 26-160. FIFO Rejection Filter Mask Register (FRFM) [offset_CC = 308h]

31	16
Reserved

Reserved		MFID*		Reserved	
R-0		R/W-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; *These bits can be updated in DEFAULT_CONFIG or CONFIG state only

Table 26-140. FIFO Rejection Filter Mask Register (FRFM) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reads return 0. Writes have no effect.
12-2	MFID		Mask Frame ID Filter.
		0	Corresponding frame ID filter bit is used for rejection filtering.
		1	Ignore corresponding frame ID filter bit.
1-0	Reserved	0	Reads return 0. Writes have no effect.

26.3.2.5.4 FIFO Critical Level (FCL)

The communication controller accepts modifications of the register in DEFAULT_CONFIG or CONFIG state only.

Figure 26-161 and Table 26-141 illustrate this register.

Figure 26-161. FIFO Critical Level Register (FCL) [offset_CC = 30Ch]

31	16
Reserved	
R-0	

15	8	7	0
Reserved		CL*	
R-0		R/W-810h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; *These bits can be updated in DEFAULT_CONFIG or CONFIG state only

Table 26-141. FIFO Critical Level Register (FCL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	CL		Critical Level. When the receive FIFO fill level FSR.RFFL is equal or greater than the critical level configured by CL, the receive FIFO critical level flag FSR.RFCL is set. If CL is programmed to values > 128, bit FSR.RFCL is never set. When FSR.RFCL changes from 0 to 1 bit SIR.RFCL is set to 1, and if enabled, an interrupt is generated.

26.3.2.6 Message Buffer Status Registers

26.3.2.6.1 Message Handler Status (MHDS)

A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. A hardware reset will also clear the register.

Figure 26-162 and Table 26-142 illustrate this register.

Figure 26-162. Message Handler Status (MHDS) [offset_CC = 310h]

31	30 24	23	22 16
Rsvd	MBU	Rsvd	MBT
R-0	R-0	R-0	R-0

15	14 8	7	6	5	4	3	2	1	0
Rsvd	FMB	CRAM	MFMB	FMBD	PTFB2	PTFB1	PMR	POBF	PIBF
R-0	R-0	R-1h	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-142. Message Handler Status (MHDS) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reads return 0. Writes have no effect.
30-24	MBU	0-7Fh	Message buffer updated. Number of the message buffer that was updated last by the communication controller. For this message buffer, the respective ND and/or MBC flag in the new data 1...4 (NDAT1...4) and the message buffer status changed 1...4 (MBSC1...4) registers are also set. **Note: MBU are reset when the communication controller leaves CONFIG state or enters STARTUP state.**
23	Reserved	0	Reads return 0. Writes have no effect.
22-16	MBT	0-7Fh	Message buffer transmitted. Number of the last successfully transmitted message buffer. If the message buffer is configured for single-shot mode, the respective TXR flag in the Transmission request register 1...4 (TXRQ1..4) was reset. **Note: MBT are reset when the communication controller leaves CONFIG state or enters STARTUP state.**
15	Reserved	0	Reads return 0. Writes have no effect.
14-8	FMB	0-7Fh	Faulty message buffer. An ECC multi-bit error occurred when reading from a message buffer or when transferring data from Input Buffer or Transient Buffer 1,2 to the message buffer referenced by FMB. This value is only valid when one of the flags PIBF, PMR, PTBF1, PTBF2, and flag FMBD is set. Is not updated while flag FMBD is set.
7	CRAM		Clear all internal RAMs. Signals that execution of the controller host interface command CLEAR_RAMS is ongoing (all bits of all internal RAM blocks are written to 0). The bit is set by hardware reset or by the controller host interface command CLEAR_RAMS.
		0	No execution of the controller host interface command CLEAR_RAMS.
		1	Execution of the controller host interface command CLEAR_RAMS is ongoing.
6	MFMB		Multiple faulty message buffers detected.
		0	No additional faulty message buffer.
		1	Another faulty message buffer was detected while flag FMBD is set.
5	FMBD		Faulty message buffer detected.
		0	No faulty message buffer.
		1	Message buffer referenced by FMB holds faulty data due to an ECC multi-bit error.
4	PTBF2		ECC error transient buffer RAM B.
		0	No ECC multi-bit error.
		1	ECC multi-bit error occurred when reading transient buffer RAM B.
3	PTBF1		ECC error transient buffer RAM A.
		0	No ECC multi-bit error.
		1	ECC multi-bit error occurred when reading transient buffer RAM A.

Copyright © 2018, Texas Instruments Incorporated

Table 26-142. Message Handler Status (MHDS) Field Descriptions (continued)

Bit	Field	Value	Description
2	PMR		ECC error message RAM.
		0	No ECC multi-bit error.
		1	ECC multi-bit error occurred when reading message RAM.
1	POBF		ECC error output buffer RAM 1, 2.
		0	No ECC multi-bit error.
		1	ECC multi-bit error occurred when message handler read output buffer RAM 1,2.
0	PIBF		ECC error input buffer RAM 1, 2.
		0	No ECC multi-bit error.
		1	ECC multi-bit error occurred when message handler read input buffer RAM 1,2.

NOTE: When one of the flags PIBF, POBF, PMR, PTBF1, PTBF2 changes from 0 to 1, the PERR flag in the Error Interrupt Register (EIR) is set to 1.

26.3.2.6.2 Last Dynamic Transmit Slot (LDTS)

The register is reset when the communication controller leaves CONFIG state or enters STARTUP state Figure 26-163 and Table 26-143 illustrate this register.

Figure 26-163. Last Dynamic Transmit Slot (LDTS) [offset_CC = 314h]

Table 26-143. Last Dynamic Transmit Slot (LDTS) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26-16	LDTB		Last Dynamic Transmission Channel B. Value of Slot Counter B at the time of the last frame transmission on channel A in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to 0 if no frame was transmitted during the dynamic segment.
15-11	Reserved	0	Reads return 0. Writes have no effect.
10-0	LDTA		Last Dynamic Transmission Channel A. Value of Slot Counter A at the time of the last frame transmission on channel A in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to 0 if no frame was transmitted during the dynamic segment.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.6.3 FIFO Status Register (FSR)

The register is reset when the communication controller leaves CONFIG state, enters STARTUP state, or by CHI command CLEAR_RAMS..

Figure 26-164 and Table 26-144 illustrate this register.

Figure 26-164. FIFO Status Register (FSR) [offset_CC = 318h]

31															16
Reserved															
R-0															
15							8	7			3	2	1	0	
RFFL								Reserved				RFO	RFCL	RFNE	
R-0								R-0				R-0	R-0	R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 26-144. FIFO Status Register (FSR) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0. Writes have no effect.
15-8	RFFL	0-7Fh	Receive FIFO Fill Level. Number of FIFO buffers filled with new data not yet read by the Host.
7-7	Reserved	0	Reads return 0. Writes have no effect.
2	RFO		Receive FIFO Overrun. The flag is set by the communication controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, interrupt flag RFO in the Error Interrupt Register (EIR) is set. The flag is cleared by the next FIFO read access issued by the Host.
		0	No receive FIFO overrun is detected.
		1	A receive FIFO overrun is detected.
1	RFCL		Receive FIFO Critical Level. This flag is set when the receive FIFO fill level RFFL is equal or greater than the critical level as configured by CL in the FIFO Critical Level register (FCL). The flag is cleared by the communication controller as soon as RFFL drops below FCL.CL. When RFCL changes from 0 to 1, the RFCL flag in the Status Interrupt register (SIR) is set to 1, and if enabled, an interrupt is generated.
		0	Receive FIFO is below critical level.
		1	Receive FIFO critical level is reached.
0	RFNE		Receive FIFO Not Empty. This flag is set by the communication controller when a received valid frame (data or null frame depending on rejection mask) was stored in the FIFO. In addition, interrupt flag RFNE in the Status Interrupt register (SR) is set. The bit is reset after the Host has read all message from the FIFO.
		0	Receive FIFO is empty.
		1	Receive FIFO is not empty.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.6.4 Message Handler Constraints Flags (MHDF)

Some constraints exist for the Message Handler regarding VBUSclk frequency, Message RAM configuration, and FlexRay bus traffic. In order to simplify software development, constraints violations are reported by setting flags in the MHDF.

A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. A hardware reset will also clear the register. The register is reset when the communication controller leaves CONFIG state, enters STARTUP state, or by CHI command CLEAR_RAMS.

Figure 26-165 and Table 26-145 illustrate this register.

Figure 26-165. Message Handler Constraints Flags (MHDF) [offset_CC = 31Ch]

31	16
Reserved	
R-0	

15	9	8	7	6	5	4	3	2	1	0
Reserved		WAHP	TNSA	TNSB	TBFB	TBFA	FNFB	FNFA	SNUB	SNUA
R-0		R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-145. Message Handler Constraint Flags (MHDF) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reads return 0. Writes have no effect.
8	WAHP		Write attempt to header partition. This flag is set by the communication controller when the message handler tries to write message data into the header partition of the Message RAM due to faulty configuration of a message buffer. The write attempt is not executed, to protect the header partition from unintended write accesses.
		0	No write attempt to header partition.
		1	Write attempt to header partition.
7	TNSA		Transmission Not Started Channel A. This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot.
		0	No transmission is not started on channel A.
		1	Transmission is not started on channel A.
6	TNSB		Transmission Not Started Channel B. This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot.
		0	No transmission is not started on channel B.
		1	Transmission is not started on channel B.
5	TBFB		Transient buffer access failure B. This flag is set by the communication controller when a read or write access to TBF B requested by PRT B could not complete within the available time.
		0	No TBF B access failure.
		1	TBF B access failure.
4	TBFA		Transient buffer access failure A. This flag is set by the communication controller when a read or write access to TBF A requested by PRT A could not complete within the available time.
		0	No TBF A access failure.
		1	TBF A access failure.
3	FNFB		Find sequence not finished channel B. This flag is set by the communication controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching message buffer) with respect to channel B.
		0	No find sequence is not finished for channel B.
		1	Find sequence is not finished for channel B.
2	FNFA		Find sequence not finished channel A. This flag is set by the communication controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching message buffer) with respect to channel A.
		0	No find sequence is not finished for channel A.
		1	Find sequence is not finished for channel A.

Table 26-145. Message Handler Constraint Flags (MHDF) Field Descriptions (continued)

Bit	Field	Value	Description
1	SNUB		Status not updated channel B. This flag is set by the communication controller when the Message Handler, due to overload condition, was not able to update a message buffer's status MBS with respect to channel B.
		0	No overload condition occurred when updating MBS for channel B.
		1	MBS for channel B is not updated.
0	SNUA		Status not updated channel A. This flag is set by the communication controller when the Message Handler, due to overload condition, was not able to update a message buffer's status MBS with respect to channel A.
		0	No overload condition occurred when updating MBS for channel A.
		1	MBS for channel A is not updated.

NOTE: When one of the flags SNUA, SNUB, FNFA, FNFB, TBFA, TBFB, WAHP changes from 0 to 1, interrupt flag MHF in the Error Interrupt register (EIR) is set to 1.

26.3.2.6.5 Transmission Request Registers (TXRQ[1-4])

These four registers reflect the state of the TXR flags of all configured message buffers. The flags are evaluated for transmit buffers only. If the number of configured message buffers is less than 128, the remaining TXR flags have no meaning.

Figure 26-166 through Figure 26-169 and Table 26-146 illustrate these registers.

26.3.2.6.6 New Data Registers (NDAT[1-4])

The four registers reflect the state of the ND flags of all configured message buffers. **ND** flags corresponding to transmit buffers have no meaning. If the number of configured message buffers is less than 128, the remaining ND flags have no meaning. The registers are reset when the communication controller leaves CONFIG state or enters STARTUP state.

Figure 26-170 through Figure 26-173 and Table 26-147 illustrate these registers.

Bit	Field	Value	Description
127-0	ND[*n*]		New data.
		0	The flags are reset when the header section of the corresponding message buffer is reconfigured or when the data section has been transferred to the output buffer.
		1	The flags are set when a valid received data frame matches the message buffer's filter configuration, independent of the payload length received or the payload length configured for that message buffer. The flags are not set after reception of null frames except for message buffers belonging to the receive FIFO.

26.3.2.6.7 Message Buffer Status Changed Registers (MBSC[1-4])

The four registers reflect the state of the MBC flags of all configured message buffers. If the number of configured message buffers is less than 128, the remaining MBC flags have no meaning.

Figure 26-174 through Figure 26-177 and Table 26-148 illustrate these registers.

26.3.2.8 Input Buffer

Double buffer structure consisting of input buffer host and input buffer shadow. While the host can write to input buffer host, the transfer to the message RAM is done from input buffer shadow. The input buffer holds the header and data sections to be transferred to the selected message buffer in the message RAM. It is used to configure the message buffers in the message RAM and to update the data sections of transmit buffers.

When updating the header section of a message buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in Message Buffer Status (MBS), Message Buffer Status (MBS) is automatically reset to 0.

The header sections of message buffers belonging to the receive FIFO can only be (re)configured when the communication controller is in DEFAULT_CONFIG or CONFIG state. For those message buffers only the payload length configured and the data pointer need to be configured by bits PLC of the Write Header Section 2 (WRHS2) and by bits DP of Write Header Section 3 (WRHS3). All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

26.3.2.8.1 Write Data Section Registers (WRDS[1-64])

Holds the data words to be transferred to the data section of the addressed message buffer. The data words (DW_n) are written to the message RAM in transmission order from DW_1(byte0, byte1) to DW_{PL}(DW_{PL}= number of data words as defined by the payload length configured in PLC of the Write Header Section 2 (WRHS2).

Figure 26-180 and Table 26-152 illustrate this register.

R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-153. Write Header Section Register 1 (WRHS1) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reads return 0. Writes have no effect.
29	MBI		Message buffer interrupt. This bit enables the receive/transmit interrupt for the corresponding message buffer. After a dedicated receive buffer has been updated by the message handler, flag RXI and/or MBSI in the status interrupt register are set. After successful transmission the TXI flag in the status interrupt register is set.
		0	The corresponding message buffer interrupt is enabled.
		1	The corresponding message buffer interrupt is disabled.
28	TXM		Transmission mode. This bit is used to select the transmission mode.
		0	Continuous mode.
		1	Single-shot mode.
27	PPIT		Payload preamble indicator transmit. This bit is used to control the state of the Payload Preamble Indicator in transmit frames. If the bit is set in a static message buffer, the respective message buffer holds network management information. If the bit is set in a dynamic message buffer, the first two bytes of the payload segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay frames is not supported by the FlexRay module, but can be done by the host CPU.
		0	Payload Preamble Indicator is not set.
		1	Payload Preamble Indicator is set.
26	CFG		Message buffer configuration bit. This bit is used to configure the corresponding buffer as transmit buffer or as receive buffer. For message buffers belonging to the receive FIFO the bit is not evaluated.
		0	The corresponding buffer is configured as receive buffer.
		1	The corresponding buffer is configured as transmit buffer.
25-24	CHB, CHA	0-3h	Channel filter control. The 2-bit channel filtering field associated with each buffer serves as a filter for receive buffers and as a control field for transmit buffers. See Table 26-154 for bit descriptions. **Note: If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no frames are transmitted resp. received frames are ignored (same function as CHA = CHB = 0)**
23	Reserved	0	Reads return 0. Writes have no effect.
22-16	CYC	0-7Fh	Cycle code. The 7-bit cycle code determines the cycle set used for cycle counter filtering.
15-11	Reserved	0	Reads return 0. Writes have no effect.
10-0	FID	0-7FFh	Frame ID. Frame ID of the selected message buffer. The frame ID defines the slot number for transmission / reception of the respective message. **Note: Message buffers with frame ID = 0 are considered not valid.**

Copyright © 2018, Texas Instruments Incorporated

Table 26-154. Channel Filter Control Bit Descriptions

CHA	CHB	Transmit Buffer transmit frame on	Receive Buffer store frame received from
1	1	both channels (static segment only)	channel A or B (store first semantically valid frame, static segment only)
1	0	channel A	channel A
0	1	channel B	channel B
0	0	no transmission	ignore frame

26.3.2.8.3 Write Header Section Register 2 (WRHS2)

Figure 26-182 and Table 26-155 illustrate this register.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-155. Write Header Section Register 2 (WRHS2) Field Descriptions

Bit	Field	Value	Description
31-23	Reserved	0	Reads return 0. Writes have no effect.
22-16	PLC	0-7Fh	Payload length configured. Length of data section (number of 2-byte words) as configured by the host. During static segment the static frame data length as configured by SFDL in the MHD configuration register defines the payload length for all static frames. If the payload length configured by PLC is shorter than this value padding bytes are inserted to ensure that frames have proper physical length. The padding pattern is logical 0.
15-11	Reserved	0	Reads return 0. Writes have no effect.
10-0	CRC	0-7FFh	Header CRC. Receive Buffer: configuration not required. Transmit buffer: Header CRC calculated and configured by the host. For calculation of the header CRC the payload length of the frame send on the bus has to be considered. In static segment the payload length of all frames is configured by MHDC.SFDL.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.8.5 Input Buffer Command Mask Register (IBCM)

Configures how the message buffer in the message RAM selected by the input buffer command request register is updated. When IBF host and IBF shadow are swapped, also mask bits LHSH, LDSH, and STXRH are swapped with bits LHSS, LDSS, and STXRS to keep them attached to the respective input buffer transfer.

Figure 26-184 and Table 26-157 illustrate this register.

Figure 26-184. Input Buffer Command Mask Register (IBCM) [offset_CC = 510h]

31	19	18	17	16
Reserved		STXRS	LDSS	LHSS
R-0		R-0	R-0	R-0

15	3	2	1	0
Reserved		STXRH	LDSH	LHSH
R-0		R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-157. Input Buffer Command Mask Register (IBCM) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reads return 0. Writes have no effect.
18	STXRS		Set transmission request shadow.
		0	Reset TXR flag.
		1	Set TXR flag; transmit buffer is released for transmission (operation ongoing or finished).
17	LDSS		Load data section shadow.
		0	Data section is not updated.
		1	Data section is selected for transfer from input buffer to the message RAM (transfer ongoing or finished).
16	LHSS		Load header section shadow.
		0	Header section is not updated.
		1	Header section is selected for transfer from input buffer to the message RAM (transfer ongoing or finished).
15-3	Reserved	0	Reads return 0. Writes have no effect.
2	STXRH		Set transmission request host. If this bit is set to 1, the transmission request flag TXR for the selected message buffer is set in the transmission request registers to release the message buffer for transmission. In single-shot mode the flag is cleared by the communication controller after transmission has completed. The flags is evaluated for transmit buffers only.
		0	Reset transmission request flag.
		1	Set transmission request flag; transmit buffer is released for transmission.
1	LDSH		Load data section host.
		0	Data section is not updated.
		1	Data section is selected for transfer from input buffer to the message RAM.
0	LHSH		Load header section host.
		0	Header section is not updated.
		1	Header section is selected for transfer from input buffer to the message RAM.

26.3.2.8.6 Input Buffer Command Request Register (IBCR)

When the host writes the number of a target message buffer in the message RAM to IBRH in the input buffer command request register, IBF host and IBF shadow are swapped. In addition the message buffer numbers stored under IBRH and IBRS are also swapped.

With this write operation the IBSYS bit in the input buffer command request register is set to 1. The message handler then starts to transfer the contents of IBF shadow to the message buffer in the message RAM selected by IBRS.

While the message handler transfers the data from IBF shadow to the target message buffer in the message RAM, the host may configure the next message in the IBF host. After the transfer between IBF shadow and the message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the message RAM may be started by the host by writing the respective target message buffer number to IBRH.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF shadow to the message RAM, IBF host and IBF shadow are swapped, IBSYH is reset to 0. IBSYS remains set to 1, and the next transfer to the message RAM is started. In addition the message buffer numbers stored under IBRH and IBRS are also swapped.

Any write access to an Input Buffer Register while both IBSYS and IBSYH are set will cause the error flag IIBA in the Error Interrupt Register (EIR) to be set. In this case the Input Buffer will not be changed.

Figure 26-185 and Table 26-158 illustrate this register.

Figure 26-185. Input Buffer Command Request Register (IBCR) [offset_CC = 514h]

31	30	23	22	16

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; *These bits can be updated in DEFAULT_CONFIG or CONFIG state only

Table 26-158. Input Buffer Command Request Register (IBCR) Field Descriptions

Bit	Field	Value	Description
31	IBSYS		Input buffer busy shadow. Set to 1 after writing IBRH. When the transfer between IBF shadow and the message RAM has completed, IBSYS is set back to 0.
		0	Transfer between IBF shadow and message RAM is completed.
		1	Transfer between IBF shadow and message RAM is in progress.
30-23	Reserved	0	Reads return 0. Writes have no effect.
22-16	IBRS	0-7Fh	Input buffer request shadow. Number of the target message buffer actually updated / lately updated.
15	IBSYH		Input buffer busy host. Set to 1 by writing IBRH while IBSYS is still 1. After the ongoing transfer between IBF shadow and the message RAM has completed, the IBSYH is set back to 0.
		0	No request is pending.
		1	Request while transfer between IBF shadow and message RAM is in progress.
14-7	Reserved	0	Reads return 0. Writes have no effect.
6-0	IBRH	0-7Fh	Input buffer request host. Selects the target message buffer in the Message RAM for data transfer from Input Buffer.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.9 Output Buffer

Double buffer structure consisting of output buffer host and output buffer shadow. While the host can read from output buffer host, the transfer from the message RAM is done to output buffer shadow. The output buffer holds the header and data sections of requested message buffers transferred from the message RAM. Used to read out message buffers from the message RAM.

26.3.2.9.1 Read Data Section Registers (RDDS[1-64])

Holds the data words read from the data section of the addressed message buffer. The data words (DW_n) are read from the message RAM in reception order from DW_1(byte0, byte1) to DW_{PL}(DW_{PL}= number of data words as defined by the payload length configured in bits PLC(6-0) of the Read Header Section 2 (RDHS2)).

Figure 26-186 and Table 26-159 illustrate this register.

			Frame ID of the selected message buffer.
			Note: Message buffers with frame ID = 0 are considered not valid.

NOTE: In case the message buffer read from the message RAM belongs to the receive FIFO, FID, and CHA, CHB were updated from the received frame while CYC, CFG, PPIT, TXM, and MBI are reset to 0.

For bit description, see also Section 26.3.2.8.2.

26.3.2.9.3 Read Header Section Register 2 (RDHS2)

Figure 26-188 and Table 26-161 illustrate this register.

Figure 26-188. Read Header Section Register 2 (RDHS2) [offset_CC = 704h]

31	30	24	23	22	16
Rsvd	PLR		Rsvd	PLC	
R-0	R-0		R-0	R-0	

15	11	10	0
Reserved		CRC	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-161. Read Header Section Register 2 (RDHS2) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reads return 0. Writes have no effect.
30-24	PLR	0-7Fh	Payload length received. Payload length value updated from received frame (exception: if message buffer belongs to the receive FIFO PLR is also updated from received null frames). When a message is stored into a message buffer the following behavior with respect to payload length received and payload length configured is implemented: **PLR > PLC:**The payload data stored in the message buffer is truncated to the payload length configured if PLC even or else truncated to PLC + 1. **PLR <= PLC:** The received payload data is stored into the message buffers data section. The remaining data bytes of the data section as configured by PLC are filled with undefined data. **PLR = zero:** The message buffers data section is filled with undefined data. **PLC = zero:** Message buffer has no data section configured. No data is stored into the message buffers data section.
23	Reserved	0	Reads return 0. Writes have no effect.
22-16	PLC	0-7Fh	Payload length configured. Length of data section (number of 2-byte words) as configured by the host.
15-11	Reserved	0	Reads return 0. Writes have no effect.
10-0	CRC	0-7FFh	Header CRC. Receive buffer: Header CRC is updated from receive frame. Transmit buffer: Header CRC is calculated and configured by the host.

NOTE: The Message RAM is organized in 4-byte words. When received data is stored into a message buffer's data section, the number of 2-byte data words written into the message buffer is PLC rounded to the next even value. PLC should be configured identical for all message buffers belonging to the receive FIFO. Header 2 is updated from data frames only.

Table 26-162. Read Header Section Register 3 (RDHS3) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reads return 0. Writes have no effect.
29	RES	0-1	Reserved bit. Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.
28	PPI		Payload preamble indicator. The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.
		0	The payload segment of the received frame does not contain a network management vector or a message ID.
		1	*Static segment:* Network management vector at the beginning of the payload.
			Dynamic segment: Message ID at the beginning of the payload.
27	NFI		Null frame indicator. Is set to 1 after storage of the first received data frame.
		0	Up to now no data frame has been stored into the respective message buffer.
		1	At least one data frame has been stored into the respective message buffer.
26	SYN		Sync frame indicator. A sync frame is marked by the sync frame indicator.
		0	The received frame is not a sync frame.
		1	The received frame is a sync frame.
25	SFI		Startup frame indicator. A startup frame is marked by the startup frame indicator.
		0	The received frame is not a startup frame.
		1	The received frame is a startup frame.
24	RCI		Received on channel indicator. Indicates the channel from which the received data frame was taken to update the respective receive buffer.
		0	Frame is received on channel B.
		1	Frame is received on channel A.
23-22	Reserved	0	Reads return 0. Writes have no effect.
21-16	RCC		Receive cycle count. Cycle counter value updated from received frame.
15-11	Reserved	0	Reads return 0. Writes have no effect.
10-0	DP		Data pointer. Pointer to the first 32-bit word of the data section of the addressed message buffer in the message RAM.

NOTE: Header 3 is updated from data frames only.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.9.5 Message Buffer Status Register (MBS)

The message buffer status is updated by the communication controller with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the message buffer. The flags are updated only when the communication controller is in NORMAL_ACTIVE or NORMAL_PASSIVE state. If only one channel (A or B) is assigned to a message buffer, the channel-specific status flags of the other channel are written to 0. If both channels are assigned to a message buffer, the channel-specific status flags of both channels are updated. The message buffer status is updated only when the slot counter reached the configured frame ID and when the cycle counter filter matched. When the Host updates a message buffer via Input Buffer, all MBS flags are reset to 0 independent of which IBCM bits are set or not.

Whenever the Message Handler changes one of the flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB the respective message buffer's MBC flag in registers MBSC1/2/3/4 is set.

Figure 26-190 and Table 26-163 illustrate this register.

Figure 26-190. Message Buffer Status Register (MBS) [offset_CC = 70Ch]

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LEGEND: R = Read only; -*n* = value after reset

Table 26-163. Message Buffer Status Register (MBS) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reads return 0. Writes have no effect.
29	RESS	0-1	Reserved bit status. Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.
28	PPIS		Payload preamble indicator status. The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.
		0	The payload segment of the received frame does not contain a network management vector or a message ID.
		1	Static segment: Network management vector at the beginning of the payload Dynamic segment: Message ID at the beginning of the payload.
27	NFIS		Null frame indicator status. If set to 0, the payload segment of the received frame contains no usable data.
		0	Received frame is a null frame.
		1	Received frame is not a null frame.
26	SYNS		Sync frame indicator status. A sync frame is marked by the sync frame indicator.
		0	No sync frame is received.
		1	The received frame is a sync frame.
25	SFIS		Startup frame indicator status. A startup frame is marked by the startup frame indicator.
		0	No startup frame is received.
		1	The received frame is a startup frame.
24	RCIS		Received on channel indicator status. Indicates the channel on which the frame was received.
		0	Frame is received on channel B.
		1	Frame is received on channel A.
23-22	Reserved	0	Reads return 0. Writes have no effect.
21-16	CCS	0-3Fh	Cycle count status. Actual cycle count when status was updated.

Table 26-163. Message Buffer Status Register (MBS) Field Descriptions (continued)

Bit	Field	Value	Description
15	MTB		Frame transmitted on channel B. Indicates that this node has transmitted a data frame in the configured slot on channel B.
		0	No data frame is transmitted on channel B.
		1	Data frame is transmitted on channel B.
14	MTA		Frame transmitted on channel A. Indicates that this node has transmitted a data frame in the configured slot on channel A.
		0	No data frame is transmitted on channel A.
		1	Data frame is transmitted on channel A.
13	Reserved	0	Reads return 0. Writes have no effect.
12	MLST		Message lost. The flag is set in case the Host did not read the message before the message buffer was updated from a received data frame. Not affected by reception of null frames except for message buffers belonging to the receive FIFO. The flag is reset by a host write to the message buffer via IBF or when a new message is stored into the message buffer after the message buffers ND flag was reset by reading out the message buffer via OBF.
		0	No message is lost.
		1	Unprocessed message was overwritten.
11	ESB		Empty slot channel B. In an empty slot there is no activity on the bus. The condition is checked in static and dynamic slots.
		0	Bus activity is detected in the configured slot on channel B.
		1	No bus activity is detected in the configured slot on channel B.
10	ESA		Empty slot channel A. In an empty slot there is no activity on the bus. The condition is checked in static and dynamic slots.
		0	Bus activity is detected in the configured slot on channel A.
		1	No bus activity is detected in the configured slot on channel A.
9	TCIB		Transmission conflict indication channel B. A transmission conflict indication is set if a transmission conflict has occurred on channel B.
		0	No transmission conflict occurred on channel B.
		1	Transmission conflict occurred on channel B.
8	TCIA		Transmission conflict indication channel A. A transmission conflict indication is set if a transmission conflict has occurred on channel A.
		0	No transmission conflict occurred on channel A.
		1	Transmission conflict occurred on channel A.
7	SVOB		Slot boundary violation observed on channel B. A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B.
		0	No slot boundary violation is observed on channel B.
		1	Slot boundary violation is observed on channel B.
6	SVOA		Slot boundary violation observed on channel A. A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A.
		0	No slot boundary violation is observed on channel A.
		1	Slot boundary violation is observed on channel A.
5	CEOB		Content error observed on channel B. A content error was observed in the configured slot on channel B.
		0	No content error is observed on channel B.
		1	Content error is observed on channel B.
4	CEOA		Content error observed on channel A. A content error was observed in the configured slot on channel A.
		0	No content error is observed on channel A.
		1	Content error is observed on channel A.
3	SEOB		Syntax error observed on channel B. A syntax error was observed in the assigned slot on channel B.
		0	No syntax error is observed on channel B.
		1	Syntax error is observed on channel B.

Copyright © 2018, Texas Instruments Incorporated

Table 26-163. Message Buffer Status Register (MBS) Field Descriptions (continued)

Bit	Field	Value	Description
2	SEOA		Syntax error observed on channel A. A syntax error was observed in the assigned slot on channel A.
		0	No syntax error is observed on channel A.
		1	Syntax error is observed on channel A.
1	VFRB		Valid frame received on channel B. A valid frame indication is set if a valid frame was received on channel B.
		0	No valid frame is received on channel B.
		1	Valid frame is received on channel B.
0	VFRA		Valid frame received on channel A. A valid frame indication is set if a valid frame was received on channel A.
		0	No valid frame is received on channel A.
		1	Valid frame is received on channel A.

NOTE: The status bits RESS, PPPIS, NFIS, FYNS, SFIS and RCIS are updated from both valid data and null frames. If no valid frame was received, the previous value is maintained.

The FlexRay protocol specification requires that FTA, and FTB can only be reset by the CPU. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1.

26.3.2.9.6 Output Buffer Command Mask Register (OBCM)

Configures how the Output Buffer is updated from the message buffer in the Message RAM selected by bits OBRS of the output buffer command request register. Mask bits RDSS and RHSS are copied to the register internal storage when a Message RAM transfer is requested by OBCR.REQ. When OBF host and OBF shadow are swapped, also mask bits RDSH and RHSH are swapped with bits RDSS and RHSS to keep them attached to the respective output buffer transfer.

Figure 26-191 and Table 26-164 illustrate this register.

Figure 26-191. Output Buffer Command Mask Register (OBCM) [offset_CC = 700h]

31	18	17	16
Reserved		RDSH	RHSH
R-0		R-0	R-0

15	2	1	0
Reserved		RDSS	RHSS
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-164. Output Buffer Command Mask Register (OBCM) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads return 0. Writes have no effect.
17	RDSH		Read data section host.
		0	Data section is not read.
		1	Data section is selected for transfer from message RAM to output buffer.
16	RHSH		Read header section host.
		0	Header section is not read.
		1	Header section is selected for transfer from message RAM to output buffer.
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	RDSS		Read Data Section shadow.
		0	Data section is not read.
		1	Data section is selected for transfer from message RAM to output buffer.
0	RHSS		Read header section shadow.
		0	Header section is not read.
		1	Header section is selected for transfer from message RAM to output buffer.

NOTE: After the transfer of the header section from the message RAM to OBF shadow has completed, the message buffer status Changed flag MBS of the selected message buffer in the message buffer Changed 1,2,3,4 registers is cleared. After the transfer of the data section from the message RAM to OBF shadow has completed, the New Data flag ND of the selected message buffer in the New Data 1,2,3,4 registers is cleared.

Copyright © 2018, Texas Instruments Incorporated

26.3.2.9.7 Output Buffer Command Request Register (OBCR)

After setting bit REQ to 1 while OBSYS is 0, OBSYS is automatically set to 1, OBRS(6-0) is copied to the register internal storage, mask bits OBCM.RDSS and OBCM.RHSS are copied to register OBCM internal storage, and the transfer of the message buffer selected by OBRS(6-0) from the Message RAM to OBF Shadow is started. When the transfer between the Message RAM and OBF shadow has completed, this is signaled by setting OBSYS back to 0.

By setting bit VIEW to 1 while OBSYS is 0, OBF Host and OBF shadow are swapped. Additionally mask bits OBCM.RDSH and OBCM.RHSH are swapped with the register OBCM internal storage to keep them attached to the respective output buffer transfer. OBRH(6-0) signals the number of the message buffer currently accessible by the Host.

If bits REQ and VIEW are set to 1 with the same write access while OBSYS is 0, OBSYS is automatically set to 1 and OBF shadow and OBF host are swapped. Additionally mask bits OBCM.RDSH and OBCM.RHSH are swapped with the registers internal storage to keep them attached to the respective output buffer transfer. Afterwards OBRS(6-0) is copied to the register

internal storage, and the transfer of the selected message buffer from the Message RAM to OBF shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF host. When the current transfer between Message RAM and OBF shadow has completed, this is signaled by setting OBSYS back to 0.

Any write access to OBCR(15-8) while OBSYS is set will cause the error flag IOBA in the Error Interrupt Register to be set.

In this case the output buffer will not be changed.

Figure 26-192 and Table 26-165 illustrate this register.

Figure 26-192. Output Buffer Command Mask Register (OBCR) [offset_CC = 714h]

31	23	22	16

R-0	R-0		R/W-0	R/W-0	R-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; *These bits can be updated in DEFAULT_CONFIG or CONFIG state only

Table 26-165. Output Buffer Command Mask Register (OBCR) Field Descriptions

Bit	Field	Value	Description
31-23	Reserved	0	Reads return 0. Writes have no effect.
22-16	OBRH	0-7Fh	Output buffer request host. Number of message buffer currently accessible by the Host via RDHS[1..3], MBS, and RDDS[1..64]. By writing VIEW to 1 OBF Shadow and OBF host are swapped and the transferred message buffer is accessible by the host.
15	OBSYS		Output buffer shadow busy. Set to 1 after setting bit REQ. When the transfer between the message RAM and OBF shadow has completed, OBSYS is set back to 0.
		0	No transfer is in progress.
		1	Transfer between message RAM and OBF shadow is in progress.
14-10	Reserved	0	Reads return 0. Writes have no effect.
9	REQ		Request message RAM Transfer. Requests transfer of message buffer addressed by OBRS from message RAM to OBF shadow. Only writable while OBSYS = 0.
		0	No request.
		1	Transfer to OBF shadow is requested.
8	VIEW		View shadow buffer. Toggles between OBF shadow and OBF host. Only writable while OBSYS = 0.
		0	No action.
		1	Swap OBF shadow and OBF.

Copyright © 2018, Texas Instruments Incorporated

Table 26-165. Output Buffer Command Mask Register (OBCR) Field Descriptions (continued)

Bit	Field	Value	Description
7	Reserved	0	Reads return 0. Writes have no effect.
6-0	OBRS	0-7Fh	Output buffer request shadow. Number of source message buffer to be transferred from the message RAM to OBF shadow. If the number of the first message buffer of the receive FIFO is written to this register, the message handler transfers the message buffer addressed by the GET Index register (GIDX) to OBF shadow.

Controller Area Network (DCAN) Module

This chapter describes the controller area network (DCAN) module.

NOTE: This chapter describes a superset implementation of the DCAN module. Consult your device-specific datasheet to identify the applicability of the DMA-related features, the number of instantiations of the DCAN IP, and the number of mailboxes supported on your specific device being used.

27.1 Overview

The Controller Area Network is a high-integrity, serial, multi-master communication protocol for distributed real-time applications. This CAN module is implemented according to ISO 11898-1 and is suitable for industrial, automotive and general embedded communications.

27.1.1 Features

The DCAN module provides the following features:

Protocol

- Supports CAN protocol version 2.0 part A, B

Speed

- Bit rates up to 1 MBit/s

MailBox

- Configurable Message objects
- Individual identifier masks for each message object
- Programmable FIFO mode for message objects

High Speed MailBox Access

- DMA access to Message RAM.

Power

- Global power down and wakeup support
- Local power down and wakeup support

Debug

- Suspend mode for debug support
- Programmable loop-back modes for self-test operation
- Direct access to Message RAM in test mode
- Supports Two interrupt lines - Level 0 and Level 1

Others

- Automatic Message RAM initialization
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- CAN Rx / Tx pins configurable as general purpose IO pins
- Software module reset
- Message RAM with SECDED mechanism
- Dual clock source to reduce jitter

27.1.2 Functional Description

The CAN protocol is an ISO standard (ISO 11898) for serial data communication. This protocol uses Non-Return To Zero (NRZ) with bit-stuffing. And the communication is carried over a two-wire balanced signaling scheme.

The DCAN data communication happens through the CAN_TX and CAN_RX pins. An additional transceiver hardware is required for the connection to the physical layer (CAN bus) CAN_High and CAN_Low.

The DCAN register set can be accessed directly by the CPU. These registers are used to control and configure the CAN module and the Message RAM.

Individual CAN message objects should be configured for communication over a CAN network. The message objects and identifier masks are stored in the Message RAM.

Copyright © 2018, Texas Instruments Incorporated

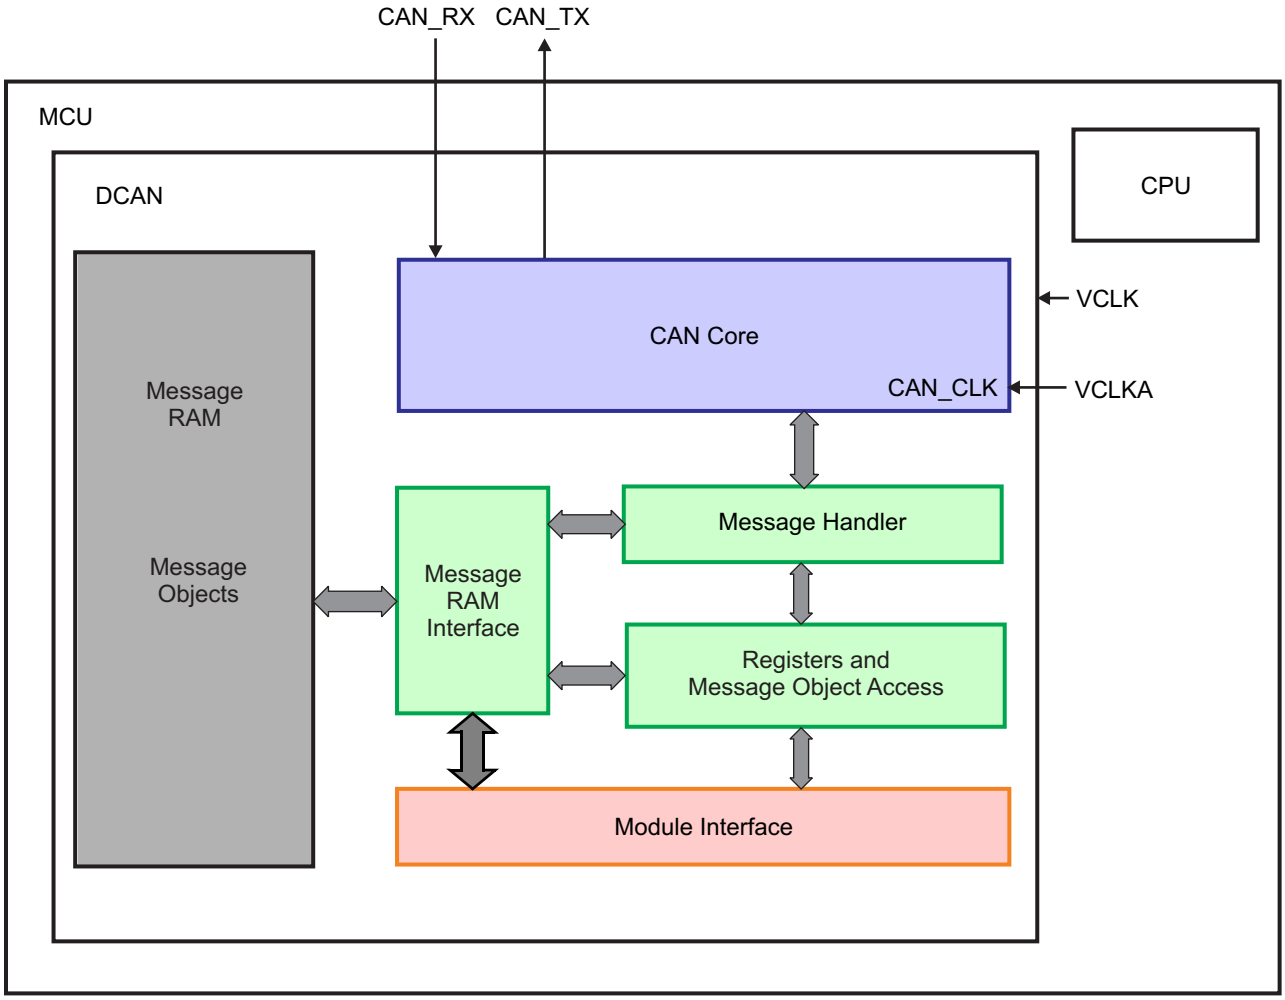
The CAN module internally handles functions such acceptance filtering, transfer of messages from and to the Message RAM, handling of transmission requests as well as the generation of interrupts or DMA requests.

27.2 CAN Blocks

The DCAN Module, shown in Figure 27-1, comprises of the following basic blocks.

27.2.1 CAN Core

The CAN Core consists of the CAN Protocol Controller and the Rx/Tx Shift Register. It handles all ISO 11898-1 protocol functions.



27.2.2 Message RAM

The DCAN Message RAM enables storage of CAN messages. Actual Device datasheet provides the details of the Message RAM address.

27.2.3 Message Handler

The Message Handler is a state machine that controls the data transfer between the single ported Message RAM and the CAN Core's Rx/Tx Shift Register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

Figure 27-1. DCAN Block Diagram

Copyright © 2018, Texas Instruments Incorporated

27.2.4 Message RAM Interface

The Interface Register sets control the CPU read and write accesses to the Message RAM. There are three interface registers IF1, IF2, and IF3:

- IF1 and IF2 Interface Registers sets for read and write access.
- IF3 Interface Register set for read access only.

The Interface Registers have the same word-length as the Message RAM. Additional information can be found in Section 27.6.

27.2.5 Register and Message Object Access

During normal operation, data consistency of the message objects is guaranteed by indirectly accessing the message objects through the interface registers IF1 and IF2.

In order to be able to perform tests on the message object memory, a dedicated test mode has been implemented, that allows direct access by either the CPU or DMA. During normal operation direct access has to be avoided.

27.2.6 Dual Clock Source

Two clock domains are provided to the DCAN module:

1. VCLK - The peripheral synchronous clock domain as the general module clock source.
2. VCLKA - The peripheral asynchronous clock source domain provided to the CAN core as clock source (CAN_CLK) for generating the CAN Bit Timing.

If a frequency modulated clock output from FMPLL is used as the VCLK source, then VCLKA should be derived from an unmodulated clock source (for example, OSCIN source).

The clock source for VCLKA is selected by the Peripheral Asynchronous Clock Source Register in the system module.

Both clock domains can be derived from the same clock source (so that VCLK = VCLKA). However, if frequency modulation in the FMPLL is enabled (spread spectrum clock), then due to the high precision clocking requirements of the CAN Core, the FMPLL clock source should not be used for VCLKA. Alternatively, a separate clock without any modulation (for example, derived directly from the OSCIN clock) should be used for VCLKA.

Refer to the system module reference guide and the device datasheet for more information how to configure the relevant clock source registers in the system module.

Between the two clock domains, a synchronization mechanism is implemented in the DCAN module in order to ensure correct data transfer.

NOTE: If the dual clock functionality is used, then VCLK must always be higher or equal to CAN_CLK (derived from the asynchronous clock source), in order to achieve a stable functionality of the DCAN. Here also the frequency shift of the modulated VCLK has to be considered:

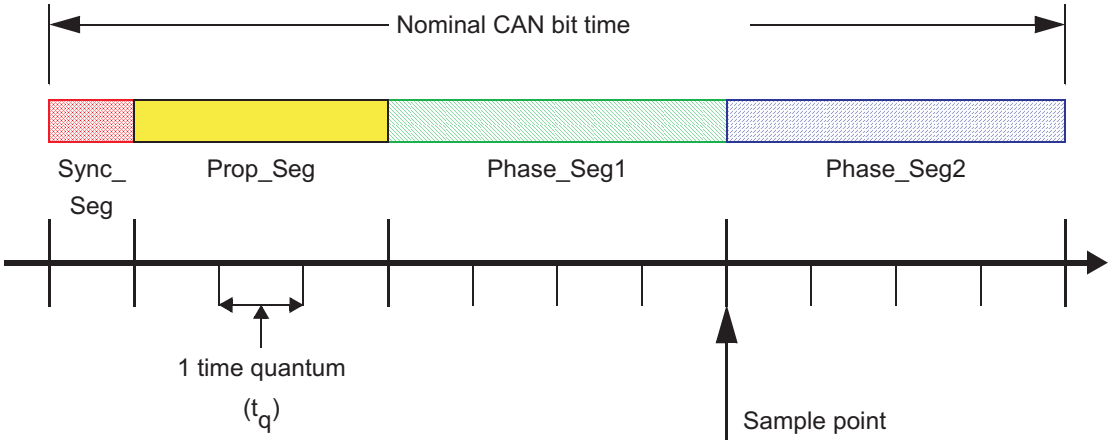
$$f_{0,\ VCLK} \pm \Delta f_{FM,VCLK} \geq f_{CANCLK}$$

The CAN Core has to be programmed to at least 8 clock cycles per bit time. To achieve a transfer rate of 1 MBaud when using the asynchronous clock domain as the clock source for CAN_CLK, an oscillator frequency of 8MHz or higher has to be used.

Copyright © 2018, Texas Instruments Incorporated

27.3 CAN Bit Timing

The DCAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.



Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The Bit timing parameters can be configured individually for each CAN node, creating a common Bit rate even though the CAN nodes' oscillator periods (f_{osc}) may be different.

27.3.1 Bit Time and Bit Rate

According to the CAN specification, the Bit time is divided into four segments (see Figure 27-2):

- Synchronization Segment (Sync_Seg)
- Propagation Time Segment (Prop_Seg)
- Phase Buffer Segment 1 (Phase_Seg1)
- Phase Buffer Segment 2 (Phase_Seg2)

Figure 27-2. Bit Timing

Each segment consists of a specific number of time quanta. The length of one time quantum, (t_q), which is the basic time unit of the bit time, is given by the CAN_CLK and the Baud Rate Prescalers (BRPE and BRP). With these two Baud Rate Prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler / CAN_CLK

Apart from the fixed length of the synchronization segment, these numbers are programmable.

Table 27-1 describes the minimum programmable ranges required by the CAN protocol. A given bit rate may be met by different Bit time configurations.

NOTE: For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Table 27-1. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to CAN_CLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either Phase Buffer Segment

Copyright © 2018, Texas Instruments Incorporated

27.3.1.1 Synchronization Segment

The Synchronization Segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

27.3.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

27.3.1.3 Phase Buffer Segments and Synchronization

The Phase Buffer Segments (Phase_Seg1 and Phase_Seg2) and the Synchronization Jump Width (SJW) are used to compensate for the oscillator tolerance.

The Phase Buffer Segments surround the sample point. The Phase Buffer Segments may be lengthened or shortened by synchronization.

The Synchronization Jump Width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg, otherwise its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

27.3.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1-df) \times f_{nom} \leq f_{osc} \leq (1+df) \times f_{nom} \quad (35)$$

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \leq \frac{\min(\text{Phase\_Seg1}, \text{Phase\_Seg2})}{[2 \times (13 \times \text{bit\_time} - \text{Phase\_Seg2})]}$$

$$\text{II:} \quad df \leq \frac{\text{SJW}}{20 \times \text{bit\_time}} \quad (36)$$

It has to be considered that SJW may not be larger than the smaller of the Phase Buffer Segments and that the Propagation Time Segment limits that part of the bit time that may be used for the Phase Buffer Segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 μs) with a bus length of 40 m.

Copyright © 2018, Texas Instruments Incorporated

27.3.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of 4 bits (BREP) is provided. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte

In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1… n], values in the range of [0 … n-1] are programmed. That way, SJW (functional range of [1 … 4]) is represented by only two bits.

Therefore the length of the Bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the Bit Timing Register (BTR) is the configuration input of the CAN protocol controller. The Baud Rate Prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the Bit Timing Logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

27.3.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting Bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

NOTE: 8 MHz is the minimum CAN clock frequency required to operate the DCAN at a bit rate of 1 MBit/s.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the Baud Rate Prescaler with t_q = (Baud Rate Prescaler) / CAN_CLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0 … 2] t_q.

The length of the Synchronization Jump Width is set to its maximum value, which is the minimum of 4 and Phase_Seg1.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration that allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

Copyright © 2018, Texas Instruments Incorporated

The resulting configuration is written into the Bit Timing Register:

Tseg2 = Phase_Seg2 - 1
Tseg1 = Phase_Seg1 + Prop_Seg - 1
SJW = SynchronizationJumpWidth - 1
BRP = Prescaler - 1

27.3.2.2 Calculation of BRP Values

If Baud and CAN_CLK(VCLK) are already known, the BRP/BRPE values need to be calculated to be programmed into the register. It is calculated using the following equation:

BRP = CAN_CLK / (BAUD)(1 + TSEG1 + TSEG2) (37)

27.3.2.3 Example for Bit Timing at High Baudrate

In this example, the frequency of CAN_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

t_q	100	ns	=	t_{CAN_CLK}
delay of bus driver	60	ns		
delay of receiver circuit	40	ns		
delay of bus line (40m)	220	ns		
t_{Prop}	700	ns	=	INT (2 × delays + 1) = 7 • t_q
t_{SJW}	100	ns	=	1 × t_q
t_{TSeg1}	800	ns	=	t_{Prop} + t_{SJW}
t_{TSeg2}	100	ns	=	Information Processing Time + 1 • t_q
$t_{Sync\text{-}Seg}$	100	ns	=	1 × t_q
bit time	1000	ns	=	$t_{Sync\text{-}Seg}$ + t_{TSeg1} + t_{TSeg2}
tolerance for CAN_CLK	1.58	%	=	$\frac{\min(TSeg1, TSeg2)}{[2 \times (13 \times bit\_time - TSeg2)]}$ (38)
			=	$\frac{0.1\mu s}{[2 \times (13 \times 1\mu s - 0.1\mu s)]}$ (39)
			=	0.38%

In this example, the concatenated bit time parameters are $(1\text{-}1)_3$ & $(8\text{-}1)_4$ & $(1\text{-}1)_2$ & $(1\text{-}1)_6$, so the Bit Timing Register is programmed to 0000 0700h.

Copyright © 2018, Texas Instruments Incorporated

27.3.2.4 Example for Bit Timing at Low Baudrate

In this example, the frequency of CAN_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

t_q	1	µs	=	$2 \times t_{CAN\_CLK}$
delay of bus driver	200	ns		
delay of receiver circuit	80	ns		
delay of bus line (40m)	220	ns		
t_{Prop}	1	µs	=	$1 \times t_q$
t_{SJW}	4	µs	=	$4 \times t_q$
t_{TSeg1}	5	µs	=	$t_{Prop} + t_{SJW}$
t_{TSeg2}	3	µs	=	Information Processing Time + $3 \times t_q$
$t_{Sync\text{-}Seg}$	1	µs	=	$1 \times t_q$
bit time	9	µs	=	$t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$
tolerance for CAN_CLK	0.43	%	=	$\frac{\min(TSeg1, TSeg2)}{[2 \times (13 \times bit\_time - TSeg2)]}$ (40)
			=	$\frac{3\mu s}{[2 \times (13 \times 9\mu s - 3\mu s)]}$ (41)
			=	1.32%

In this example, the concatenated bit time parameters are $(3\text{-}1)_3$ & $(5\text{-}1)_4$ & $(4\text{-}1)_2$ & $(2\text{-}1)_6$, so the Bit Timing Register is programmed to 0000 24C1h.

27.4 CAN Module Configuration

After a hardware reset all CAN protocol functions are disabled.The CAN module must be initialized and configured before it can participate on the CAN bus.

27.4.1 DCAN RAM Initialization Through Hardware

To start with a clean DCAN RAM ,the complete DCAN RAM has to be initialized with zeros and the ECC bits set accordingly by configuring the following registers in the system module:

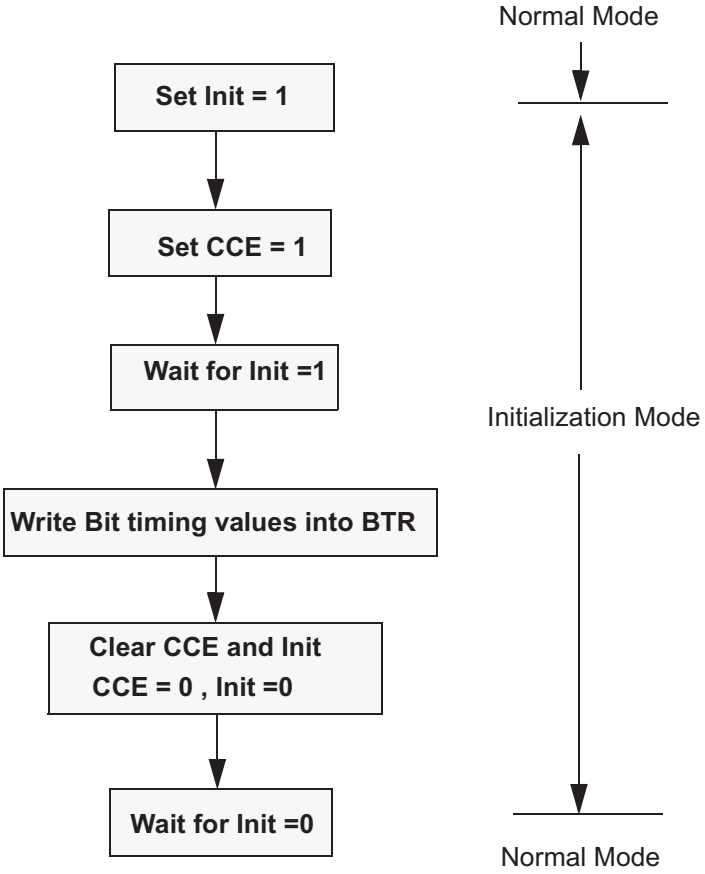
1. Memory Hardware Initialization Global Control Register (MINITGCR)
2. Memory Initialization Enable Register (MSINENA)

For more details on RAM hardware initialization support, refer to the system module reference guide.

27.4.2 CAN Module Initialization

To initialize the CAN Controller, you have to set up the CAN Bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

So the two critical steps are:



1. Configuration of CAN Bit Timings
2. Configuration of Message Objects

27.4.2.1 Software Configuration of CAN Bit Timings

This step involves configuring the CAN baud rate register with the calculated CAN bit timing value. The calculation procedure of CAN bit timing values for BTR register are mentioned in Section 27.3. Refer to Figure 27-3 for CAN bit timing software configuration flow.

Copyright © 2018, Texas Instruments Incorporated

Figure 27-3. CAN Bit-timing Configuration

Step 1: Enter “initialization mode” by setting the Init (Initialization) bit in the CAN Control Register.

While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

Also note that the CAN module is also in initialization mode on hardware reset and during Bus-Off.

Step 2: Set the CCE (Configure Change Enable) bit in the CAN Control Register.

The access to the Bit Timing Register for the configuration of the Bit timing is enabled when both Init and CCE bits in the CAN Control Register are set.

Step 3: Wait for the Init bit to get set. This would make sure that the module has entered “Initialization mode”.

Step 4: Write the Bit-Timing values into the Bit-Timing Register (BTR).

Refer to Section 27.3.2.1 for BTR value calculation for a given bit-timing.

Step 5: Clear the CCE bit followed by Init bit.

Step 6: Wait for the Init bit to clear. This would make sure that the module has come out of “initialization mode”.

After step 6 (Init bit cleared), the module will attempt a synchronization on the CAN bus, provided that the BTR settings are meeting the CAN bus parameters.

Copyright © 2018, Texas Instruments Incorporated

NOTE: The module would not come out of the “initialization mode” if any incorrect BTR values are written in step 4.

27.4.2.2 Configuration of Message Objects

The whole Message RAM should be configured before putting the CAN into operation. All the message objects are deactivated by default. You should configure the message object that are to be used to a particular identifier. you can change the configuration of any message object or deactivate it when required.

The message objects can be configured only through the Interface registers (IFx) and the CPU does not have direct access to the message object (Message RAM) when DCAN is in operation.

To configure the message objects, you must know about:

1. The message object structure (Section 27.5)
2. The interface register set (IFx) (Section 27.6)

NOTE: The message objects initialization is independent of the bit-timing configuration procedure.

Copyright © 2018, Texas Instruments Incorporated

27.5 Message RAM

The DCAN Message RAM contains message objects and ECC bits for the message objects.

27.5.1 Structure of Message Objects

Figure 27-4 shows the structure of a message object.

The grayed fields are those parts of the message object that are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Figure 27-4. Structure of a Message Object

Message Object												
UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 27-2. Message Object Field Descriptions

Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the Message Handler.
	1	The message object is to be used by the Message Handler.
		Note: The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit Init in the CAN Control Register. MsgVal must also be reset if the messages object is no longer used in operation. For reconfiguration of message objects during normal operation see Section 27.7.6 and Section 27.7.7.
UMask		Use Acceptance Mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to 1, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to 1.
ID[28:0]		Message Identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits
Msk[28:0]		Identifier Mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Extended Identifier
	0	The 11-bit ("standard") identifier will be used for this message object.
	1	The 29-bit ("extended") identifier will be used for this message object.
MXtd		Mask Extended Identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit ("standard") identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message Direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).
MDir		Mask Message Direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.

Copyright © 2018, Texas Instruments Incorporated

Table 27-2. Message Object Field Descriptions (continued)

Name	Value	Description
EOB		End of Block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to 1.
NewDat		New Data
	0	No new data has been written into the data bytes of this message object by the Message Handler since the last time when this flag was cleared by the CPU.
	1	The Message Handler or the CPU has written new data into the data bytes of this message object.
MsgLst		Message Lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the CPU.
	1	The Message Handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive Interrupt Enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit Interrupt Enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt Pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register will point to this message object if there is no other interrupt source with higher priority.
RmtEn		Remote Enable
	0	At the reception of a Remote Frame, TxRqst is not changed.
	1	At the reception of a Remote Frame, TxRqst is set.
TxRqst		Transmit Request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data Length Code
	0-8	Data Frame has 0-8 data bytes.
	9-15	Data Frame has 8 data bytes.
		Note: The Data Length Code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the Message Handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN Data Frame
Data 1		2nd data byte of a CAN Data Frame
Data 2		3rd data byte of a CAN Data Frame
Data 3		4th data byte of a CAN Data Frame
Data 4		5th data byte of a CAN Data Frame
Data 5		6th data byte of a CAN Data Frame
Data 6		7th data byte of a CAN Data Frame
Data 7		8th data byte of a CAN Data Frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN Core during a reception, byte Data 7 is the last. When the Message Handler stores a data frame, it will write all the eight data bytes into a message object. If the Data Length Code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

Copyright © 2018, Texas Instruments Incorporated

27.5.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:

Message RAM base address + (message object number) × 0x20.

This means that Message Object 1 starts at offset 0x0020; Message Object 2 starts at offset 0x0040, and so on.

NOTE: 0 is not a valid message object number. At address 0x0000, message object number 64 is located. Writing to the address of an unimplemented message object may overwrite an implemented message object.

The base address for DCAN1 RAM is FF1E 0000h, DCAN2 RAM is FF1C 0000h, DCAN3 RAM is FF1A 0000h, and DCAN4 RAM base address is FF18 0000h.

Message Object number 1 has the highest priority.

Table 27-3. Message RAM Addressing in Debug/Suspend and RDA Mode

Message Object Number	Base Address Offset	Word Number	Debug/Suspend mode, see Section 27.5.3	RDA mode, see Section 27.5.4

27.5.3 Message RAM Representation in Debug/Suspend Mode

In Debug/Suspend mode, the Message RAM will be memory mapped. This allows the external debug unit to access the Message RAM.

NOTE: During Debug/Suspend Mode, the Message RAM cannot be accessed via the IFx register sets.

Figure 27-5. Message RAM Representation in Debug/Suspend Mode

Bit	31 15	30 14	29 13	28 12	27 11	26 10	25 9	24 8	23 7	22 6	21 5	20 4	19 3	18 2	17 1	16 0

	Data 1								Data 0							
MsgAddr + 0x14	Data 7								Data 6							
	Data 5								Data 4							

27.5.4 Message RAM Representation in Direct Access Mode

When the RDA bit in Test Register is set while the DCAN module is in Test Mode (Test bit in CAN control register is set), the CPU has direct access to the Message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The CPU has access to one word line at a time only.

In RAM Direct Access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the Message RAM base address.

NOTE: During Direct Access Mode, the Message RAM cannot be accessed via the IFx register sets. Before entering RDA mode, it must be ensured that the Init bit is set to avoid any conflicts with the message handler accessing the message RAM.

Any read or write to the RAM addresses for RamDirectAccess during normal operation mode (TestMode bit or RDA bit is not set) will be ignored.

Writes to Reserved bits have no effect.

Figure 27-6. Message RAM Representation in RAM Direct Access Mode

Bit	31 15	30 14	29 13	28 12	27 11	26 10	25 9	24 8	23 7	22 6	21 5	20 4	19 3	18 2	17 1	16 0

27.5.5 ECC RAM

On devices with SECDED implementation for the message RAM, the ECC bits are stored in a dedicated ECC RAM area that is memory-mapped as follows: The location of the ECC bits for a particular message object in RAM is: Message RAM base address + 0x1000 + (message object number) * 0x20.

NOTE: A 0 is not a valid message object number. At address 0x1000, the ECC bits of the last implemented message object are located.

As shown in Figure 27-7, the ECC bits for the last implemented Message Object (here: 128) are located at offset 0x1000; the ECC bits for Message Object 1 are located at offset 0x1020, and the ECC bits for Message Object 127 are located at offset 0x1FE0. The ECC RAM is only memory mapped if SECDED diagnostic mode is enabled.

Figure 27-7. ECC RAM Representation

Bit	31 15	30 14	29 13	28 12	27 11	26 10	25 9	24 8	23 7	22 6	21 5	20 4	19 3	18 2	17 1	16 0

27.6 Message Interface Register Sets

Accesses to the Message RAM are performed via the Interface Register sets:

- Interface Register 1 and 2 (IF1 and IF2)
- Interface Register 3 (IF3)

The IF3 register set can be configured to automatically receive control and user data from the Message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from Message RAM to IF3 register set.

The Message Handler avoids potential conflicts between concurrent accesses to Message RAM and CAN frame reception/transmission.

There are two modes where the Message RAM can be directly accessed by the CPU:

1. In Debug/Suspend mode (see Section 27.5.3)
2. In RAM Direct Access (RDA) mode (see Section 27.5.4)

For the Message RAM Base address, refer to the device datasheet.

A complete message object (see Section 27.5.1) or parts of the message object may be transferred between the Message RAM and the IF1/IF2 Register set (see Section 27.17.24) in one single transfer.

27.6.1 Message Interface Register Sets 1 and 2

The Interface Register sets IF1 and IF2 provide indirect read/write access from the CPU to the Message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

Table 27-4. Message Interface Register Sets 1 and 2

Address	IF1 Register Set		Address	IF2 Register Set	
[CAN Base +]	31 16	15 0	[CAN Base +]	31 16	15 0

27.6.2 Using Message Interface Register Sets 1 and 2

The Command Register addresses the desired message object in the Message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] of the Command Register.

When the CPU initiates a data transfer between the IF1/IF2 Registers and Message RAM, the Message Handler sets the Busy bit in the respective Command Register to '1'. After the transfer has completed, the Busy bit is set back to '0' (see Figure 27-8).

Figure 27-8. Data Transfer Between IF1 / IF2 Registers and Message RAM

Copyright © 2018, Texas Instruments Incorporated

27.6.3 Message Interface Register 3

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently.

Table 27-5. Message Interface Register 3

Address	IF3 Register Set	
[CAN Base +]	31 16	15 0
0x140	reserved	IF3 Observation
0x144	IF3 Mask 2	IF3 Mask 1
0x148	IF3 Arbitration 2	IF3 Arbitration 1
0x14C	reserved	IF3 Message Control
0x150	IF3 Data A 2	IF3 Data A 1
0x154	IF3 Data B 2	IF3 Data B 1
:	:	:
0x160	IF3 Update Enable 2	IF3 Update Enable 1
0x164	IF3 Update Enable 4	IF3 Update Enable 3
0x168	IF3 Update Enable 6	IF3 Update Enable 5
0x16C	IF3 Update Enable 8	IF3 Update Enable 7

The automatic update functionality can be programmed for each message object (see IF3 Update Enable Register, Section 27.17.33).

All valid message objects in Message RAM that are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in CAN Control register. Please refer to the device datasheet to find out if this DMA source is available.

NOTE: The IF3 register set can not be used for transferring data into message objects.

Copyright © 2018, Texas Instruments Incorporated

27.7 Message Object Configurations

This section describes the possible message object configurations for CAN communication.

27.7.1 Configuration of a Transmit Object for Data Frames

Figure 27-9 shows how a Transmit Object can be initialized.

Figure 27-9. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The Arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit Identifier (Standard Frame) is used (Xtd = 0), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The Data Registers (DLC[3:0] and Data0-7) are given by the application, TxRqst and RmtEn should not be set before the data is valid.

If the TxIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received Remote Frame will cause the TxRqst bit to be set; the Remote Frame will autonomously be answered by a Data Frame.

The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = 1) to allow groups of Remote Frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 27.8.8. Identifier masking must be disabled (UMask = 0) if no Remote Frames are allowed to set the TxRqst bit (RmtEn = 0).

27.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure Transmit Objects for the transmission of Remote Frames. Setting TxRqst for a Receive Object will cause the transmission of a Remote Frame with the same identifier as the Data Frame for which this receive Object is configured.

27.7.3 Configuration of a Single Receive Object for Data Frames

Figure 27-10 shows how a Receive Object for Data Frames can be initialized.

Figure 27-10. Initialization of a Single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The Arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used (Xtd = 0), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a Data Frame with an 11-bit Identifier is received, ID[17:0] will be set to 0.

The Data Length Code (DLC[3:0]) is given by the application. When the Message Handler stores a Data Frame in the message object, it will store the received Data Length Code and eight data bytes. If the Data Length Code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of Data Frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration Register will be overwritten by the bits of the stored Data Frame.

If the RxIE bit is set, the IntPnd bit will be set when a received Data Frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a Remote Frame with the same identifier as actually stored in the Arbitration bits will be triggered. The content of the Arbitration bits may change if the Mask bits are used (UMask = 1 for acceptance filtering.

Copyright © 2018, Texas Instruments Incorporated

27.7.4 Configuration of a Single Receive Object for Remote Frames

Figure 27-11 shows how a Receive Object for Remote Frames can be initialized.

Figure 27-11. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

Receive Objects for Remote Frames may be used to monitor Remote Frames on the CAN bus. The Remote Frame stored in the Receive Object will not trigger the transmission of a Data Frame. Receive Objects for Remote Frames may be expanded to a FIFO buffer, see Section 27.7.5.

UMask must be set to 1. The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to “must-match” or to “don’t care”, to allow groups of Remote Frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 27.8.8.

The Arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received Remote Frames. If some bits of the Mask bits are set to “don’t care”, the corresponding bits of the Arbitration bits will be overwritten by the bits of the stored Remote Frame. If an 11-bit Identifier (Standard Frame) is used (Xtd = 0), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a Remote Frame with an 11-bit Identifier is received, ID[17:0] will be set to 0.

The Data Length Code (DLC[3:0]) may be given by the application. When the Message Handler stores a Remote Frame in the message object, it will store the received Data Length Code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received Remote Frame is accepted and stored in the message object.

27.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of Receive Objects belonging to a FIFO Buffer is the same as the configuration of a single Receive Object.

To concatenate multiple message objects to a FIFO Buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO Buffer. The EoB bit of all message objects of a FIFO Buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

27.7.6 Reconfiguration of Message Objects for the Reception of Frames

A message object with Dir = ‘0’ is configured for the reception of data frames, with Dir = ‘1’ AND Umask = ‘1’ AND RmtEn = ‘0’ it is configured for the reception of remote frames.

It is necessary to reset MsgVal to not valid before changing any of the following configuration and control bits: ID[28:0], Xtd, Dir, DLC[3:0], RxIE, TxIE, RmtEn, EoB, Umask, Msk[28:0], MXtd, and MDir.

These parts of a message object may be changed without clearing MsgVal: Data[7:0], TxRqst, NewDat, MsgLst, and IntPnd.

27.7.7 Reconfiguration of Message Objects for the Transmission of Frames

A message object with Dir = ‘1’ AND (Umask = ‘0’ OR RmtEn = ‘1’) is configured for the transmission of data frames.

It is necessary to reset MsgVal to not valid before changing any of the following configuration and control bits: Dir, RxIE, TxIE, RmtEn, EoB, Umask, Msk[28:0], MXtd, and MDir

These parts of a message object may be changed without clearing MsgVal: ID[28-0], Xtd, DLC[3:0], Data[7:0], TxRqst, NewDat, MsgLst, and IntPnd.

Copyright © 2018, Texas Instruments Incorporated

27.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects.

The application has to update the data of the messages to be transmitted and enable and request their transmission. The transmission is requested automatically when a matching Remote Frame is received.

The application may read messages that are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read based on interrupts or by polling.

27.8.1 Message Handler Overview

The Message Handler state machine controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM. It performs the following tasks:

- Data Transfer from Message RAM to CAN Core (messages to be transmitted).
- Data Transfer from CAN Core to the Message RAM (received messages).
- Data Transfer from CAN Core to the Acceptance Filtering unit.
- Scanning of Message RAM for a matching message object (acceptance filtering).
- Scanning the same message object after being changed by IF1/IF2 registers when priority is same or higher as message the object found by last scanning.
- Handling of TxRqst flags.
- Handling of interrupt flags.

The Message Handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request flags
- New Data flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting the listed status information of each message object via IFx registers separately, these Message Handler registers provides a fast and easy way to get an overview (for example, about all pending transmission requests).

All Message Handler registers are read-only.

27.8.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object, so messages with the highest priority can be placed in the message objects with the lowest numbers.

The acceptance filtering for received Data Frames or Remote Frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher Message Number. The last message object may be configured to accept any Data Frame or Remote Frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

Copyright © 2018, Texas Instruments Incorporated

27.8.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN Core is ready for loading and if there is no data transfer between the IFx Registers and Message RAM, the d bits in the Message Valid Register and the TxRqst bits in the Transmission Request Register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the Message Handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If Automatic Retransmission mode is disabled by setting the DAR bit in the CAN Control Register, the behavior of bits TxRqst and NewDat in the Message Control Register of the Interface Register set is as follows:

- When a transmission starts, the TxRqst bit of the respective Interface Register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received Remote Frames do not require a Receive Object. They will automatically trigger the transmission of a Data Frame, if in the matching Transmit Object the RmtEn bit is set.

27.8.4 Updating a Transmit Object

The CPU may update the data bytes of a Transmit Object any time via the IF1/IF2 Interface Registers, neither d nor TxRqst have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A Register or IF1/IF2 Data B Register have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 Data Register or the message object is transferred to the IF1/IF2 Data Register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the Command Register and then the number of the message object is written to bits [7:0] of the Command Register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 27.8.3.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

27.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the Transmit Objects may be managed dynamically. The CPU can write the whole message (Arbitration, Control, and Data) into the Interface Register. The bits [23:16] of the Command Register can be set to 0xB7 for the transfer of the whole message object content into the message object. Before changing the configuration of a message object, MsgVal has to be reset (see Section 27.7.7).

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the Command Register should be set to 0x87.

Copyright © 2018, Texas Instruments Incorporated

NOTE: After the update of the Transmit Object, the Interface Register set will contain a copy of the actual contents of the object, including the part that had not been updated.

27.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the shift register of the CAN Core, the Message Handler starts to scan of the Message RAM for a matching valid message object:

- The Acceptance Filtering unit is loaded with the arbitration bits from the CAN Core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of Message Object 1 are loaded into the Acceptance Filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the Message RAM is reached.
- If a match occurs, the scanning is stopped and the Message Handler proceeds depending on the type of the frame (Data Frame or Remote Frame) received.

27.8.7 Reception of Data Frames

The Message Handler stores the message from the CAN Core shift register into the respective message object in the Message RAM. Not only the data bytes, but all arbitration bits and the Data Length Code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the Interrupt Register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a Remote Frame, while the requested Data Frame has just been received.

27.8.8 Reception of Remote Frames

When a Remote Frame is received, three different configurations of the matching message object have to be considered:

1. Dir = 1 (direction = transmit), RmtEn = 1, UMask = 1 or 0: The TxRqst bit of this message object is set at the reception of a matching Remote Frame. The rest of the message object remains unchanged.
2. Dir = 1 (direction = transmit), RmtEn = 0, UMask = 0: The Remote Frame is ignored, this message object remains unchanged.
3. Dir = 1 (direction = transmit), RmtEn = 0, UMask = 1: The Remote Frame is treated similar to a received Data Frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the Message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

27.8.9 Reading Received Messages

The CPU may read a received message any time via the IFx Interface Registers, the data consistency is guaranteed by the Message Handler state machine.

Typically the CPU will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the Command Register. That combination will transfer the whole received message from the Message RAM into the Interface Register set. Additionally, the bits NewDat and IntPnd are cleared in the Message RAM (not in the Interface Register set). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

Copyright © 2018, Texas Instruments Incorporated

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message have been received since the last time when this message object was read. MsgLst will not be automatically reset.

27.8.10 Requesting New Data for a Receive Object

By means of a Remote Frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a Remote Frame with the receive object's identifier. This Remote Frame triggers the other CAN node to start the transmission of the matching Data Frame. If the matching Data Frame is received before the Remote Frame could be transmitted, the TxRqst bit is automatically reset.

Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the Command Register.

27.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO Buffers. Each FIFO Buffer configured to store received messages with a particular (group of) Identifier(s). Arbitration and Mask Registers of the FIFO Buffer's message objects are identical. The EoB (End of Buffer) bits of all but the last of the FIFO Buffer's message objects are '0', in the last one the EoB bit is 1.

Received messages with identifiers matching to a FIFO Buffer are stored into a message object of this FIFO Buffer, starting with the message object with the lowest message number.

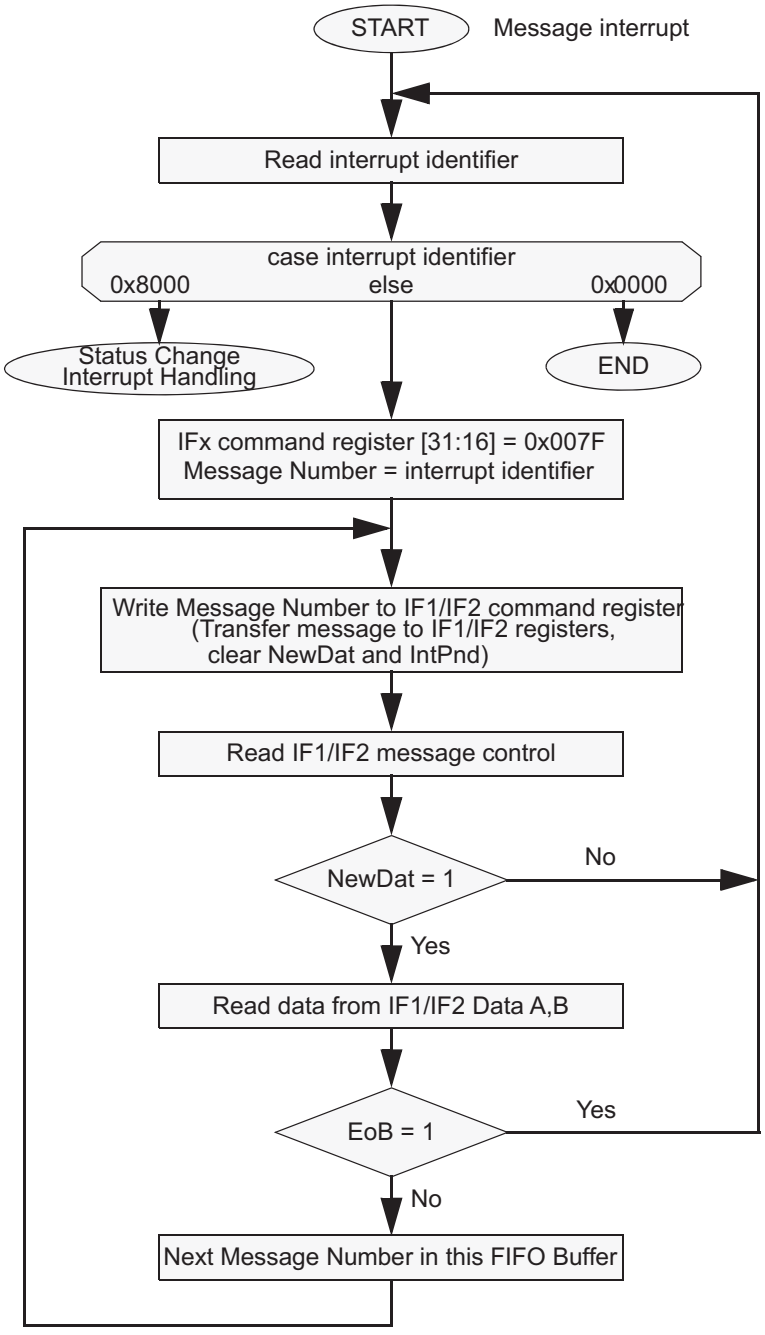
When a message is stored into a message object of a FIFO Buffer the NewDat bit of this message object is set. By setting NewDat while EoB is 0 the message object is locked for further write accesses by the Message Handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO Buffer until the last message object of this FIFO Buffer is reached. If none of the preceding message objects is released by writing NewDat to 0, all further messages for this FIFO Buffer will be written into the last message object of the FIFO Buffer (EoB = 1) and therefore overwrite previous messages in this message object.

27.8.12 Reading from a FIFO Buffer

Several messages may be accumulated in a set of message objects that are concatenated to form a FIFO Buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

A FIFO Buffer of length N will store N-1 plus the last received message since last time it was cleared.



A FIFO Buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 27-12.

NOTE: All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO Buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

27.9 CAN Message Transfer

Once the DCAN is initialized and Init bit is reset to zero, the CAN Core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The CPU may enable the interrupt lines (setting IE0 and IE1 to 1) at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication can be carried out in any of the following two modes:

1. Interrupt mode
2. Polling mode.

The Interrupt Register points to those message objects with IntPnd = 1. It is updated even if the interrupt lines to the CPU are disabled (IE0 / IE1 are zero).

The CPU may poll all Message Object's NewDat and TxRqst bits in parallel from the NewData X Registers and the Transmission Request X Registers. Polling can be made easier if all Transmit Objects are grouped at the low numbers, all Receive Objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence, when the identifier mask is used, the arbitration bits that are masked to "don't care" may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the Interface Registers, as the Message Handler guarantees data consistency in case of concurrent accesses (for reconfiguration, see Section 27.7.6)

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending (for reconfiguration, see Section 27.7.7). However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

27.9.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames that have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to you before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit DAR (Disable Automatic Retransmission) in CAN Control Register. Further details to this mode are provided in Section 27.8.3.

Copyright © 2018, Texas Instruments Incorporated

27.9.2 Auto-Bus-On

Per default, after the DCAN has entered Bus-Off state, the CPU can start a Bus-Off-Recovery sequence by resetting Init bit. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature that is enabled by bit ABO in CAN Control Register. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of VCLK cycles that can be defined in Auto-Bus-On Time Register.

NOTE: If the DCAN goes Bus-Off due to massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the Init bit. Once the Init bit has been reset by the CPU or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of Bus Idle (equal to 129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

27.10 Interrupt Functionality

Interrupts can be generated on two interrupt lines:

1. DCAN0INT line
2. DCAN1INT line

These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN Control Register.

The DCAN provides three groups of interrupt sources: Message Object Interrupts, Status Change Interrupts and Error Interrupts (see Figure 27-13 and Figure 27-14).

The source of an interrupt can be determined by the interrupt identifiers Int0ID / Int1ID in the Interrupt Register (see Section 27.17.5). When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the Interrupt Register DCAN INT (Int0ID / Int1ID) again reach zero (this means the cause of the interrupt is reset), or until IE0 / IE1 are reset.

The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN Core has updated (not necessarily changed) the Error and Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The CPU can update (reset) the status bits WakeUpPnd, RxOk, TxOk and LEC by reading the Error and Status Register DCAN ES, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, Int0ID resp. Int1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority, the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt, may read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1/IF2 Command Register). When IntPnd is cleared, the Interrupt Register will point to the next message object with a pending interrupt.

27.10.1 Message Object Interrupts

Message Object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE, that are described in Section 27.5.1.

Message Object interrupts can be routed to either DCAN0INT or DCAN1INT line, controlled by the Interrupt Multiplexer Register (see Section 27.17.22).

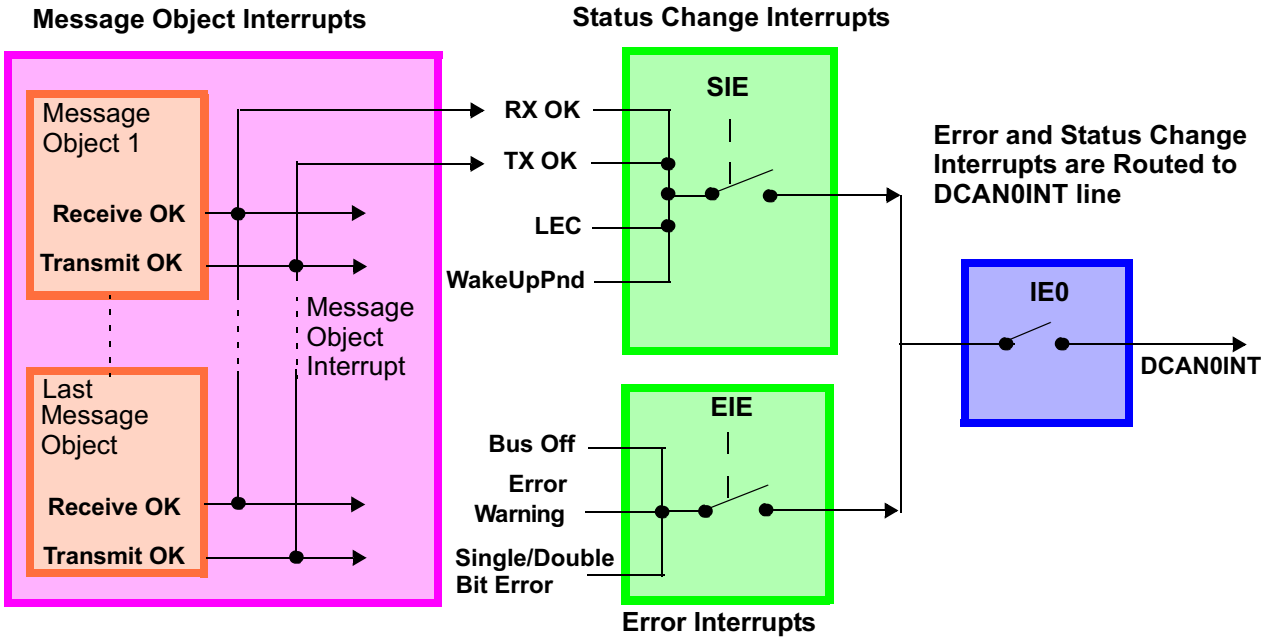
Copyright © 2018, Texas Instruments Incorporated

27.10.2 Status Change Interrupts

The events WakeUpPnd, RxOk, TxOk and LEC in Error and Status Register (DCAN ES) belong to the Status Change Interrupts. The Status Change Interrupt group can be enabled by bit in CAN Control Register.

If SIE is set, a Status Change Interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the Message RAM configuration.

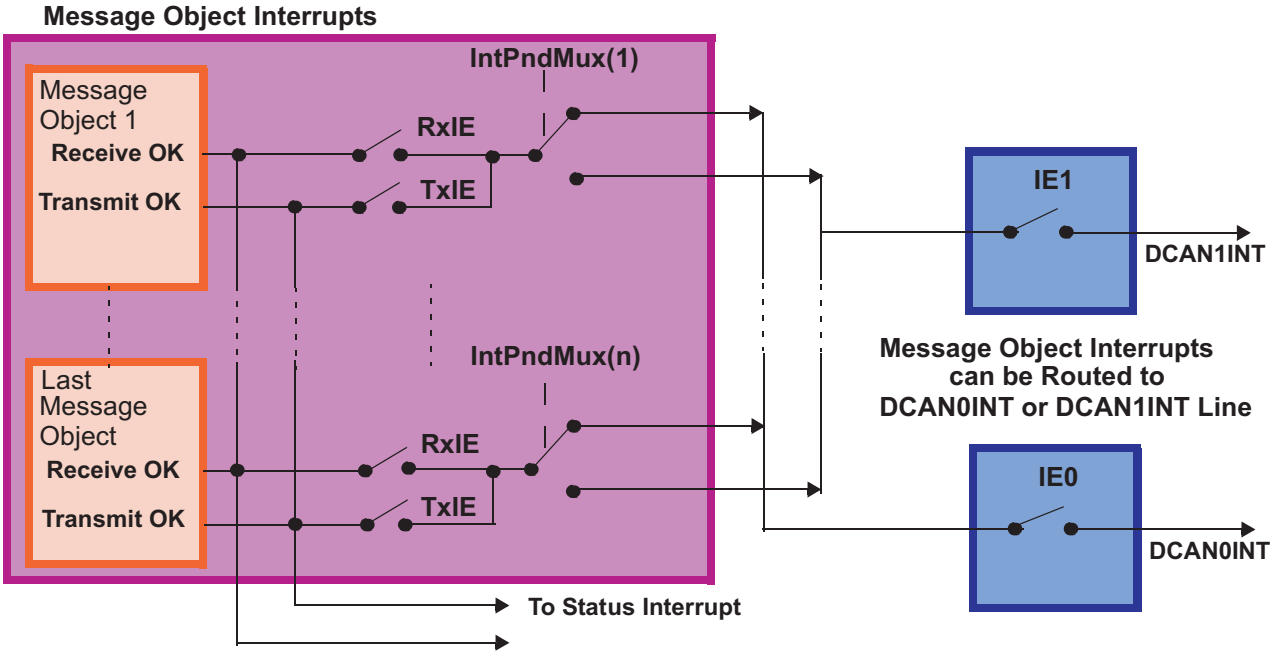
Status Change interrupts can only be routed to interrupt line DCAN0INT that has to be enabled by setting IE0 in the CAN Control Register.



NOTE: Reading the Error and Status Register will clear the WakeUpPnd flag. If in global power down mode, the WakeUpPnd flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WakeUpPnd flag, and a second interrupt may occur (additional information can be found in Section 27.11.2).

27.10.3 Error Interrupts

The events PER, BOff and EWarn (monitored in Error and Status Register, DCAN ES) belong to the Error Interrupts. The Error Interrupt group can be enabled by setting bit EIE in CAN Control Register.



Error interrupts can only be routed to interrupt line DCAN0INT that has to be enabled by setting IE0 in the CAN Control Register.

Figure 27-13. CAN Interrupt Topology 1

Copyright © 2018, Texas Instruments Incorporated

Figure 27-14. CAN Interrupt Topology 2

Details of Interrupt Mapping for actual device will be described in the device specific data sheet.

27.11 Global Power Down Mode

The device architecture supports a centralized global power down control over the peripheral modules through the Peripheral Central Resource (PCR) module (Additional information can be found in Platform Architecture Specification).

27.11.1 Entering Global Power Down Mode

The global power down mode for the DCAN is requested by setting the appropriate Peripheral Power Down Set bit (**PSPWRDWNSETx**) in the PCR module.

The DCAN then finishes all transmit requests of the message objects. When all requests are done, the DCAN waits until a bus idle state is recognized. Then it will automatically set the Initbit to indicate that the global power down mode has been entered.

27.11.2 Wakeup From Global Power Down Mode

When the DCAN module is in global power down mode, a CAN bus activity detection circuit exists, which can be active, if enabled. If this circuit is active,on occurrence of a dominant CAN bus level, the DCAN will set the **WakeUpPnd** bit in Error and Status Register (DCAN ES).

If Status Interrupts are enabled, also an interrupt will be generated. This interrupt could be used by the application to wakeup the DCAN. For this, the application needs to set the appropriate Peripheral Power Down Clear bit (**PSPWRDWNCLRx**) in the PCR module, and to clear the Init bit in CAN Control Register.

After the Init bit has been cleared, the DCAN module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes Bus-Active again.

NOTE: The CAN transceiver circuit has to stay active during CAN bus activity detection. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down mode is lost.

Copyright © 2018, Texas Instruments Incorporated

27.12 Local Power Down Mode

Besides the centralized power down mechanism controlled by the PCR module (global power down, see Section 27.15), the DCAN supports a local power down mode that can be controlled within the DCAN control registers.

27.12.1 Entering Local Power Down Mode

The local power down mode is requested by setting the PDR bit in CAN Control Register.

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the Initbit in CAN Control Register to prevent any further CAN transfers, and it will also set the PDA bit in CAN Error and Status Register. With setting the PDA bits, the DCAN module indicates that the local power down mode has been entered.

During local power down mode, the internal clocks of the DCAN module are turned off, but there is a wake up logic (see Section 27.12.2) that can be active, if enabled. Also the actual contents of the control registers can be read back.

NOTE: In local low power mode, the application should not clear the Init bit while PDR is set. If there are any messages in the Message RAM configured as to be transmitted and the application resets the init bit, these messages may be sent.

27.12.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power down mode:

1. The application could wake up the DCAN module manually by clearing the PDR bit and then clearing the Init bit in CAN Control Register.
2. Alternatively, a CAN bus activity detection circuit can be activated by setting the wake up on bus activity bit (WUBA) in CAN Control Register. If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wake up sequence. It will clear the PDR bit in CAN Control Register and also clear the PDA bit in Error and Status Register. The WakeUpPnd bit in CAN Error and Status Register will be set. If Status Interrupts are enabled, also an interrupt will be generated. Finally the Init bit in CAN control register will be cleared.

After the Init bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes Bus-Active again.

NOTE: The CAN transceiver circuit has to stay active while CAN bus observation. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, is lost.

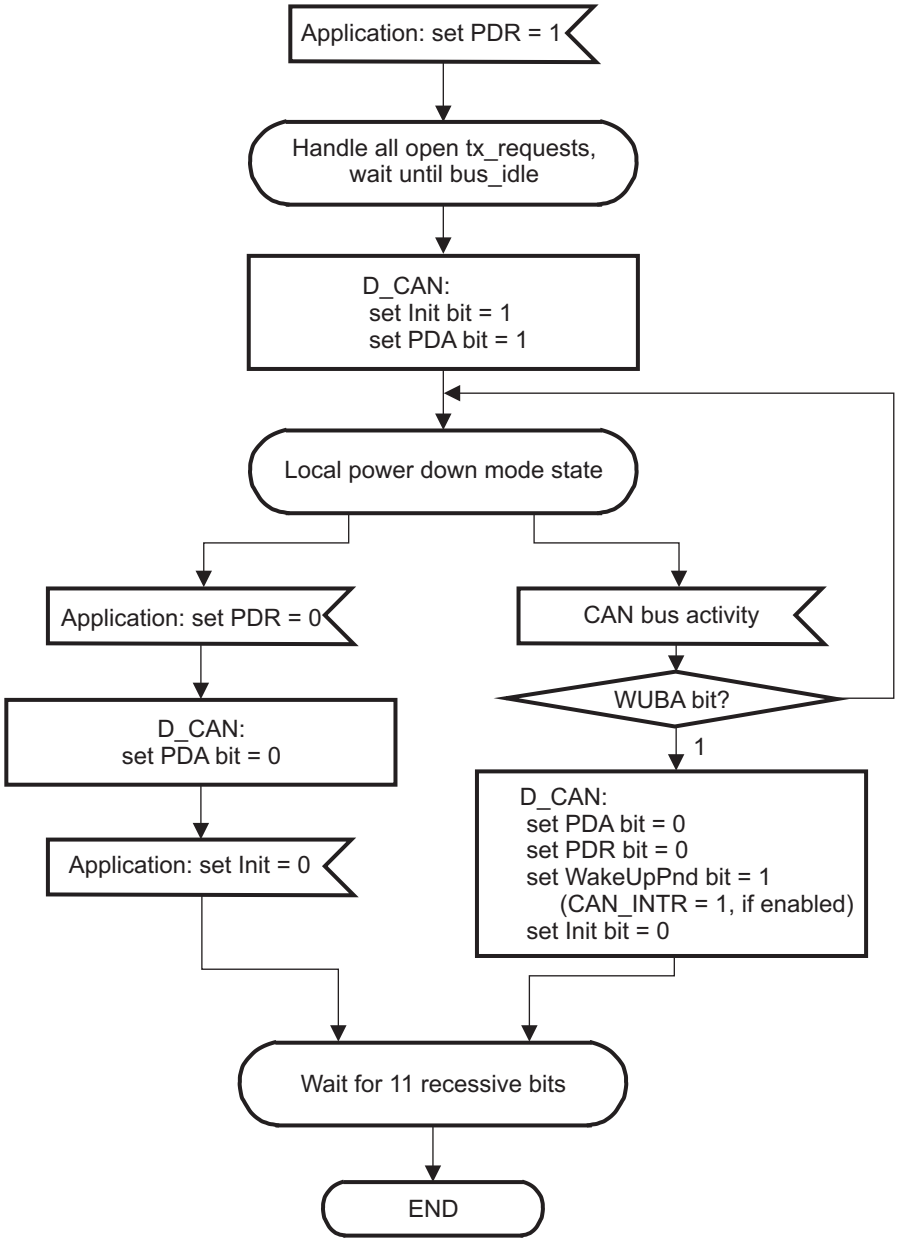


Figure 27-15 shows a flow diagram about entering and leaving local power down mode.

27.13 GIO Support

The CAN_RX and CAN_TX pins of each DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO Control register (see Section 27.17.34) and the CAN RX IO Control register (see Section 27.17.35).

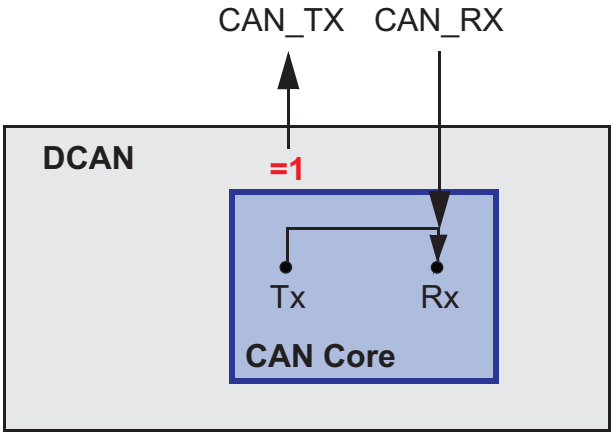
27.14 Test Modes

The DCAN provides several test modes that are mainly intended for production tests or self test.

For all test modes, Test bit in the CAN Control Register needs to be set to one. This enables write access to the Test Register.

NOTE: When using any of the Loop Back modes, it must be ensured by software that all message transfers are finished before setting the Init bit to '1'.

27.14.1 Silent Mode



The Silent Mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN Core.

Figure 27-16 shows the connection of signals CAN_TX and CAN_RX to the CAN Core in Silent Mode.

Silent Mode can be activated by setting the Silent bit in Test Register to 1.

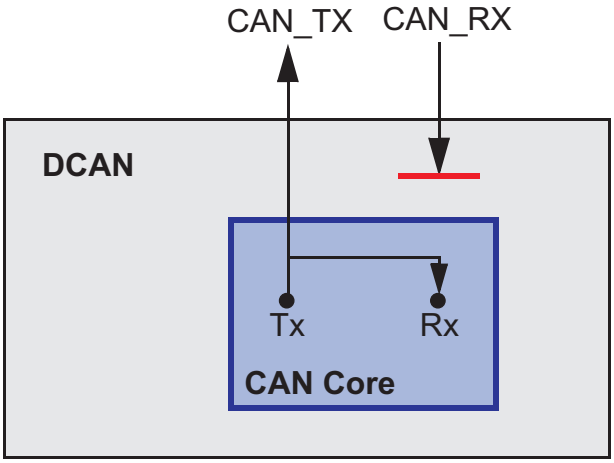
In ISO 11898-1, the Silent Mode is called the Bus Monitoring Mode.

Figure 27-16. CAN Core in Silent Mode

Copyright © 2018, Texas Instruments Incorporated

27.14.2 Loop Back Mode

The Loop Back Mode is mainly intended for hardware self-test functions. In this mode, the CAN Core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN Core. Transmitted messages still can be monitored at the CAN_TX pin.



In order to be independent from external stimulation, the CAN Core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back Mode.

Figure 27-17 shows the connection of signals CAN_TX and CAN_RX to the CAN Core in Loop Back Mode.

Loop Back Mode can be activated by setting bit LBack in Test Register to 1.

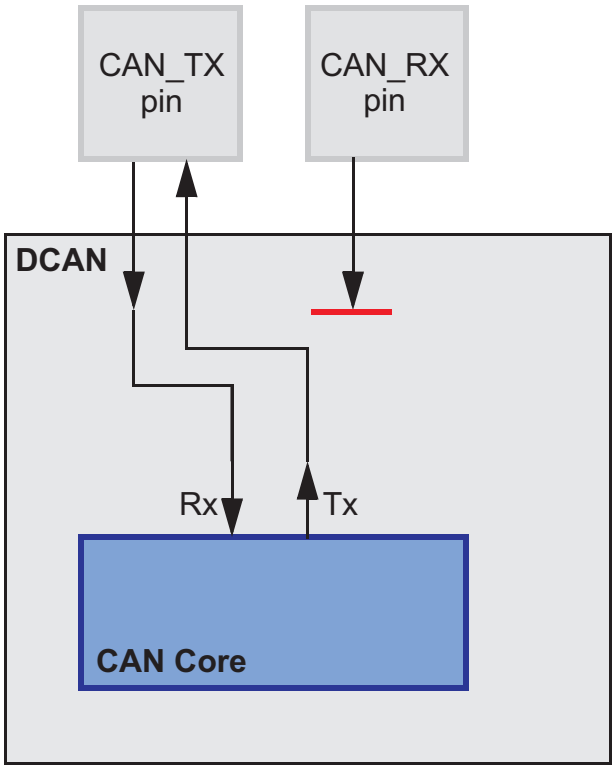
NOTE: In Loop Back mode, the signal path from CAN Core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN Core are disregarded. For including these into the testing, see External Loop Back mode (Section 27.14.3).

Figure 27-17. CAN Core in Loop Back Mode

Copyright © 2018, Texas Instruments Incorporated

27.14.3 External Loop Back Mode

The External Loop Back Mode is similar to the Loop Back Mode, however it includes the signal path from CAN Core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN Core. When External Loop Back Mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.



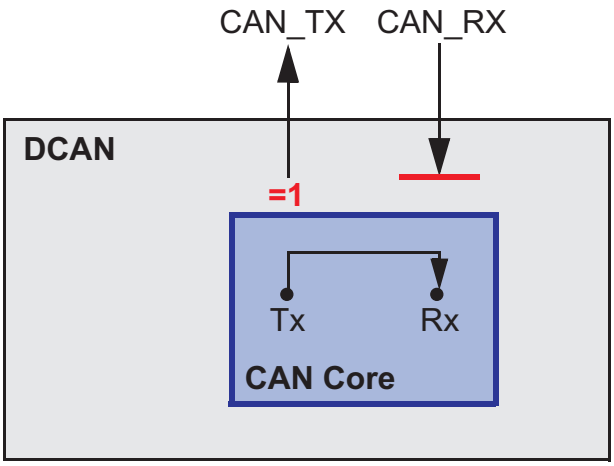
With this configuration, the Tx pin IO circuit can be tested.

External Loop Back Mode can be activated by setting bit ExL in Test Register to 1.

Figure 27-18 shows the connection of signals CAN_TX and CAN_RX to the CAN Core in External Loop Back Mode.

NOTE: When Loop Back Mode is active (LBack bit set), the ExL bit will be ignored.

Figure 27-18. CAN Core in External Loop Back Mode



Copyright © 2018, Texas Instruments Incorporated

27.14.4 Loop Back Combined with Silent Mode

It is also possible to combine Loop Back Mode and Silent Mode by setting bits LBack and Silent at the same time. This mode can be used for a “Hot Selftest”, that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN Core and no dominant bits will be sent on the CAN_TX pin.

Figure 27-19 shows the connection of the signals CAN_TX and CAN_RX to the CAN Core in case of the combination of Loop Back Mode with Silent Mode.

Figure 27-19. CAN Core in Loop Back Combined with Silent Mode

27.14.5 Software Control of CAN_TX Pin

Four output functions are available for the CAN transmit pin CAN_TX. Additionally to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN Sample Point signal to monitor the CAN Core’s bit timing.

Combined with the readable value of the CAN_RX pin, this can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the Test Register bits Tx[1:0] as described in Section 27.17.6.

NOTE: The software control for pin CAN_TX interferes with CAN protocol functions. For CAN message transfer or any of the test modes Loop Back Mode, External Loop Back Mode or Silent Mode, the CAN_TX pin should operate in its default functionality.

Copyright © 2018, Texas Instruments Incorporated

27.15 SECDED Mechanism

The DCAN module provides a single-bit error correction and double-bit error detection (SECDED) mechanism to ensure data integrity of Message RAM data. For each message object (136 bits) in the Message RAM, 9 ECC bits will be calculated. See Section 27.5.5.

The ECC bits are stored in a dedicated RAM. They will be generated on write accesses and will be checked on read accesses.

The SECDED functionality can be enabled or disabled by PMD bit field in CAN Control Register. If SECDED is enabled, ECC bits will be automatically generated and checked.

With the ECCMODE field in the ECC Control and Status register the single-bit error correction can be enabled or disabled (default: enabled).

NOTE: During RAM initialization, no ECC check will be done, but if the PMD bit is set, the ECC bits will be generated.

27.15.1 Behavior on Single-Bit Error

If a single-bit error is detected with single-bit error correction enabled, the correction will be done and the SEFLG in the ECC Control and Status register will be set.

If single-bit error correction is disabled and a single-bit error is detected then the SEFLG in the ECC Control and Status register and the the PER bit in the Error and Status register will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

The message object number where the single-bit error has occurred will be indicated in the ECC single-bit Error Code Register.

When single-bit error correction is disabled the message object data can be read by the host CPU, independently of single-bit errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the ECC single-bit Error Code Register on single-bit error interrupt.

27.15.2 Behavior on Double-Bit Error

If a double-bit error is detected, then the DEFLG in the ECC Control and Status register and the PER bit in Error and Status Register will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset. The message object number will be indicated in the Parity Error Code Register.

The message object data can be read by the host CPU, independently of double-bit errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the Parity Error Code register on double-bit error interrupt.

27.15.3 SECDED Testing

Testing of the SECDED mechanism can be implemented by using the diagnostic mode, which is enabled with the ECCDIAG register. The following procedure can be used:

1. Disable SECDED using DCAN control register. Enable diagnostic mode using the ECCDIAG register

2. Write to corrupt the data (in RDA mode) or ECC bits.

3. Enable SECDED and read data for which ECC is corrupted (either in RDA mode or via IFx registers).

4. single-bit error or double-bit error flag will be set in the diagnostic status register (ECCDIAG STAT) and in the ECC Control and Status register accordingly. A double-bit error or a single-bit error with single-bit error correction disabled also triggers the PER flag.

5. Disable diagnostic mode.

Copyright © 2018, Texas Instruments Incorporated

27.16 Debug/Suspend Mode

When the CPU is halted during debug, all DCAN registers are visible and can be inspected and modified by the CPU.

In addition, the Message RAM is directly memory-mapped as described in Table 27-3.

The CAN controller provides two options for entering the debug/suspend state. The options are controlled by the IDS bit in the CAN Control Register (DCAN CTL). By default, when IDS is 0, the DCAN controller completes any active transfers on the CAN bus and waits until the bus is idle before halting. When IDS is 1, the DCAN halts immediately as soon as the CPU is halted.

The InitDbg bit in DCAN CTL register indicates when the DCAN controller has actually entered the debug/suspend state.

NOTE: During Debug/Suspend Mode, the Message RAM cannot be accessed via the IFx register sets.

Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- Error and Status Register (clear of status flags by read)
- IF1/IF2 Command Registers (clear of DMAActive flag by read/write)

27.17 DCAN Control Registers

Table 27-6 lists the control registers of the DCAN. After hardware reset, the registers of the DCAN hold the values shown in the register descriptions. The base address for the control registers is FFF7 DC00h for DCAN1, FFF7 DE00h for DCAN2, FFF7 E000h for DCAN3, and FFF7 E200h for DCAN4.

Additionally, the Bus-Off state is reset and the CAN_TX pin is set to recessive (HIGH). The Init bit in the CAN Control Register is set to enable the software initialization. The DCAN will not influence the CAN bus until the CPU resets Init to 0.

27.17.1 CAN Control Register (DCAN CTL)

NOTE: The Bus-Off recovery sequence (see CAN specification) cannot be shortened by setting or resetting Init bit. If the module goes Bus-Off, it will automatically set the Init bit and stop all bus activities.

When the Init bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to the Error and Status Register, enabling the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the Bus-Off recovery sequence.

Table 27-7. CAN Control Register (DCAN CTL) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	These bits are always read as 0. Writes have no effect.
25	WUBA		Automatic wake up on bus activity when in local power down mode.
		0	No detection of a dominant CAN bus level while in local power down mode.
		1	Detection of a dominant CAN bus level while in local power down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started. (Additional information can be found in Section 27.12.)
			Note: The CAN message, which Initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost.
24	PDR		Request for local low power down mode.
		0	No application request for local low power down mode. If the application has cleared this bit while DCAN in local power down mode, also the Init bit has to be cleared.
		1	Local power down mode has been requested by application. The DCAN will acknowledge the local power down mode by setting bit PDA in Error and Status Register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in Section 27.12).
23-21	Reserved	0	These bits are always read as 0. Writes have no effect.
20	DE3		Enable DMA request line for IF3.
		0	Disabled
		1	Enabled
			Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers.

Table 27-7. CAN Control Register (DCAN CTL) Field Descriptions (continued)

Bit	Field	Value	Description
19	DE2		Enable DMA request line for IF2.
		0	Disabled
		1	Enabled
			Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers.
18	DE1		Enable DMA request line for IF1.
		0	Disabled
		1	Enabled
			Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers.
17	IE1		Interrupt line 1 enable.
		0	Disabled. Module Interrupt DCAN1INT is always low.
		1	Enabled. Interrupts will assert line DCAN1INT to one; line remains active until pending interrupts are processed.
16	InitDbg		Internal Init state while debug access.
		0	Not in debug mode, or debug mode requested but is not entered.
		1	Debug mode requested and is internally entered; the DCAN is ready for debug accesses.
15	SWR		SW reset enable.
		0	Normal operation.
		1	Module is forced to reset state. This bit will automatically get cleared after execution of SW reset after one VBUSP clock cycle.
			Note: To execute SW reset the following procedure is necessary: 1. Set Init bit to shut down CAN communication. 2. Set SWR bit additionally to Init bit.
14	Reserved	0	This bit is always read as 0. Writes have no effect.
13-10	PMD		SECDED enable.
		5h	SECDED function is disabled.
		All other values	SECDED function is enabled.
9	ABO		Auto-Bus-On enable.
		0	The Auto-Bus-On feature is disabled.
		1	The Auto-Bus-On feature is enabled.
8	IDS		Interruption debug support enable.
		0	When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode.
		1	When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.
7	Test		Test mode enable.
		0	Normal operation.
		1	Test mode.
6	CCE		Configuration change enable.
		0	The CPU has no write access to the BTR Config register.
		1	The CPU has write access to the BTR configuration register (when Init bit is set).
5	DAR		Disable automatic retransmission.
		0	Automatic Retransmission of not successful messages is enabled.
		1	Automatic Retransmission is disabled.
4	Reserved	0	This bit is always read as 0. Writes have no effect.

27.17.2 Error and Status Register (DCAN ES)

Interrupts are generated by bits PER, BOff, and EWarn (if EIE bit in CAN Control Register is set) and by bits WakeUpPnd, RxOk, TxOk, and LEC (if SIE bit in CAN Control Register is set). A change of bit EPass will not generate an Interrupt.

NOTE: Reading the Error and Status Register clears the WakeUpPnd, PER, RxOk and TxOk bits and set the LEC to value of 7. Additionally, the Status Interrupt value (8000h) in the Interrupt Register will be replaced by the next lower priority interrupt value.

For debug support, the auto clear functionality of Error and Status Register (clear of status flags by read) is disabled when in Debug/Suspend mode.

Figure 27-21. Error and Status Register (DCAN ES) [offset = 04h]

Table 27-8. Error and Status Register (DCAN ES) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	These bits are always read as 0. Writes have no effect.
10	PDA		Local power down mode acknowledge.
		0	DCAN is not in local power down mode.
		1	Application request for setting DCAN to local power down mode was successful. DCAN is in local power down mode.
9	WakeUp Pnd		Wake Up Pending.
			This bit can be used by the CPU to identify the DCAN as the source to wake up the system.
		0	No Wake Up is requested by DCAN.
		1	DCAN has initiated a wake up of the system due to dominant CAN bus while module power down. This bit will be reset if Error and Status Register is read.
8	PER		Single-/Double-bit error detected. This bit is set on double-bit errors and additionally on single-bit errors, if single-bit error correction is disabled with the ECCMODE bitfield in the ECC Control and Status register.
		0	No single-/double-bit error has been detected since last read access.
		1	The SECDED mechanism has detected a single-/double-bit error in the Message RAM. This bit will be reset if Error and Status Register is read.
7	BOff		Bus-Off State
		0	The CAN module is not Bus-Off state.
		1	The CAN module is in Bus-Off state.
6	EWarn		Warning State
		0	Both error counters are below the error warning limit of 96.
		1	At least one of the error counters has reached the error warning limit of 96.
5	EPass		Error Passive State
		0	On CAN Bus error, the DCAN could send active error frames.
		1	The CAN Core is in the error passive state as defined in the CAN Specification.

Copyright © 2018, Texas Instruments Incorporated

Table 27-8. Error and Status Register (DCAN ES) Field Descriptions (continued)

Bit	Field	Value	Description
4	RxOK		Received a message successfully.
		0	No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events.
		1	A message has been successfully received since the last time when this bit was reset by a read access of the CPU (independent of the result of acceptance filtering).This bit will be reset if Error and Status Register is read.
3	TxOK		Transmitted a message successfully.
		0	No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events.
		1	A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the CPU. This bit will be reset if Error and Status Register is read.
2-0	LEC		Last Error Code
			The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to 0 when a message has been transferred (reception or transmission) without error.
		0	No Error
		1h	Stuff Error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.
		2h	Form Error: A fixed format part of a received frame has the wrong format.
		3h	Ack Error: The message this CAN Core transmitted was not acknowledged by another node.
		4h	Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant.
		5h	Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value 0), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).
		6h	CRC Error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).
		7h	No CAN bus event was detected since the last time when CPU has read the Error and Status Register. Any read access to the Error and Status Register reinitializes the LEC bit to 7.

27.17.4 Bit Timing Register (DCAN BTR)

NOTE: This register is only writable if CCE and Init bits in the CAN Control Register are set.

The CAN bit time may be programmed in the range of 8 to 25 time quanta.

The CAN time quantum may be programmed in the range of 1 to 1024 CAN_CLK periods.

With a CAN_CLK of 8 MHz and BRPE = 00, the reset value of 2301h configures the DCAN for a bit rate of 500kBit/s.

For details see Section 27.3.2.1.

Figure 27-23. Bit Timing Register (DCAN BTR) [offset = 0Ch]

R-0	R/WP-2h		R/WP-3h		R/WP-0		R/WP-1h	

LEGEND: R/W = Read/Write; R = Read only; WP = Write Protected by CCE bit; *-n* = value after reset

Table 27-10. Bit Timing Register (DCAN BTR) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	These bits are always read as 0. Writes have no effect.
	BRPE	0-Fh	Baud Rate Prescaler Extension. Valid programmed values are 0 to 15. By programming BRPE the Baud Rate Prescaler can be extended to values up to 1024.
15	Reserved	0	This bit is always read as 0. Writes have no effect.
14-12	TSeg2	0-7h	Time segment after the sample point. Valid programmed values are 0 to 7. The actual TSeg2 value that is interpreted for the Bit Timing will be the programmed TSeg2 value + 1.
11-8	TSeg1	1h-Fh	Time segment before the sample point. Valid programmed values are 1 to 15. The actual TSeg1 value interpreted for the Bit Timing will be the programmed TSeg1 value + 1.
7-6	SJW	0-3h	Synchronization Jump Width Valid programmed values are 0 to 3. The actual SJW value interpreted for the Synchronization will be the programmed SJW value + 1.
5-0	BRP	0-3Fh	Baud Rate Prescaler Value by which the CAN_CLK frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid programmed values are 0 to 63. The actual BRP value interpreted for the Bit Timing will be the programmed BRP value + 1.

31	24	23	16
Reserved		Int1ID	
R-0		R-0	

15	0
Int0ID	
R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 27-11. Interrupt Register (DCAN INT) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	These bits are always read as 0. Writes have no effect.
23-16	Int1ID		Interrupt 1 Identifier (indicates the message object with the highest pending interrupt).
		0	No interrupt is pending.
		1h-40h	Number of message object that caused the interrupt.
		41h-FFh	Unused
			If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority. The DCAN1INT interrupt line remains active until Int1ID reaches value 0 (the cause of the interrupt is reset) or until IE1 is cleared.
			A message interrupt is cleared by clearing the message object's IntPnd bit.
			Among the message interrupts, the message object's interrupt priority decreases with increasing message number.
15-0	Int0ID		Interrupt Identifier (indicates the source of the interrupt).
		0	No interrupt is pending.
		1h-40h	Number of message object that caused the interrupt.
		41h-7FFFh	Unused
		8000h	Error and Status Register value is not 7h.
		8001h-FFFFh	Unused
			If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority. The DCAN0INT interrupt line remains active until Int0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared.
			The Status Interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number.

27.17.6 Test Register (DCAN TEST)

For all test modes, the Test bit in CAN Control Register needs to be set to one. If Test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of pin CAN_RX and therefore is only readable. All Test Register functions are disabled when Test bit is cleared.

NOTE: The Test Register is only writable if Test bit in CAN Control Register is set.

Setting Tx[1:0] other than 00 will disturb message transfer.

When the internal loop back mode is active (bit LBack is set), bit EXL will be ignored.

Figure 27-25. Test Register (DCAN TEST) [offset = 14h]

27.17.7 Parity Error Code Register (DCAN PERR)

If a double-bit error is detected, the PER flag will be set in the Error and Status Register. This bit is not reset by the SECDED mechanism; it must be reset by reading the Error and Status Register. In addition to the PER flag, the SECDED Error Code Register will indicate the memory area where the double-bit error has been detected (message number). After a double-bit error has been detected, the register will hold the last error code until power is removed.

27.17.12 ECC Single-Bit Error Code Register (DCAN ECC SERR)

If an ECC single-bit error is detected, the SEFLG flag is set in the ECC Control and Status Register. In addition to the SEFLG flag, the ECC Single-Bit Error Code Register indicates the memory area where the single-bit error has been detected (message object number only).

If more than one word with an ECC single-bit error is detected, the highest word number with an ECC single-bit error is displayed.

After an ECC single-bit error is detected, the register holds the last error code until power is removed.

ABO_TIME	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 27-19. Auto-Bus-On Time Register (DCAN ABOTR) Field Descriptions

Bit	Field	Description
31-0	ABO_TIME	Number of VBUS clock cycles before a Bus-Off recovery sequence is started by clearing the Init bit. This function has to be enabled by setting bit ABO in CAN Control Register. The Auto-Bus-On timer is realized by a 32-bit counter that starts to count down to 0 when the module goes Bus-Off. The counter will be reloaded with the preload value of the ABO_TIME register after this phase.

27.17.14 Transmission Request X Register (DCAN TXRQ X)

With the Transmission Request X Register, the CPU can detect if one or more bits in the different Transmission Request Registers are set. Each register bit represents a group of eight message objects. If at least one of the TxRqst bits of these message objects are set, the corresponding bit in the Transmission Request X Register will be set.

27.17.20 Message Valid X Register (DCAN MSGVAL X)

With the Message Valid X Register, the CPU can detect if one or more bits in the different Message Valid Registers are set. Each bit of this register represents a group of eight message objects. If at least one of the MsgVal bits of these message objects are set, the corresponding bit in the Message Valid X Register will be set.

27.17.21 Message Valid Registers (DCAN MSGVAL12 to DCAN MSGVAL78)

These registers hold the MsgVal bits of the implemented message objects. By reading out these bits, the CPU can check which message objects are valid. The MsgVal bit of a specific message object can be set/reset by the CPU via the IF1/IF2 Interface Register sets, or by the Message Handler after a reception or a successful transmission.

27.17.22 Interrupt Multiplexer Registers (DCAN INTMUX12 to DCAN INTMUX78)

The IntMux flag determines for each message object which of the two interrupt lines (DCAN0INT or DCAN1INT) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN Control Register.

The IntPnd bit of a specific message object can be set or reset by the CPU via the IF1/IF2 Interface Register sets, or by Message Handler after reception or successful transmission of a frame. This will also affect the Int0ID resp Int1ID flags in the Interrupt Register.

27.17.23 IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD)

The IF1/IF2 Command Register configure and Initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred.

A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to 1 to indicate that a transfer is in progress.

After 4 to 14 VBUS clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.

NOTE: While Busy bit is one, IF1/IF2 Register sets are write protected.

For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAactive flag by r/w) is disabled during Debug/Suspend mode.

If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

Table 27-25. IF1/IF2 Command Register Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	These bits are always read as 0. Writes have no effect.
23	WR/RD		Write/Read
		0	Direction = Read: Transfer direction is from the message object addressed by Message Number (Bits [7:0]) to the IF1/IF2 register set.
		1	Direction = Write: Transfer direction is from the IF1/IF2 register set to the message object addressed by Message Number (Bits [7:0]).
22	Mask		Access Mask bits.
		0	Mask bits will not be changed.
		1	Direction = Read: The Mask bits (Identifier Mask + MDir + MXtd) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the IF1/IF2 Register set. Direction = Write: The Mask bits (Identifier Mask + MDir + MXtd) will be transferred from the IF1/IF2 Register set to the message object addressed by Message Number (Bits [7:0]).
21	Arb		Access Arbitration bits.
		0	Arbitration bits will not be changed.
		1	Direction = Read: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1/IF2 Register set. Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF1/IF2 Register set to the message object addressed by Message Number (Bits [7:0]).
20	Control		Access Control bits.
		0	Control bits will not be changed.
		1	Direction = Read: The Message Control bits will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1/IF2 Register set. Direction = Write: The Message Control bits will be transferred from the IF1/IF2 Register set to the message object addressed by Message Number (Bits [7:0]). If the TxRqst/NewDat bit in this register (Bit [18]) is set, the TxRqst/NewDat bit in the IF1/IF2 Message Control Register will be ignored.
19	ClrIntPnd		Clear Interrupt Pending bit.
		0	IntPnd bit will not be changed.
		1	Direction = Read: Clears IntPnd bit in the message object. Direction = Write: This bit is ignored. Copying of IntPnd flag from IF1/IF2 Registers to Message RAM can be controlled by only the Control flag (Bit [20]).
18	TxRqst/NewDat		Access Transmission Request bit.
		0	Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the Control bit.
		1	Direction = Read: Clears NewDat bit in the message object. Direction = Write: Sets TxRqst/NewDat in the message object. **Note:** If a CAN transmission is requested by setting TxRqst/NewDat in this register, the TxRqst/NewDat bits in the message object will be set to 1 and independent of the values in IF1/IF2 Message Control Register. A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the IF1/IF2 Message Control Register always reflect the status before resetting them.
17	Data A		Access Data Bytes 0–3.
		0	Data Bytes 0–3 will not be changed.
		1	Direction = Read: The Data Bytes 0–3 will be transferred from the message object addressed by the Message Number (Bits [7:0]) to the corresponding IF1/IF2 Register set. Direction = Write: The Data Bytes 0–3 will be transferred from the IF1/IF2 Register set to the message object addressed by the Message Number (Bits [7:0]). **Note:** The duration of the message transfer is independent of the number of bytes to be transferred.

Copyright © 2018, Texas Instruments Incorporated

Table 27-25. IF1/IF2 Command Register Field Descriptions (continued)

Bit	Field	Value	Description
16	Data B		Access Data Bytes 4–7.
		0	Data Bytes 4–7 will not be changed.
		1	Direction = Read: The Data Bytes 4–7 will be transferred from the message object addressed by the Message Number (Bits [7:0]) to the corresponding IF1/IF2 Register set.
			Direction = Write: The Data Bytes 4–7 will be transferred from the IF1/IF2 Register set to the message object addressed by the Message Number (Bits [7:0]).
			Note: The duration of the message transfer is independent of the number of bytes to be transferred.
15	Busy		Busy flag.
		0	No transfer between IF1/IF2 Register set and Message RAM is in progress.
		1	Transfer between IF1/IF2 Register set and Message RAM is in progress. This bit is set to 1 after the message number has been written to bits [7:0]. IF1/IF2 Register set will be write-protected. The bit is cleared after read/write action has finished.
14	DMA Active		Activation of DMA feature for subsequent internal IF1/IF2 update.
		0	DMA request line is independent of IF1/IF2 activities.
		1	DMA is requested after completed transfer between IF1/IF2 Register set and Message RAM. The DMA request remains active until the first read or write to one of the IF1/IF2 registers. An exception is a write to Message Number (Bits [7:0]) when DMA Active is 1.
			Note: Due to the auto reset feature of the DMA Active bit, this bit has to be separately set for each subsequent DMA cycle.
13-8	Reserved	0	These bits are always read as 0. Writes have no effect.
7-0	Message Number		Number of message object in Message RAM that is used for data transfer.
		0	Invalid message number.
		1h-40h	Valid message numbers.
		41h-FFh	Invalid message numbers.
			Note: When an invalid message number is written to the IF1/IF2 Command Register that is higher than the last implemented message object number, a modulo addressing will occur. For example, when accessing message object 33 in a DCAN module with 32 message objects only, the message object 1 will be accessed instead.

Copyright © 2018, Texas Instruments Incorporated

27.17.24 IF1/IF2 Mask Registers (DCAN IF1MSK, DCAN IF2MSK)

The bits of the IF1/IF2 Mask Registers mirror the mask bits of a message object. The function of the relevant message objects bits is described in Section 27.5.1.

NOTE: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write protected.

Figure 27-59. IF1 Mask Register (DCAN IF1MSK) [offset = 104h]

Table 27-26. IF1/IF2 Mask Register Field Descriptions

Bit	Field	Value	Description
31	MXtd		Mask extended identifier.
		0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
		1	The extended identifier bit (IDE) is used for acceptance filtering.
			When 11-bit ("standard") identifiers are used for a message object, the identifiers of received Data Frames are written into bits ID[28:18]. For acceptance filtering, only these bits with mask bits Msk[28:18] are considered.
30	MDir		Mask message direction.
		0	The message direction bit (Dir) has no effect on the acceptance filtering.
		1	The message direction bit (Dir) is used for acceptance filtering.
29	Reserved	0	These bits are always read as 1. Writes have no effect.
28-0	Msk[*n*]		Identifier mask.
		0	The corresponding bit in the identifier of the message object is not used for acceptance filtering (don't care).
		1	The corresponding bit in the identifier of the message object is used for acceptance filtering.

Copyright © 2018, Texas Instruments Incorporated

27.17.25 IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB)

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in Section 27.5.1.

The Arbitration bits ID, Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk, MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = 1, standard frames in message objects with Xtd = 0.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

NOTE: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write protected.

Table 27-27. IF1/IF2 Arbitration Register Field Descriptions

Bit	Field	Value	Description
31	MsgVal		Message valid
		0	The message object is ignored by the Message Handler.
		1	The message object is used by the Message Handler.
			Note: The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit Init in the CAN Control Register. MsgVal must also be reset if the messages object is no longer used in operation. For reconfiguration of message objects during normal operation, see Section 27.7.6 and Section 27.7.7.
30	Xtd		Extended identifier.
		0	The 11-bit ("standard") identifier is used for this message object.
		1	The 29-bit ("extended") identifier is used for this message object.
29	Dir		Message direction.
		0	Direction = Receive: On TxRqst, a Remote Frame with the identifier of this message object is transmitted. On receiving a Data Frame with a matching identifier, this message is stored in this message object.
		1	Direction = Transmit: On TxRqst, the respective message object is transmitted as a Data Frame. On receiving a Remote Frame with a matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).
28-0	ID		Message identifier.
		ID[28:0]	29-bit Identifier ("Extended Frame").
		ID[28:18]	11-bit Identifier ("Standard Frame").

Table 27-28. IF1/IF2 Message Control Register Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	These bits are always read as 0. Writes have no effect.
15	NewDat		New Data
		0	No new data has been written into the data portion of this message object by the Message Handler since the last time this flag was cleared by the CPU.
		1	The Message Handler or the CPU has written new data into the data portion of this message object.
14	MsgLst		Message Lost (only valid for message objects with direction = receive).
		0	No message lost since the last time when this bit was reset by the CPU.
		1	The Message Handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten.
13	IntPnd		Interrupt Pending
		0	This message object is not the source of an interrupt.
		1	This message object is the source of an interrupt. The interrupt identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority.
12	UMask		Use Acceptance Mask
		0	Mask is ignored.
		1	Use Mask (Msk[28:0], MXtd, and MDir) for acceptance filtering.
			If the UMask bit is set to 1, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to 1.
11	TxIE		Transmit interrupt enable.
		0	IntPnd will not be triggered after the successful transmission of a frame.
		1	IntPnd will be triggered after the successful transmission of a frame.
10	RxIE		Receive interrupt enable.
		0	IntPnd will not be triggered after the successful reception of a frame.
		1	IntPnd will be triggered after the successful reception of a frame.
9	RmtEn		Remote enable.
		0	At the reception of a Remote Frame, TxRqst is not changed.
		1	At the reception of a Remote Frame, TxRqst is set.
8	TxRqst		Transmit request.
		0	This message object is not waiting for a transmission.
		1	The transmission of this message object is requested and not yet done.
7	EoB		End of Block
		0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
		1	The message object is a single message object or the last message object in a FIFO Buffer block.
			Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to 1.
6-4	Reserved	0	These bits are always read as 0. Writes have no effect.
3-0	DLC		Data Length Code
		0-8h	Data Frame has 0-8 data bits.
		9h-Fh	Data Frame has 8 data bytes.
			Note: The Data Length Code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.

Copyright © 2018, Texas Instruments Incorporated

27.17.27 IF1/IF2 Data A and Data B Registers (DCAN IF1DATA/DATB, DCAN IF2DATA/DATB)

The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order.

In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first

27.17.28 IF3 Observation Register (DCAN IF3OBS)

The IF3 register set can automatically be updated with received message objects without the need to Initiate the transfer from Message RAM by CPU (Additional information can be found in Section 27.5.1).

The observation flags (Bits [4:0]) in the IF3 Observation register are used to determine, which data sections of the IF3 Interface Register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 Interface Register set with new data.

Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

NOTE: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.

A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 Interface Register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register.

The status of the current read-cycle can be observed via status flags (Bits [12:8]).

An interrupt request may be generated by the IF3Upd flag if the DE3 bit of DCAN CTL register is set. See the device data sheet to find out if this interrupt source is available.

With this, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode.

Table 27-31. IF3 Arbitration Register (DCAN IF3ARB) Field Descriptions

Bit	Field	Value	Description
31	MsgVal		Message valid.
		0	The message object is ignored by the Message Handler.
		1	The message object is to be used by the Message Handler.
			Note: The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit Init in the CAN Control Register. MsgVal must also be reset if the messages object is no longer used in operation. For reconfiguration of message objects during normal operation, see Section 27.7.6 and Section 27.7.7.
30	Xtd		Extended identifier.
		0	The 11-bit ("standard") identifier is used for this message object.
		1	The 29-bit ("extended") identifier is used for this message object.
29	Dir		Message direction.
		0	Direction = Receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On receiving a data frame with a matching identifier, the message is stored in this message object.
		1	Direction = Transmit: On TxRqst, the respective message object is transmitted as a data frame. On receiving a remote frame with a matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).
28-0	ID		Message identifier.
		ID[28:0]	29-bit Identifier ("Extended Frame").
		ID[28:18]	11-bit Identifier ("Standard Frame").

LEGEND: R = Read; -*n* = value after reset

Table 27-32. IF3 Message Control Register (DCAN IF3MCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	These bits are always read as 0. Writes have no effect.
15	NewDat		New Data
		0	No new data has been written into the data portion of this message object by the Message Handler since the last time this flag was cleared by the CPU.
		1	The Message Handler or the CPU has written new data into the data portion of this message object.
14	MsgLst		Message Lost (only valid for message objects with direction = receive).
		0	No message lost since the last time when this bit was reset by the CPU.
		1	The Message Handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten.
13	IntPnd		Interrupt Pending.
		0	This message object is not the source of an interrupt.
		1	This message object is the source of an interrupt. The interrupt identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority.
12	UMask		Use Acceptance Mask.
		0	Mask is ignored.
		1	Use Mask (Msk[28:0], MXtd, and MDir) for acceptance filtering.
			If the UMask bit is set to 1, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to 1.
11	TxIE		Transmit interrupt enable.
		0	IntPnd will not be triggered after the successful transmission of a frame.
		1	IntPnd will be triggered after the successful transmission of a frame.
10	RxIE		Receive interrupt enable.
		0	IntPnd will not be triggered after the successful transmission of a frame.
		1	IntPnd will be triggered after the successful transmission of a frame.
9	RmtEn		Remote enable.
		0	At the reception of a Remote Frame, TxRqst is not changed.
		1	At the reception of a Remote Frame, TxRqst is set.
8	TxRqst		Transmit request.
		0	This message object is not waiting for a transmission.
		1	The transmission of this message object is requested and not yet done.

Table 27-32. IF3 Message Control Register (DCAN IF3MCTL) Field Descriptions (continued)

Bit	Field	Value	Description
7	EoB		End of Block
		0	The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block.
		1	The message object is a single message object or the last message object in a FIFO Buffer block.
			Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to 1.
6-4	Reserved	0	These bits are always read as 0. Writes have no effect.
3-0	DLC		Data Length Code
		0-8h	Data Frame has 0-8 data bits.
		9h-Fh	Data Frame has 8 data bytes.
			Note: The Data Length Code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.

27.17.32 IF3 Data A and Data B Registers (DCAN IF3DATA/DATB)

The data bytes of CAN messages are stored in the IF3 registers in the following order.

In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

27.17.33 IF3 Update Enable Registers (DCAN IF3UPD12 to DCAN IF3UPD78)

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (for example, due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set.

NOTE: IF3 Update enable should not be set for transmit objects.

27.17.34 CAN TX IO Control Register (DCAN TIOC)

The CAN_TX pin of the DCAN module can be used as general-purpose IO pin if CAN function is not needed.

NOTE: The values of the IO Control registers are only writable if Init bit of CAN Control Register is set.

The OD, Func, Dir, and Out bits of the CAN TX IO Control register are forced to certain values when Init bit of CAN Control Register is reset (see bit descriptions).

Figure 27-79. CAN TX IO Control Register (DCAN TIOC) [offset = 1E0h]

31	19	18	17	16
Reserved		PU	PD	OD
R-0		R/W-D	R/W-D	R/WP-0

15	4	3	2	1	0
Reserved		Func	Dir	Out	In
R-0		R/WP-0	R/WP-0	R/WP-0	R-U

LEGEND: R/W = Read/Write; R = Read; WP = Protected Write (protected by Init bit); D = Device-dependent; -*n* = value after reset

Table 27-34. CAN TX IO Control Register (DCAN TIOC) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	These bits are always read as 0. Writes have no effect.
18	PU		CAN_TX Pullup/Pulldown select. This bit is only active when CAN_TX is configured to be an input.
		0	CAN_TX Pulldown is selected, when pull logic is active (PD = 0).
		1	CAN_TX Pullup is selected, when pull logic is active (PD = 0).
17	PD		CAN_TX pull disable. This bit is only active when CAN_TX is configured to be an input.
		0	CAN_TX pull is active.
		1	CAN_TX pull is disabled.
16	OD		CAN_TX open drain enable. This bit is only active when CAN_TX is configured to be in GIO mode (TIOC.Func = 0).
		0	The CAN_TX pin is configured in push/pull mode.
		1	The CAN_TX pin is configured in open drain mode.
			Forced to 0, if Init bit of CAN control register is reset.
15-4	Reserved	0	These bits are always read as 0. Writes have no effect.
3	Func		CAN_TX function. This bit changes the function of the CAN_TX pin.
		0	CAN_TX pin is in GIO mode.
		1	CAN_TX pin is in functional mode (as an output to transmit CAN data).
			Forced to 1, if Init bit of CAN control register is reset.
2	Dir		CAN_TX data direction. This bit controls the direction of the CAN_TX pin when it is configured to be in GIO mode only (TIOC.Func = 0).
		0	The CAN_TX pin is an input.
		1	The CAN_TX pin is an output.
			Forced to 1, if Init bit of CAN control register is reset.
1	Out		CAN_TX data out write. This bit is only active when CAN_TX pin is configured to be in GIO mode (TIOC.Func = 0) and configured to be an output pin (TIOC.Dir = 1). The value of this bit indicates the value to be output to the CAN_TX pin.
		0	The CAN_TX pin is driven to logic low (0).
		1	The CAN_TX pin is at logic high (1).
			Forced to Tx output of the CAN Core, if Init bit of CAN Control register is reset.

Copyright © 2018, Texas Instruments Incorporated

Table 27-34. CAN TX IO Control Register (DCAN TIOC) Field Descriptions (continued)

Bit	Field	Value	Description
0	In		CAN_TX data in.
		0	The CAN_TX pin is at logic low (0).
		1	The CAN_TX pin is at logic high (1).
			Note: When CAN_TX pin is connected to a CAN transceiver, an external pullup resistor has to be used to ensure that the CAN bus will not be disturbed (for example, while the DCAN module is reset).

27.17.35 CAN RX IO Control Register (DCAN RIOC)

The CAN_RX pin of the DCAN module can be used as general-purpose IO pin if CAN function is not needed.

NOTE: The values of the IO Control registers are writable only if Init bit of CAN Control Register is set.

The OD, Func, and Dir bits of the CAN RX IO Control register are forced to certain values when Init bit of CAN Control Register is reset, see bit description.

Figure 27-80. CAN RX IO Control Register (DCAN RIOC) [offset = 1E4h]

Multi-Buffered Serial Peripheral Interface Module (MibSPI) with Parallel Pin Option (MibSPIP)

This chapter provides the specifications for a 16-bit configurable synchronous multi-buffered multi-pin serial peripheral interface (MibSPI). This chapter also provides the specifications for MibSPI with Parallel Pin Option (MibSPIP). The MibSPI is a programmable-length shift register used for high-speed communication between external peripherals or other microcontrollers.

Throughout this chapter, all references to SPI also apply to MibSPI/MibSPIP, unless otherwise noted.

NOTE: This chapter describes a superset implementation of the MibSPI/SPI modules that includes features and functionality that may not be available on some devices. Device-specific content that should be determined by referencing the datasheet includes DMA functionality, MibSPI RAM size, number of transfer groups, number of chip selects, parallel mode support, and availability of 5-pin operation (SPInENA).

Topic **Page**

28.1 Overview **1498**
28.2 Basic Operation **1500**
28.3 Control Registers **1535**
28.4 Multi-buffer RAM **1605**
28.5 Parity\ECC Memory **1612**
28.6 MibSPI Pin Timing Parameters **1617**

Copyright © 2018, Texas Instruments Incorporated

28.1 Overview

28.1.1 Features

The MibSPI/SPI is a high-speed synchronous serial input/output port that allows a serial bit stream of programmed length (two to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The MibSPI/SPI is normally used for communication between the microcontroller and external peripherals or another microcontroller. Typical applications include interface to external I/O or peripheral expansion via devices such as shift registers, display drivers, and analog-to-digital converters. MibSPI is an Extension of SPI. MibSPI works in 2 modes.

- Compatibility Mode
- Multi-buffer Mode

The Compatibility mode of MibSPI makes it behave exactly like that of SPI and ensures full compatibility with the same. Everything described about compatibility mode of MibSPI , in this document, is directly applicable to SPI.

The Multi-buffer mode of operation is specific to MibSPI alone. This feature is not available in SPI.

The MibSPI supports memory fault detection/correction via internal Parity/ECC circuit. MibSPI is configurable to include or not include Memory Parity/ECC logic during circuit synthesis.

The SPI / MibSPI can be configured in three pin, four pin or five pin mode of operation. The SPI / MibSPI allows multiple programmable chip-selects.

The MibSPI has a programmable Multi-buffer array that enables programed transmission to be completed without CPU intervention. The buffers are combined in different transfer groups that could be triggered by external events (Timers, I/O, and so on) or by the internal tick counter. The internal tick counter can support periodic trigger events. Each buffer of the MibSPI can be associated with different DMA channels in different transfer group, allowing the user to move data from/to internal memory to/from external slave with a minimal CPU interaction.

The SPICLK, SPISIMO, and SPISOMI pins are used in all MibSPI pin modes. The $\overline{\text{SPIENA}}$ and $\overline{\text{SPICS}}$ pins are optional and may be used if the pin are present on a given device.

The SPI has the following attributes:

- 16-bit shift register
- Receive buffer register
- 8-bit baud clock generator
- Serial clock (SPICLK) I/O pin
- Up to 8 Slave out, Master in (SPISOMI) I/O pins for faster data transfers
- SPI enable ($\overline{\text{SPIENA}}$) pin (4 or 5-pin mode only)
- Up to 6 slave chip select ($\overline{\text{SPICS}}$) pins (4 or 5-pin mode only)
- SPI pins can be used as functional or digital Input/Output pins (GIOs)

The SPI/MibSPI allows software to program the following options:

- SPISOMI/SPISIMO pin direction configuration
- SPICLK pin source (external/internal)
- MibSPI pins as functional or digital I/O pins. For each Buffer, the following features can be selected from four different combinations of formats using the control fields in the buffer:
  - SPICLK frequency
  - Character length
  - Phase
  - Polarity
  - Enable/Disable parity for transmit and receive
  - Enable/Disable timers for Chip Select Hold and Setup timers
  - Direction of shifting, MSBit first or LSBit first

Copyright © 2018, Texas Instruments Incorporated

– Configurable Parallel modes to use multiple SIMO/SOMI pin
– Configurable number of Chip Selects

In Multi-buffer Mode, in addition to the previous features, many other features are configurable:

– Number of buffers for each peripheral (or data source/destination, up to 256 buffers supported) or group (up to 8 groupings)
– Number of DMA controlled buffers and number of DMA request channels (up to 8 for each of transmit and receive)
– Triggers for each groups, trigger types, trigger sources for individual groups(up to 14 external trigger sources and 1 internal trigger source)
– Number of DMA transfers for each buffer (up to 65536 for up to 8 buffers)
– Un-interrupted DMA buffer transfer (NOBREAK buffer)

NOTE: SIMO - Slave In Master Out Pin
SOMI - Slave Out Master In Pin
SPICS - SPI Chip Select Pin
SPIENA - SPI Enable Pin.

28.1.2 Pin Configurations

The SPI supports data connections as shown in Table 28-1.

Table 28-1. Pin Configurations

Pin	Master Mode		Slave Mode	
SPICLK	Drives the clock to external devices		Receives the clock from the external master	
SPISOMI	Receives data from the external slave		Sends data to the external master	
SPISIMO	Transmits data to the external slave		Receives data from the external master	
$\overline{\text{SPIENA}}$	**SPIENA disabled:** GIO	**SPIENA enabled:** Receives ENA signal from the external slave	**SPIENA disabled:** GIO	**SPIENA enabled:** Drives ENA signal from the external master
$\overline{\text{SPICS}}$	**SPICS disabled:** GIO	**SPICS enabled:** Selects one or more slave devices	**SPICS disabled:** GIO	**SPICS enabled:** Receives the CS signal from the external master

NOTE:

1. When the SPICS signals are disabled, the chip-select field in the transmit data is not used.
2. When the SPIENA signal is disabled, the $\overline{\text{SPIENA}}$ pin is ignored in master mode, and not driven as part of the SPI transaction in slave mode.

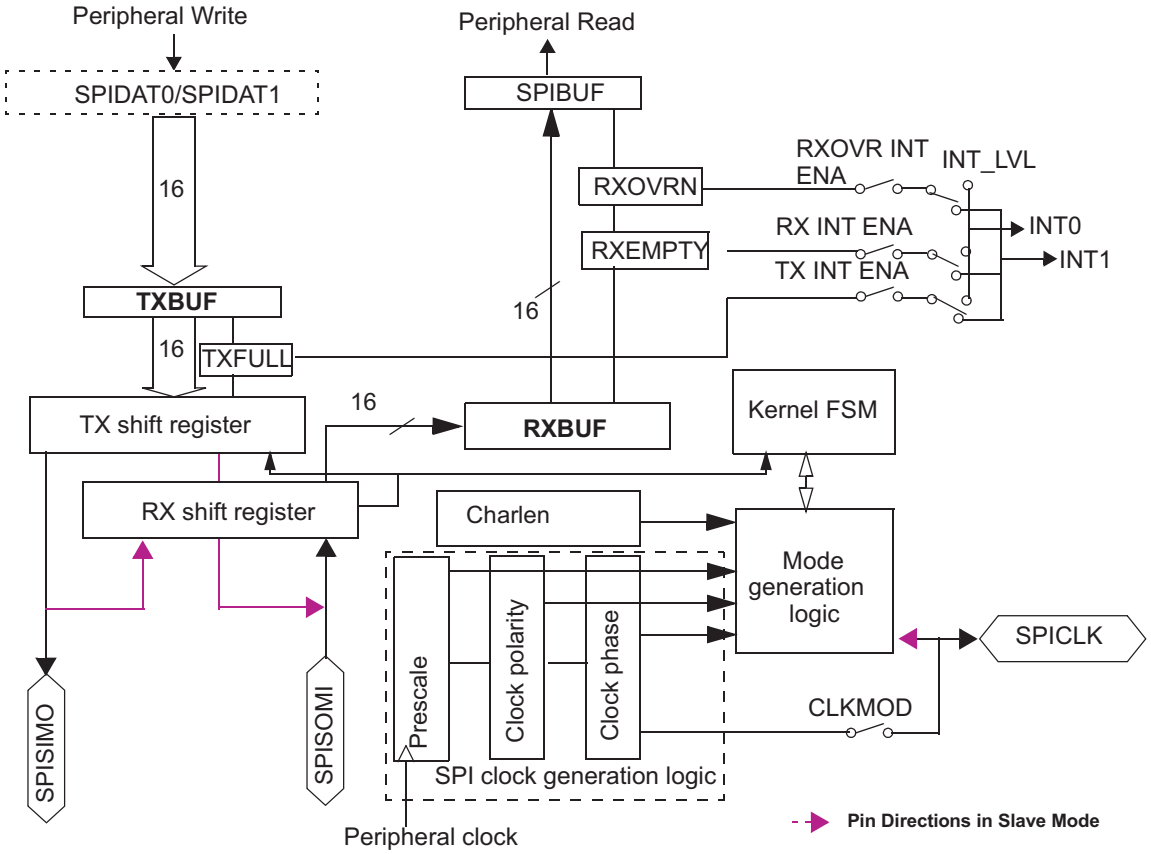
28.2 Basic Operation

This section details the basic operation principle of the SPI mode and the MibSPI mode operation of the device.

28.2.1 SPI Mode

The SPI can be configured via software to operate as either a master or a slave. The MASTER bit (SPIGCR1[0]) selects the configuration of the SPISIMO and SPISOMI pins. CLKMOD bit (SPIGCR1[1]) determines whether an internal or external clock source will be used.

The slave chip select ($\overline{\text{SPICS}}$) pins are used when communicating with multiple slave devices or, with a single slave, to delimit messages containing a leading register address. When a write occurs to SPIDAT1 in master mode, the $\overline{\text{SPICS}}$ pins are automatically driven to select the specified slave.



Handshaking mechanism, provided by the $\overline{\text{SPIENA}}$ pin, enables a slave SPI to delay the generation of the clock signal supplied by the master if it is not prepared for the next exchange of data.

28.2.1.1 SPI Mode Operation Block Diagram

Figure 28-1 shows the SPI transaction hardware. TXBUF and RXBUF are internal buffers that are intended to improve the overall throughput of data transfer. TXBUF is a transmit buffer, while RXBUF is a receive buffer.

Copyright © 2018, Texas Instruments Incorporated

Figure 28-1. SPI Functional Logic Diagram

1 This is a representative diagram, which shows three-pin mode hardware.
2 TXBUF, RXBUF, and SHIFT_REGISTER are user-invisible registers.
3 SPIDAT0 and SPIDAT1 are user-visible, and are physically mapped to the contents of TXBUF.
4 SPISIMO, SPISOMI, SPICLK pin directions depend on the Master or Slave Mode.

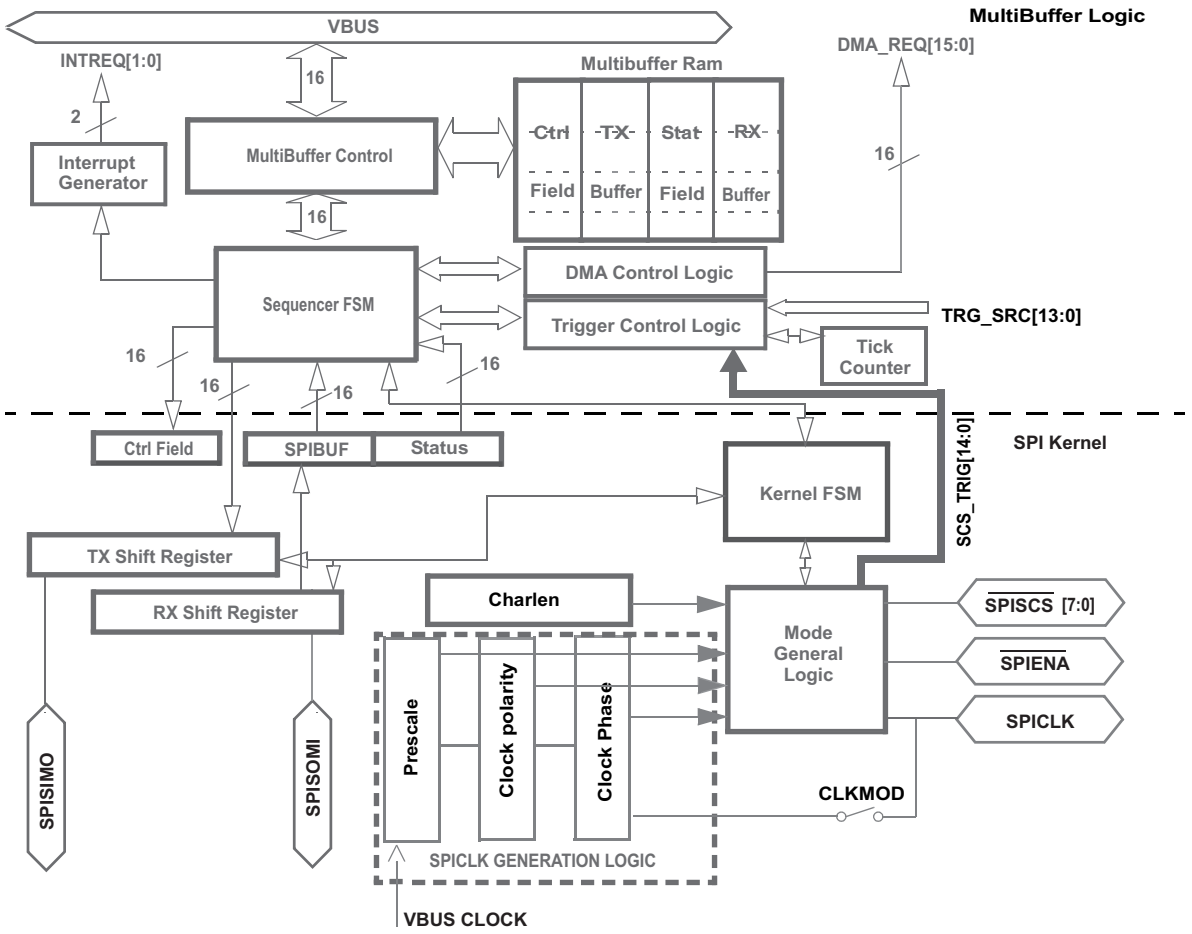
28.2.1.2 Data Flow and Handling for TX and RX

28.2.1.2.1 Data Sequencing when SPIDAT0 or SPIDAT1 is Written

- If both the TX shift register and TXBUF are empty, then the data is directly copied to the TX shift register. For devices with DMA, if DMA is enabled, a transmit DMA request (TX_DMA_REQ) is generated to cause the next word to be fetched. If transmit interrupts are enabled, a transmitter-empty interrupt is generated.
- If the TX shift register is already full or is in the process of shifting and if TXBUF is expty then the data written to SPIDAT0 / SPIDAT1 is copied to TXBUF and TXFULL flag is set to 1 at the same time.
- When a shift operation is complete, data from the TXBUF (if it is full) is copied into TX shift register and the TXFULL flag is cleared to 0 to indicate that next data can be fetched. A transmit DMA request (if enabled) or a transmitter-empty interrupt (if enabled) is generated at the same time.

Copyright © 2018, Texas Instruments Incorporated

28.2.1.2.2 Data Sequencing when All Bits Shifted into RXSHIFT Register



- If both SPIBUF and RXBUF are empty, the received data in RX shift register is directly copied into SPIBUF and the receive DMA request (if enabled) is generated and the receive-interrupt (if enabled) is generated. The RXEMPTY flag in SPIBUF is cleared at the same time.
- If SPIBUF is already full at the end of receive completion, the RX shift register contents is copied to RXBUF. A receive DMA request is generated, if enabled. The receive complete interrupt line remains high.
- If SPIBUF is read by the CPU or DMA and if RXBUF is full, then the contents of RXBUF are copied to SPIBUF as soon as SPIBUF is read. RXEMPTY flag remains cleared, indicating that SPIBUF is still full.
- If both SPIBUF and RXBUF are full, then RXBUF will be overwritten and the RXOVR interrupt flag is set and an interrupt is generated, if enabled.

NOTE: Prefetching is done only in Master mode. In Slave mode, since the TG to be serviced is known only after a valid ChipSelect assertion, no prefetching is done.

28.2.2 MibSPI Mode

Figure 28-2 shows multi-buffered mode operation. In Multi-buffer mode the transmit data has to be written to the TXRAM locations and the receive data has to be read from RXRAM locations of the multi-buffer RAM. A MibSPI supports up to 256 locations each for Transmit and Receive Data.

Figure 28-2. MibSPI Functional Logic Diagram

Copyright © 2018, Texas Instruments Incorporated

28.2.2.1 Data Handling for TX and RX Transfer Groups

28.2.2.1.1 Data Sequencing of a Transmit Data

In multi-buffer mode, any buffer that needs to be transmitted over by the SPI, should be associated with a Transfer Group. Each TG (Transfer Group) will have a Trigger Source based on which it'll be triggered. Once a TG is triggered, the buffers belonging to it will be transmitted.

Sequencer (FSM) controls the data flow from the multi-buffer RAM to the Shift Register. The Multi-buffer Control Logic has arbitration logic between VBUS and the Sequencer accessing the multi-buffer RAM. Sequencer picks up a highest priority Transfer Group from among the active TGs to be serviced. For the selected TG the starting buffer to be transferred is obtained from the PSTART of the respective TGxCTRL register.

Sequencer requests for the selected buffer through the Multi-buffer Control Logic, and once it receives the data, it reads the control fields to determine the subsequent action. Once the buffer is determined to be ready for transfer, the data is written to the TX SHIFT REGISTER by the Sequencer. This triggers the Kernel FSM to initiate the SPI transfer.

Once the Sequencer is finished writing to the TX SHIFT REGISTER, it prefetches the next buffer to be transferred from the multi-buffer RAM and stores the Data.

Once the Sequencer is finished writing to the TX SHIFT REGISTER, it prefetches the next buffer to be transferred from the multi-buffer RAM and stores the Data.

Sequencer writes the prefetched Transmit Data to the Shift Register immediately upon request by the Kernel. This way, the throughput of the SPI transfer is increased in Master mode of operation. In case of Slave mode, after the Receive data is copied to the RX RAM, Sequencer waits for the next active Chip Select trigger to fetch the next data.

28.2.2.1.2 Data Sequencing of the Received Data

At the end of a SPI transfer, the received Data is copied to SPIBUF register and then forwarded to the Sequencer. The Sequencer then, requests the Multi-buffer Control Logic to write the received data to the respective RXRAM location. Along with Received Data, the Status fields like Transmission Error Flags and the Last Chip Select Number (LCSNR) are forwarded to be updated in the Status Field of the RXRAM.

Sequencer clears the RXEMPTY bit while writing a new Received Data in the RXRAM. If the RXEMPTY bit is already 0, then the Sequencer sets the RCVR_OVRN bit to 1 to indicate that this particular location has been overwritten in the RXRAM.

28.2.3 DMA Requests

In order to reduce CPU overhead in handling SPI message traffic on a character-by-character basis, SPI can use the DMA controller to transfer the data

28.2.3.1 SPI/MibSPI Compatibility Mode DMA Requests

. The DMA request enable bit (DMA REQ EN) controls the assertion of requests to the DMA controller module. When a character is being transmitted or received, the SPI will signal the DMA via the DMA request signals, TX_DMA_REQ and RX_DMA_REQ. The DMA controller will then perform the required data transfer.

For efficient behavior during DMA operations, the transmitter empty and receive-buffer full interrupts can be disabled. For specific DMA features, see the DMA controller specification.

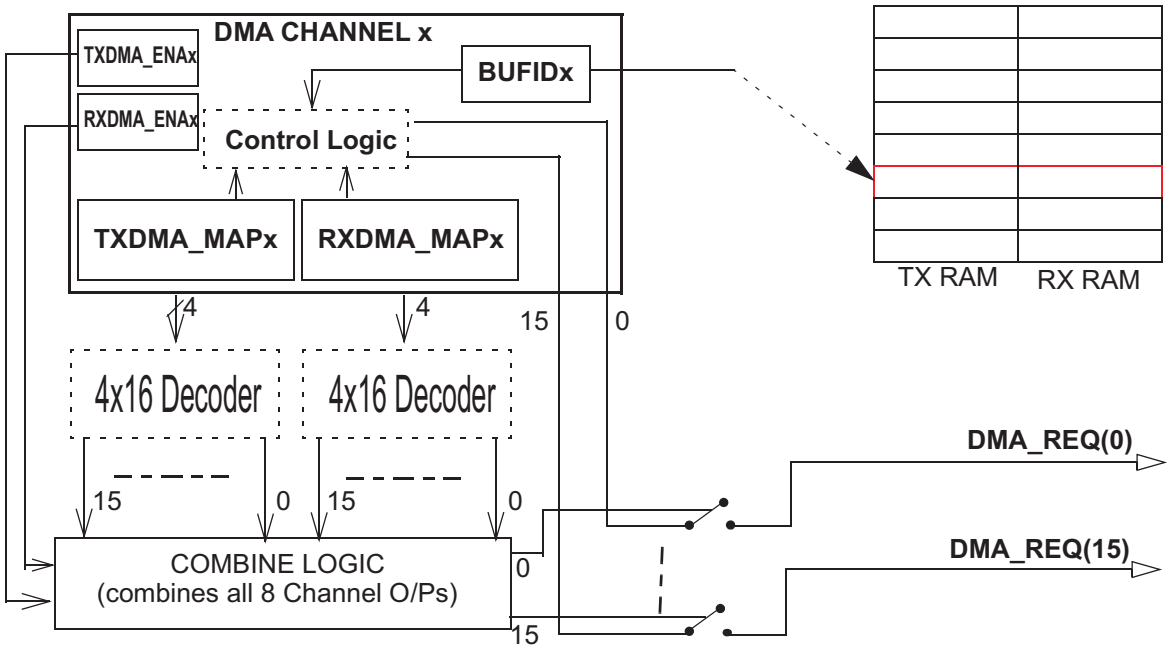
The SPI generates a request on the TX_DMA_REQ line each time the TX data is copied to the TX shift register either from the TXBUF or from peripheral data bus (when TXBUF is empty).

The first TX_DMA_REQ pulse is generated when either of the following is true:

- DMA REQ EN (SPIINT0[16]) is set to 1 while SPIEN (SPIGCR1[24]) is already 1.
- SPIEN (SPIGCR1[24]) is set to 1 while DMA REQ EN (SPIINT0[16]) is already 1.

Copyright © 2018, Texas Instruments Incorporated

The SPI generates a request on the RX_DMA_REQ line each time the received data is copied to the SPIBUF.



28.2.3.2 DMA in Multi-Buffer Mode

The MibSPI provides sophisticated programmable DMA control logic that completely eliminates the necessity of CPU intervention for data transfers, once programmed. When the multi-buffer mode is used, the DMA enable bit in the SPIINT0 register is ignored. DMA source or destination should be only the multi-buffer RAM and not SPIDAT0 / SPIDAT1 or SPIBUF register as in case of compatibility mode DMA.

The MibSPI offers up to eight DMA channels (for SEND and RECEIVE). All of the DMA channels are programmable individually and can be hooked to any buffer. The MibSPI provides up to 16 DMA request lines, and DMA requests from any channel can be programmed to be routed through any of these 16 lines. A DMA transfer can trigger both transmit and receive.

Each DMA channel has the capability to transfer a block of up to 32 data words without interruption using only one buffer of the array by configuring the DMAxCTRL register. Using the DMAxCOUNT and DMACTNTLEN register, up to 65535 (64K) words of data can be transferred without any interruption using just one buffer of the array. This enables the transfer of memory blocks from or into an external SPI memory.

Figure 28-3. DMA Channel and Request Line (Logical) Structure in Multi-buffer Mode

28.2.4 Interrupts

There are two levels of vectorized interrupts supported by the SPI. These interrupts can be caused under the following circumstances:

- Transmission error
- Receive overrun
- Receive complete (receive buffer full)
- Transmit buffer empty

These interrupts may be enabled or disabled via the SPIINT0 register.

During transmission, if one of the following errors occurs: BITERR, DESYNC, DLENERR, PARITYERR, or TIMEOUT, the corresponding bit in the SPIFLG register is set. If the corresponding enable bit is set, then an interrupt is generated. The level of all the above interrupts is set by the bit fields in the SPILVL register.

The error interrupts are enabled and prioritized independently from each other, but the interrupt generated will be the same if multiple errors are enabled on the same level. The SPIFLG register should be used to determine the actual cause of an error.

NOTE: Since there are two interrupt lines, one each for Level 0 and Level 1, it is possible for a programmer to separate out the interrupts for receive buffer full and transmit buffer empty. By programming one to Level 0 and the other to Level 1, it is possible to avoid a check on whether an interrupt occurred for transmit or for receive. A programmer can also choose to group all of the error interrupts into one interrupt line and both TX-empty and RX-full interrupts into another interrupt line using the LVL control register. In this way, it is possible to separate error-checking from normal data handling.

28.2.4.1 Interrupts in Multi-Buffer Mode

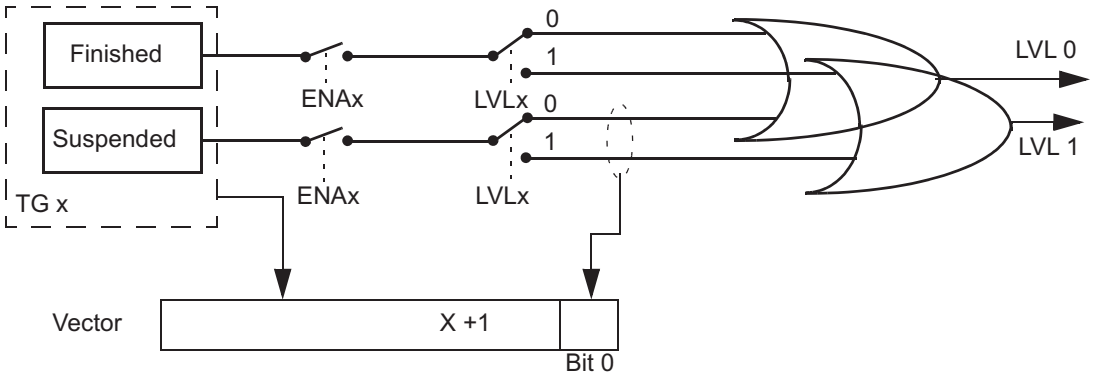
In multi-buffer mode, the SPI can generate interrupts on two levels.

In normal multi-buffer operation, the receive and transmit are not used and therefore the enable bits of SPIINT0 are not used.

The interrupts available in multi-buffer mode are:

- Transmission error interrupt
- Receive overrun interrupt
- TG suspended interrupt
- TG completed interrupt

When a TG has finished and the corresponding enable bit in the TGINTENA register is set, a transfer-finished interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.



When a TG is suspended by a buffer that has been set as suspend to wait until TXFULL flag or/and RXEMPTY flag are set, and if the corresponding bit in the TGINTENA register is set, an transfer-suspended interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

Figure 28-4 illustrates the TG interrupts.

During transmission, if one of the following errors occurs, BITERR, DESYNC, PARITYERR, TIMEOUT, DLENERR, the corresponding flag in the SPIFLG register is set. If the enable bit is set, then an interrupt is generated. The level of the interrupts could be generated according to the bit field in SPILVL register.

Copyright © 2018, Texas Instruments Incorporated

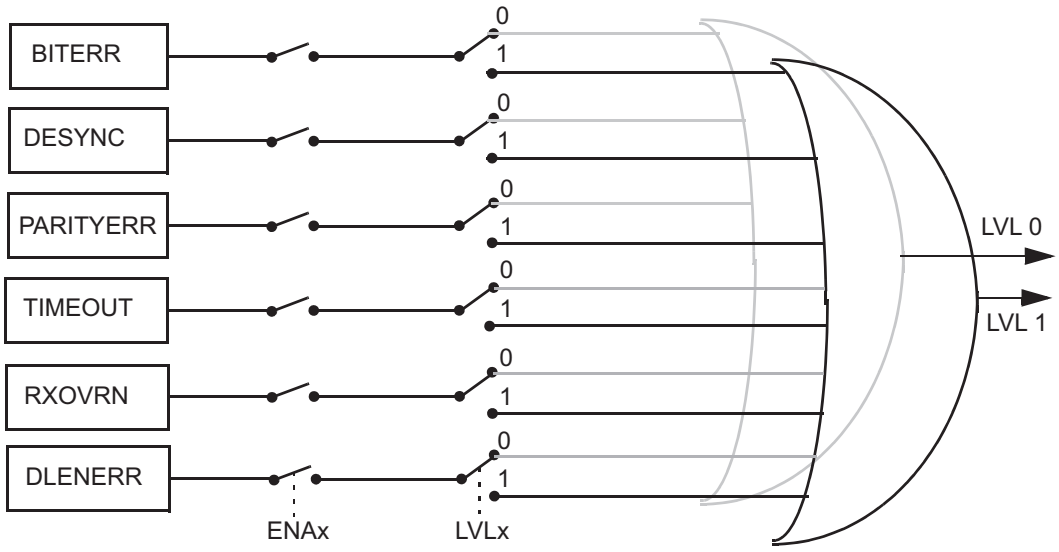


Figure 28-4. TG Interrupt Structure

The RXOVRN interrupt is generated when a buffer in the RXRAM is overwritten by a new received word. While writing newly received data to a RXRAM location, if the RXEMPTY bit of the corresponding location is 0, then the RXOVR bit will be set to 1 during the write operation, so that the buffer starts to indicate an overrun. This RXOVR flag is also reflected in SPIFLG register as RXOVRNINTFLG and the corresponding vector number is updated in TGINTVECT0/TGINTVECT1 register. If an overrun interrupt is enabled, then an interrupt will be generated indicating an overrun condition.

The error interrupts are enabled and prioritized independently from each other, but the vector generated by the SPI will be the same if multiple errors are enabled on the same level.

Figure 28-5. SPIFLG Interrupt Structure

Since the priority of an error interrupt is lower than a completion/suspend interrupt for a TG, the interrupts can be split into two levels. By programming all the error interrupts into Level 0 and TG-complete / TG-suspend interrupts into Level 1, it is possible to get a clear indication of the source of error interrupts. However, when a vector register shows an error interrupt, the actual buffer for which the error has occurred is not readily identifiable. Since each buffer in the multi-buffer RAM is stored along with its individual status flags, each buffer should be read until a buffer with any error flag set is found.

A separate interrupt line is provided to indicate the uncorrectable error condition in the MibSPI. This line is available (and valid) only in the multi-buffer mode of the MibSPI module and if the parity error detection feature for multi-buffer RAM is enabled.

28.2.5 Physical Interface

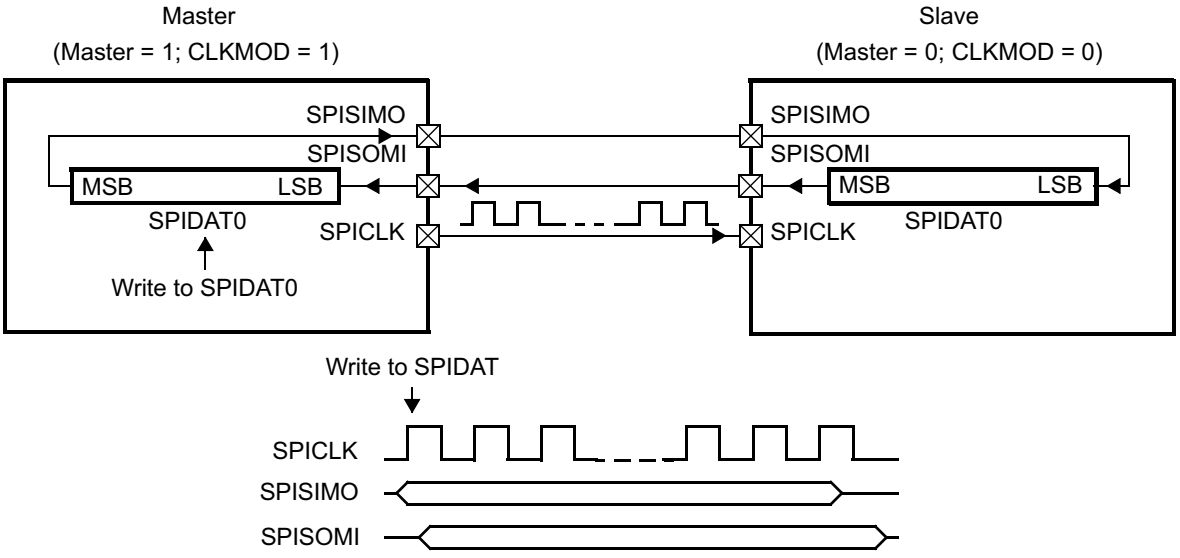
The SPI can be configured via software to operate as either a master or a slave. The MASTER bit (SPIGCR1[0]) selects the configuration of the SPISIMO and SPISOMI pins. The CLKMOD bit (SPIGCR1[1]) determines whether an internal or external clock source is used.

The slave chip select ($\overline{\text{SPICS}}$) pins, are used when communicating with multiple slave devices. When the a write occurs to SPIDAT1 in master mode, the $\overline{\text{SPICS}}$ pins are automatically driven to select the specified slave.

Handshaking mechanism, provided by the $\overline{\text{SPIENA}}$ pin, enables a slave SPI to delay the generation of the clock signal supplied by the master if it is not prepared for the next exchange of data.

28.2.5.1 Three-Pin Mode

In master mode configuration (MASTER = 1 and CLKMOD = 1), the SPI provides the serial clock on the SPICLK pin. Data is transmitted on the SPISIMO pin and received on the SPISOMI pin (see Figure 28-6).



Data written to the shift register (SPIDAT0 / SPIDAT1) initiates data transmission on the SPISIMO pin, MSB first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB of the SPIDAT0 register. When the selected number of bits have been transmitted, the received data in the shift register is transferred to the SPIBUF register for the CPU to read. Data is stored right-justified in SPIBUF.

See Section 28.2.1.2.2 and Section 28.2.2 for details about the data handling for transmit and receive operations.

In slave mode configuration (MASTER = 0 and CLKMOD = 0), data shifts out on the SPISOMI pin and in on the SPISIMO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock.

Data written to the SPIDAT0 or SPIDAT1 register is transmitted to the network when the SPICLK signal is received from the network master. To receive data, the SPI waits for the network master to send the SPICLK signal and then shifts data on the SPISIMO pin into the RX shift register. If data is to be transmitted by the slave simultaneously, it must be written to the SPIDAT0 or SPIDAT1register before the beginning of the SPICLK signal.

Figure 28-6. SPI Three-Pin Operation

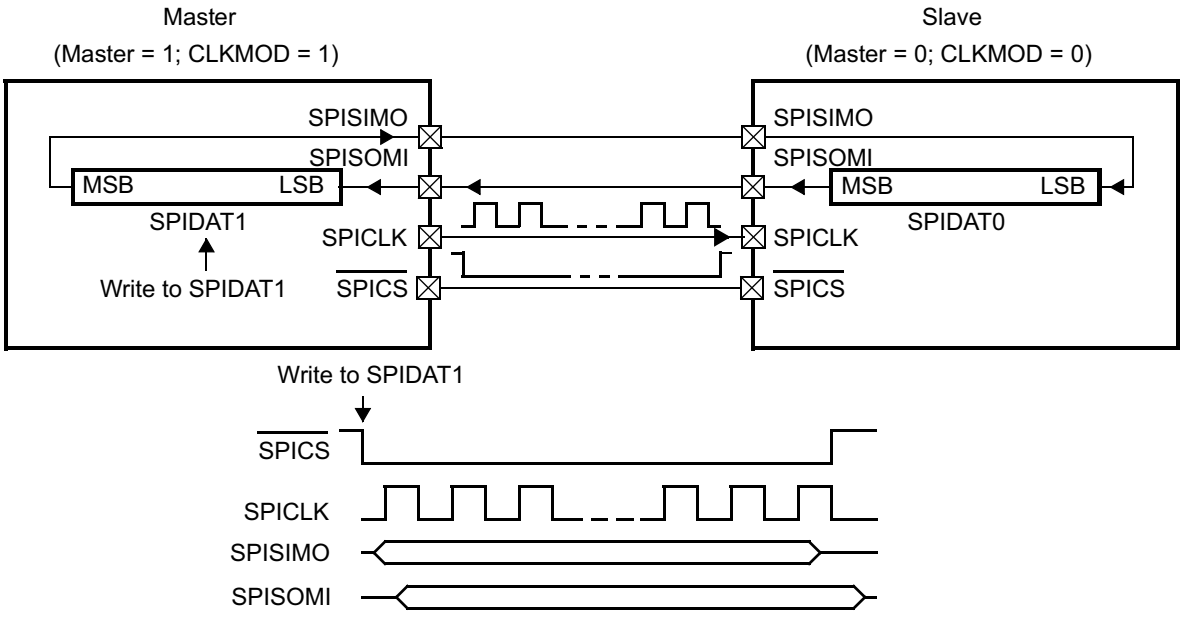
Copyright © 2018, Texas Instruments Incorporated

28.2.5.2 Four-Pin Mode with Chip Select

The three-pin option and the four-pin option of the SPI / MibSPI are identical in the master mode (CLKMOD = 1), except that the four-pin option uses either $\overline{\text{SPIENA}}$ or $\overline{\text{SPICS}}$ pins. The I/O directions of these pins are determined by the CLKMOD control bit as SPI / MibSPI and is not general-purpose I/O.

28.2.5.2.1 Four-Pin Option with $\overline{\text{SPICS}}$

In master mode, each chip select signal is used to select a specific slave. In slave mode, the chip select signal is used to enable and disable the transfer. Chip-select functionality is enabled by setting one of the $\overline{\text{SPICS}}$ pins as a chip select. It is disabled by setting all $\overline{\text{SPICS}}$ pins as GIOs in SPIPC0.



28.2.5.2.1.1 Multiple Chip Selects

The $\overline{\text{SPICS}}$ pins that are used must be configured as functional pins in the SPIPC0 register. The default pattern to be put on the $\overline{\text{SPICS}}$ when all the slaves are deactivated is set in the SPIDEF register. This pattern allows different slaves with different chip-select polarity to be activated by the SP/MibSPI.

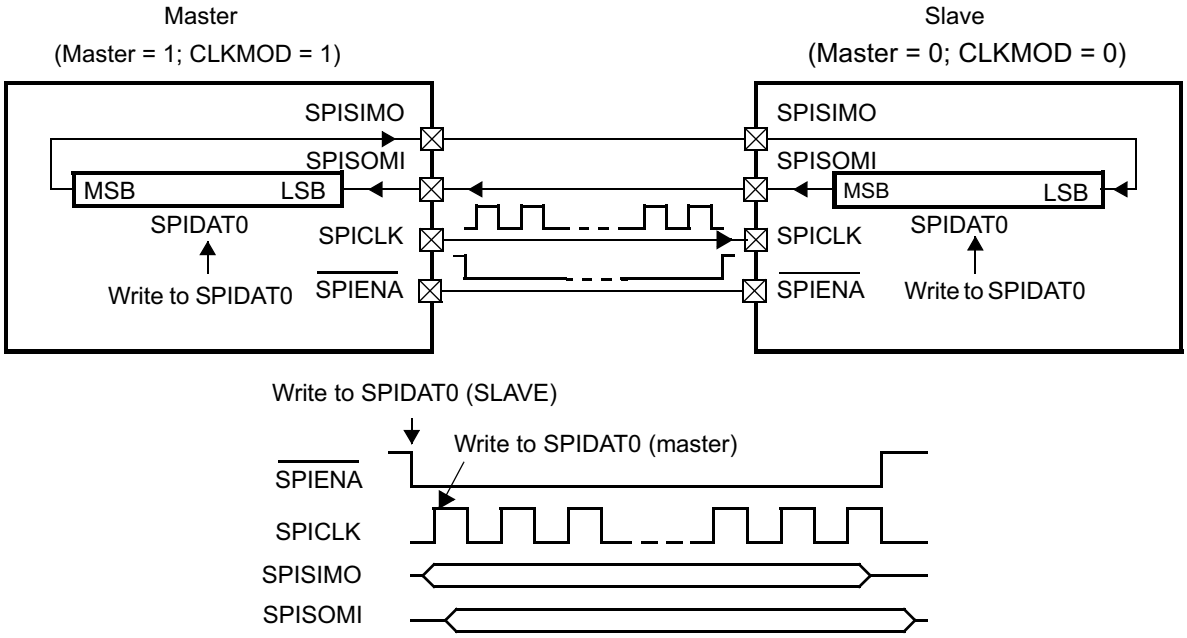
The master-mode SPI is capable of driving either 0 or 1 as the active value for any $\overline{\text{SPICS}}$ output pin. The drive state for the $\overline{\text{SPICS}}$ pins is controlled by the CSNR field of SPIDAT1. The pattern that is driven will select the slave to which the transmission is dedicated.

In slave mode, the SPI can only be selected by an active value of 0 on any of its selected $\overline{\text{SPICS}}$ input pins.

Figure 28-7. Operation with $\overline{\text{SPICS}}$

Copyright © 2018, Texas Instruments Incorporated

28.2.5.2.2 Four-Pin Option with $\overline{\text{SPIENA}}$



The $\overline{\text{SPIENA}}$ operates as a WAIT signal pin. For both the slave and the master, the $\overline{\text{SPIENA}}$ pin must be configured to be functional (SPIPC0[8] = 1). In this mode, an active-low signal from the slave on the $\overline{\text{SPIENA}}$ pin allows the master SPI to drive the clock pulse stream. A high signal tells the master to hold the clock signal (and delay SPI activity).

If the $\overline{\text{SPIENA}}$ pin is in high-impedance mode (ENABLE_HIGHZ = 1), the slave will put $\overline{\text{SPIENA}}$ into the high-impedance once it completes receiving a new character. If the $\overline{\text{SPIENA}}$ pin is in push-pull mode (ENABLE_HIGHZ = 0), the slave will drive $\overline{\text{SPIENA}}$ to 1 once it completes receiving a new character. The slave will drive $\overline{\text{SPIENA}}$ low again for the next word to transfer, after new data is written to the slave TX shift register.

In master mode (CLKMOD = 1), if the $\overline{\text{SPIENA}}$ pin is configured as functional, then the pin acts as an input pin. If configured as a slave SPI and as functional, the $\overline{\text{SPIENA}}$ pin acts as an output pin.

NOTE: During a transfer, if a slave-mode SPI detects a deassertion of its chip select before its internal character length counter overflows, then it places SPISOMI and $\overline{\text{SPIENA}}$ (if ENABLE_HIGHZ bit is set to 1) in high-impedance mode. Once this condition has occurred, if a SPICLK edge is detected while the chip select is deasserted, then the SPI stops that transfer and sets an DLENERR error flag and generates an interrupt (if enabled).

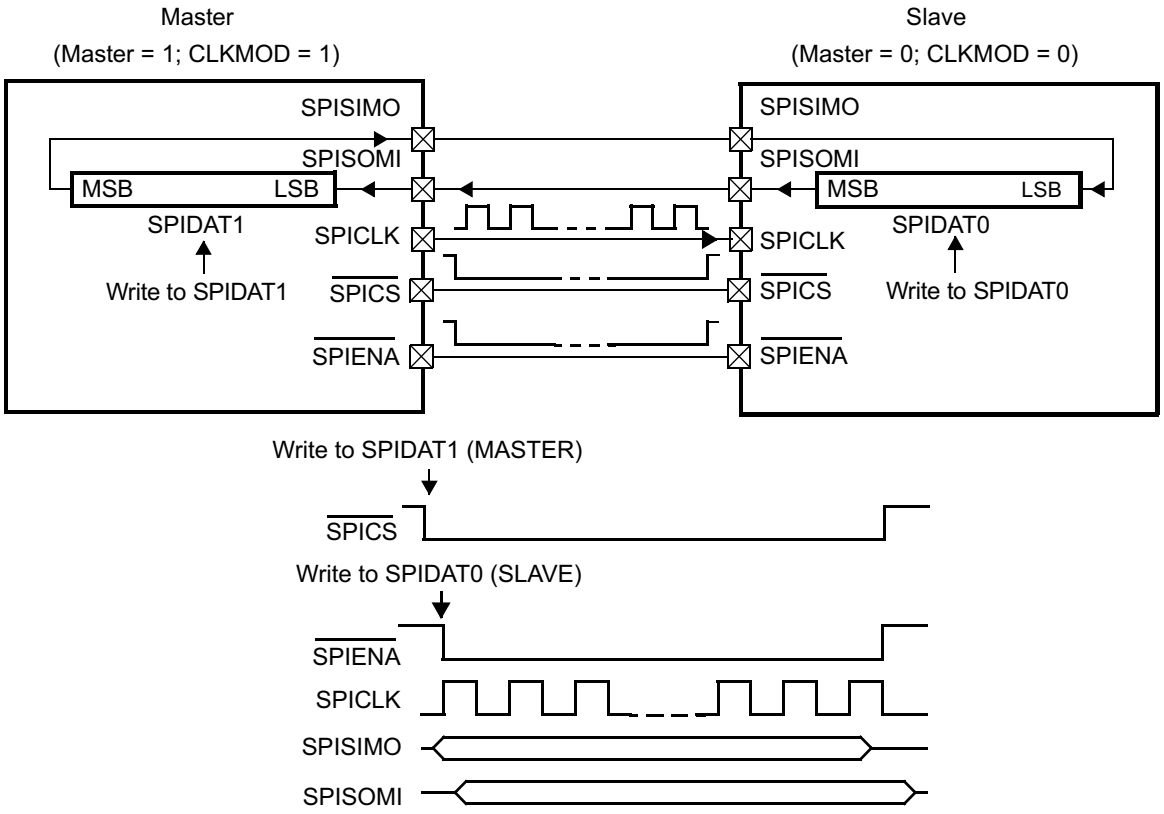
Figure 28-8. Operation with $\overline{\text{SPIENA}}$

Copyright © 2018, Texas Instruments Incorporated

28.2.5.3 Five-Pin Operation (Hardware Handshaking)

Five-pin operation combines the functionality of three-pin mode, plus the enable pin and one or more chip select pins. The result is full hardware handshaking. To use this mode, both the SPIENA pin and the required number of SPICS pins must be configured as functional pins.

If the SPIENA pin is in high-impedance mode (ENABLE_HIGHZ = 1), the slave SPI will put this signal into the high-impedance state by default. The slave will drive the signal SPIENA low when new data is written to the slave shift register and the slave has been selected by the master (SPICS is low).



If the SPIENA pin is in push-pull mode (ENABLE_HIGHZ = 0), the slave SPI drives this pin high by default when it is in functional mode. The slave SPI will drive the SPIENA signal low when new data is written to the slave shift register (SPIDAT0/SPIDAT1) and the slave is selected by the master (SPICS is low). If the slave is deselected by the master (SPICS goes high), the slave SPIENA signal is driven high.

NOTE: Push-pull mode of the SPIENA pin can be used only when there is a single slave in the system. When multiple SPI slave devices are connected to the common SPIENA pin, all of the slaves should configure their SPIENA pins in high-impedance mode.

In master mode, if the SPICS pins are configured as functional pins, then the pins will be in output mode. A write to the master's SPIDAT1/SPIDAT0 register will automatically drive the SPICS signals low. The master will drive the SPICS signals high again after completing the transfer of the bits of the data.

In slave mode (CLKMOD = 0), the SPICS pins act as SPI functional inputs.

Figure 28-9. SPI Five-Pin Option with SPIENA and SPICS

28.2.6 Advanced Module Configuration Options

28.2.6.1 Data Formats

To support multiple different types of slaves in one SPI network, four independent data word formats are implemented that allow configuration of individual data word length, polarity, phase, and bit rate. Each word transmitted can select which data format to use via the bits DFSEL[1:0] in its control field from one of the four data word formats. Same data format can be supported on multiple chip selects.

Data formats 0, 1, 2, and 3 can be configured through SPIFMTx control registers.

Each SPI data format includes the standard SPI data format with enhanced features:

- Individually-configurable shift direction can be used to select MSB first or LSB first, whereas the position of the MSB depends on the configured data word length.
- Receive data is automatically right-aligned, independent of shift direction and data word length. Transmit data has to be written right-aligned into the SPI and the internal shift register will transmit according to the selected shift direction and data word length for correct transfer.
- To increase fault detection of data transmission and reception, an odd or even parity bit can be added at the end of a data word. The parity generator can be enabled or disabled individually for each data format. If a received parity bit does not match with the locally calculated parity bit, the parity error flag (PARITYERR) is set and an interrupt is asserted (if enabled).

Since the master-mode SPI can drive two consecutive accesses to the same slave, an 8-bit delay counter is available to satisfy the delay time for data to be refreshed in the accessed slave. The delay counter can be programmed as part of the data format.

CHARLEN[4:0] specifies the number of bits (2 to 16) in the data word. The CHARLEN[4:0] value directs the state control logic to count the number of bits received or transmitted to determine when a complete word is transferred.

Data word length **must** be programmed to the same length for both the **master** and the **slave**. However, when chip selects are used, there may be multiple targets with different lengths in the system.

NOTE: Data must be right-justified when it is written to the SPI for transmission irrespective of its character length or word length.

Figure 28-10 shows how a 12-bit word (0xEC9) needs to be written to the transmit buffer to be transmitted correctly.

Figure 28-10. Format for Transmitting an 12-Bit Word

D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
x	x	x	x	1	1	1	0	1	1	0	0	1	0	0	1

NOTE: The received data is always stored right-justified regardless of the character length or direction of shifting and is padded with leading 0s when the character length is less than 16 bits.

Figure 28-11 shows how a 10-bit word (0x0A2) is stored in the buffer once it is received.

Figure 28-11. Format for Receiving an 10-Bit Word

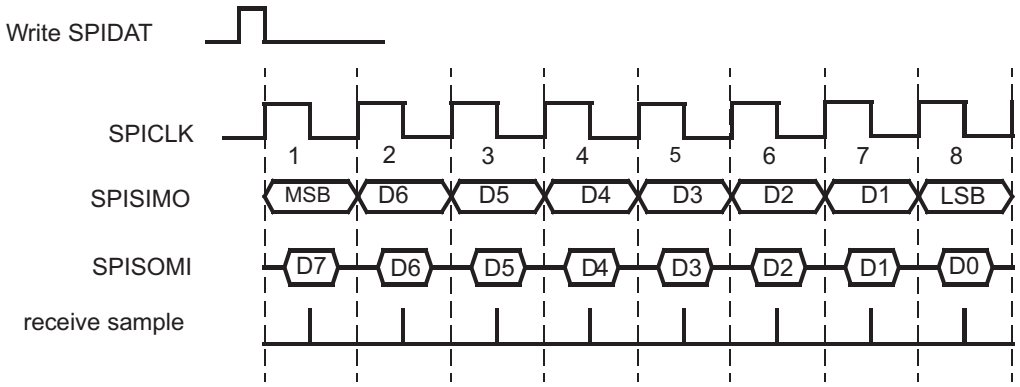
28.2.6.2 Clocking Modes

SPICLK may operate in four different modes, depending on the choice of phase (delay/no delay) and the polarity (rising edge/falling edge) of the clock.



The data input and output edges depend on the values of both POLARITY and PHASE as shown in Table 28-3.

Table 28-3. Clocking Modes

POLARITY	PHASE	Action
0	0	Data is output on the rising edge of SPICLK. Input data is latched on the falling edge.
0	1	Data is output one half-cycle before the first rising edge of SPICLK and on subsequent falling edges. Input data is latched on the rising edge of SPICLK.
1	0	Data is output on the falling edge of SPICLK. Input data is latched on the rising edge.
1	1	Data is output one half-cycle before the first falling edge of SPICLK and on subsequent rising edges. Input data is latched on the falling edge of SPICLK.

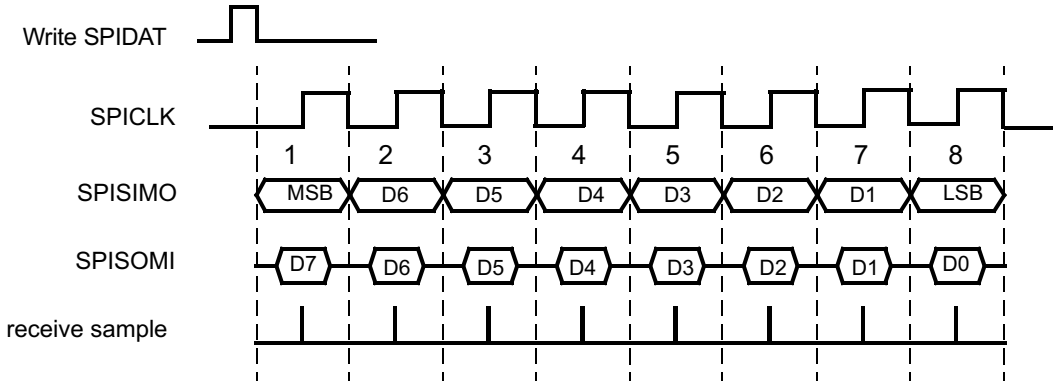


Figure 28-12 to Figure 28-15 illustrate the four possible configurations of **SPICLK** corresponding to each mode. Having four signal options allows the SPI to interface with many different types of serial devices.

Figure 28-12. Clock Mode with Polarity = 0 and Phase = 0

Data is output on the rising edge of SPICLK.
Input data is latched on the falling edge of SPICLK.

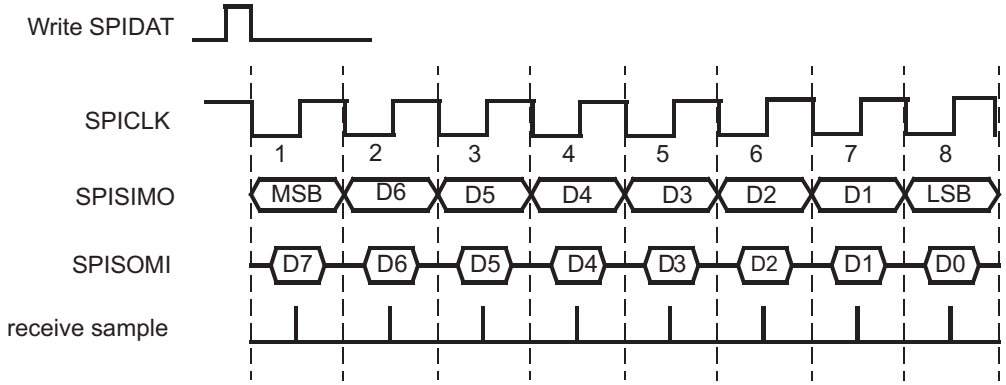

Figure 28-13. Clock Mode with Polarity = 0 and Phase = 1

28.2.6.3 Decoded and Encoded Chip Select (Master Only)

In this device, the SPI can connect to up to 6 individual slave devices using chip-selects by routing one wire to each slave. The 6 chip selects in the control field are directly connected to the 6 pins. The default value of each chip select (not active) can be configured via the register CSDEF. During a transmission, the value of the chip select control field (CSNR) of the SPIDAT1 register is driven on the $\overline{\text{SPICS}}$ pins. When the transmission finishes, the default chip-select value (defined by the CSDEF register) is put on the $\overline{\text{SPICS}}$ pins.

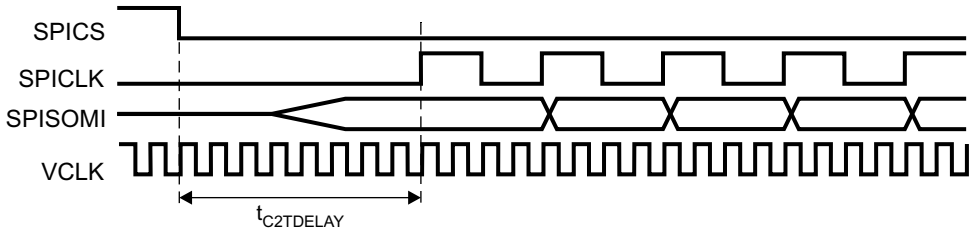
The SPI can support more than 6 slaves by using encoded chip selects. To connect the SPI with encoded slaves devices, the CSNR field allows multiple active $\overline{\text{SPICS}}$ pins at the same time, which enables encoded chip selects from 0 to 16. To use encoded chip selects, all 6 chip select lines have to be connected to each slave device and each slave needs to have a unique chip-select address. The CSDEF register is used to provide the address at which slaves devices are all de-selected.

Users can combine decoded and encoded chip selects. For example, *n* $\overline{\text{SPICS}}$ pins can be used for encoding an *n*-bit address and the remaining pins can be connected to decoded-mode slaves.

28.2.6.4 Chip Select Timing Control

This section describes fields of the control register SPIDELAY. This register decides the chip select and timing control for the device.

28.2.6.4.1 Chip-Select-Active-to-Transmit-Start-Delay (C2TDELAY)



C2TDELAY is used in master mode only. It defines a setup time for the slave device that delays the data transmission from the chip select active edge by a multiple of VCLK cycles. Chip Select-active-to-transmission delays between 2 to 257 VCLK cycles can be achieved.

The setup time value is calculated as:

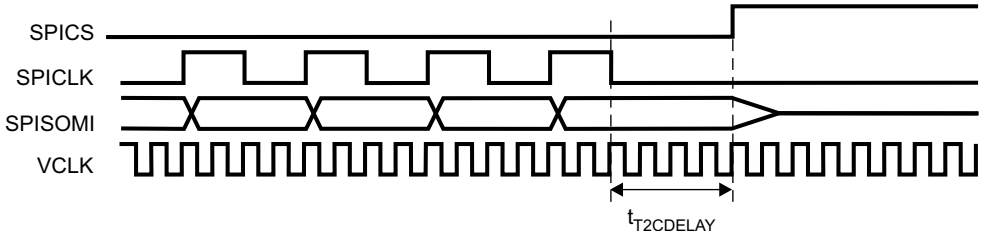
$t_{C2TDELAY}$ = (C2TDELAY + 2) × VCLK Period

Figure 28-17 is the timing diagram when C2TDELAY of 8 VCLK Cycles.

Figure 28-17. Example: $t_{C2TDELAY}$ = 8 VCLK Cycles

Copyright © 2018, Texas Instruments Incorporated

28.2.6.4.2 Transmit-End-to-Chip-Select-Inactive-Delay (T2CDELAY)



T2CDELAY is used in master mode only. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of VCLK cycles after the last bit is transferred. T2CDELAY can be configured between 2 and 256 VCLK cycles.

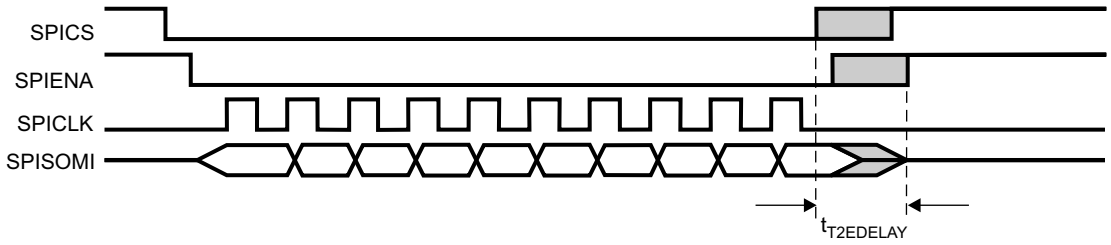
The hold time value is calculated as:

$t_{T2CDELAY}$= (T2CDELAY +1) × VCLK Period

Figure 28-18 is the timing diagram when T2CDELAY of 4 VCLK Cycles.

Figure 28-18. Example: $t_{T2CDELAY}$= 4 VCLK Cycles

28.2.6.4.3 Transmit-Data-Finished-to-ENA-Pin-Inactive-Time-Out (T2EDELAY)



T2EDELAY is used in master mode only. It defines a time-out value as a multiple of SPI clock before the ENAble signal has to become inactive and after the CS becomes inactive. The SPI clock depends on which data format is selected. If the slave device is missing one or more clock edges, it is becoming de-synchronized. Although the master has finished the data transfer the

The T2EDELAY defines a time-out value that triggers the DESYNC flag, if the ENA signal is not deactivated in time. DESYNC flag is set to indicate that the Slave device did not deassert its $\overline{\text{SPIENA}}$ pin in time to acknowledge that it has received all the bits of the sent character.

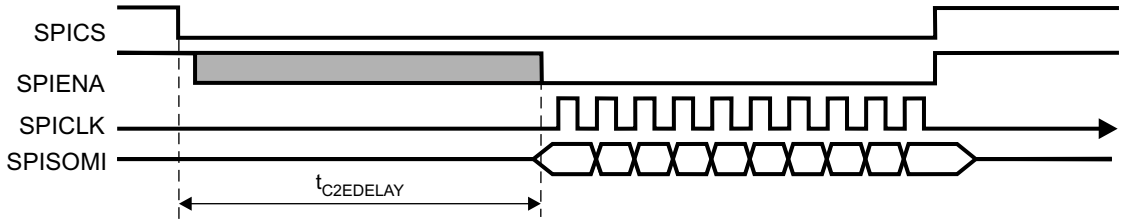
The timeout value is calculated as:

$t_{T2EDELAY}$ = T2EDELAY/SPIclock

Figure 28-19. Transmit-Data-Finished-to-ENA-Inactive-Timeout

NOTE: If T2CDELAY is programmed a non-zero value, then T2EDELAY will start only after the T2CDELAY completes. This should be taken into consideration to determine an optimum value of T2EDELAY.

Copyright © 2018, Texas Instruments Incorporated



28.2.6.4.4 Chip-Select-Active-to-ENA-Signal-Active-Time-Out (C2EDELAY)

C2EDELAY is used in master mode only and it applies only if the addressed slave generates an ENAble signal as a hardware handshake response. C2EDELAY defines the maximum time between the SPI / MibSPI activating the chip select signal and the addressed slave responding by activating the ENA signal. C2EDELAY defines a time-out value as a multiple of SPI clocks. The SPI clock depends on whether data format 0 or data format 1 is selected.

The timeout value is calculated as:

$t_{C2EDELAY}$ = C2EDELAY/SPIclock

Figure 28-20. Chip-Select-Active-to-ENA-Signal-Active-Timeout

NOTE:

- If the slave device is not responding with the ENA signal before the time-out value is reached, the TIMEOUT flag in SPIFLG register is set and an interrupt is asserted if enabled.
- If a time-out occurs the MibSPI clears the transmit request of the timed-out buffer, sets the TIMEOUT flag for the current buffer and continues with the transfer of the next buffer in the sequence that is enabled.
- If C2TDELAY is programmed a non-zero value, then C2EDELAY will start only after the C2TDELAY completes. This should be taken into consideration to determine an optimum value of C2EDELAY.

28.2.6.5 Multiple Transfers to Same Slave and Variable Chip Select Setup and Hold Timing

This section gives information on the variable chip select setup and it shows how the CSHOLD bit is used and how the multiple transfers to same slave is enabled in the device.

28.2.6.5.1 Variable Chip Select Setup and Hold Timing (Master Only)

In order to support slow slave devices, a delay counter can be configured to delay data transmission after the chip select is activated. A second delay counter can be configured to delay the chip select deactivation after the last data bit is transferred. Both delay counters are clocked with the peripheral clock (VCLK).

If a particular data format specifically does not require these additional set-up or hold times for the chip select pins, then they can be disabled in the corresponding SPIFMTx register.

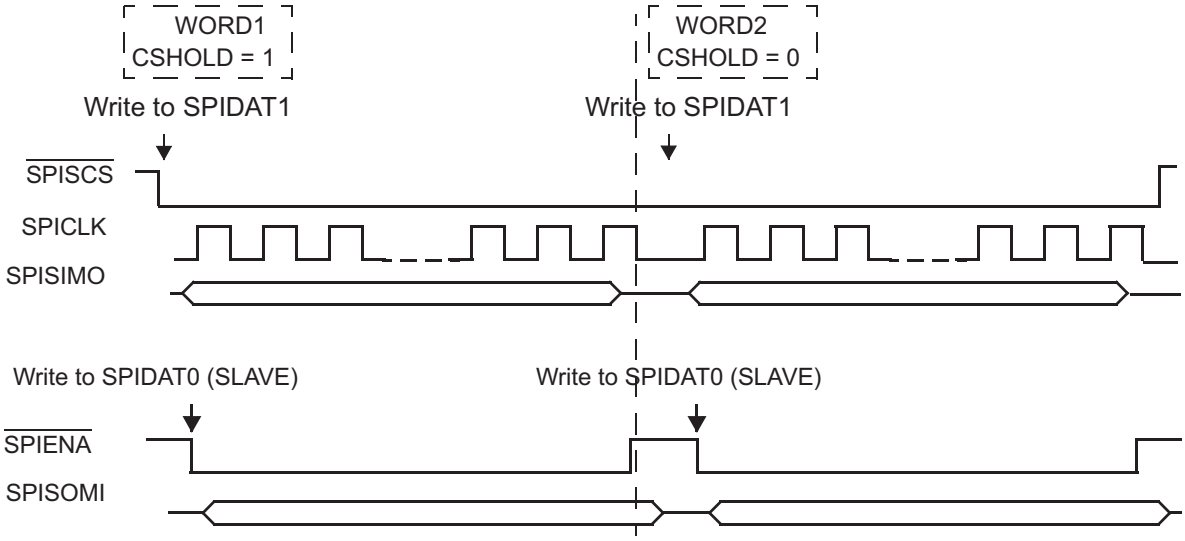
28.2.6.5.2 Hold Chip-Select Active

Some slave devices require the chip select signal to be held continuously active during several consecutive data word transfers. Other slave devices require the chip select signal to be deactivated between consecutive data word transfers.

CSHOLD is programmable in both master and slave modes of the multi-buffer mode of SPI. However, the meaning of CSHOLD in master mode and slave mode are different.

NOTE: If the CSHOLD bit is set within the current data control field, the programmed hold time and the following programmed set-up time will not be applied between transactions.

Copyright © 2018, Texas Instruments Incorporated



28.2.6.5.2.1 CSHOLD Bit in Master Mode

Each word in a master-mode SPI can be individually initialized for one of the two modes via the CSHOLD bit in its control field.

If the CSHOLD bit is set in the control field of a word, the chip select signal will not be deactivated until the next control field is loaded with new chip select information. Since the chip-select is maintained active between two transfers, the chip-select hold delay (T2CDELAY) is not applied at the end of the current transaction, and the chip-select set-up time delay (C2TDELAY) is not applied as well at the beginning of the following transaction. However, the wait delay (WDELAY) will be still applied between the two transactions, if the WDEL bit is set within the control field.

Figure 28-21 shows the SPI pins when a master-mode SPI transfers a word that has its CSHOLD bit set. The chip-select pins will not be deasserted after the completion of this word. If the next word to transmit has the same chip-select number (CSNR) value, the chip select pins will be maintained until the completion of the second word, regardless of whether the CSHOLD bit is set or not.

Figure 28-21. Typical Diagram when a Buffer in Master is in CSHOLD Mode (SPI-SPI)

28.2.6.5.2.2 CSHOLD Bit in Slave Mode (Multi-buffered Mode)

If the CSHOLD bit in a buffer is set to 1, then the MibSPI does not wait for the $\overline{\text{SPICS}}$ pins to be de-activated at the end of the shift operation to copy the received data to the receive RAM. With this feature, it is possible for a slave in multi-buffer mode to do multiple data transfers without requiring the $\overline{\text{SPICS}}$ pins to be deasserted between two buffer transfers.

If the CSHOLD bit in a buffer is cleared to 0 in a slave MibSPI, even after the shift operation is done, the MibSPI waits until the $\overline{\text{SPICS}}$ pin (if functional) is deasserted to copy the received data to the RXRAM.

If the CSHOLD bit is maintained as 0 across all the buffers, then the slave in multi-buffer mode requires its $\overline{\text{SPICS}}$ pins to be deasserted between any two buffer transfers; otherwise, the Slave SPI will be unable to respond to the next data transfer.

NOTE: In compatibility mode, the slave does not require the $\overline{\text{SPICS}}$ pin to be deasserted between two buffer transfers. The CSHOLD bit of the slave will be ignored in compatibility mode.

28.2.6.6 Parallel Mode (Multiple SIMO/SOMI Support, not available on all devices)

In order to increase throughput, the parallel mode of the SPI enables the module to send data over more than one data line (parallel 2, 4, or 8). When parallel mode is used, the data length must be set as 16 bits. Only module MIBSPIP5 supports Parallel Mode.

This feature increases throughput by 2 for 2 pins, by 4 for 4 pins, or by 8 for 8 pins.

Parallel mode supports the following features:

- Scalable data lines (1, 2, 4, 8) per direction. (SOMI and SIMO lines)
- All clock schemes are supported (clock phase and polarity)
- Parity is supported. The parity bit will be transmitted on bit0 of the SIMO/SOMI lines. The receive parity is expected on bit0 of the SOMI/SIMO pins.

Parallel mode can be programmed using the PMODEx bits of SPIPMCTRL register. See Section 28.3.25 for details about this register.

After reset the parallel mode selection bits are cleared (single SIMO/SOMI lines).

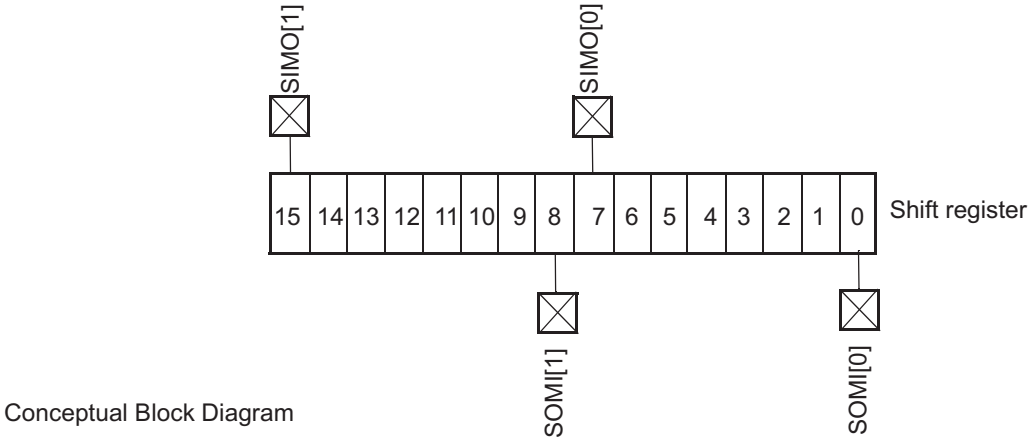
28.2.6.6.4 2-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 2-data line mode (master mode) the shift register bits 15 and 7 will be connected to the pins SIMO[1] and SIMO[0], and the shift register bits 8 and 0 will be connected to the pins SOMI[1] and SOMI[0] or vice versa in slave mode. After writing to the SPIDAT0/SPIDAT1 register, the bits 15 and 7 will be output on SIMO[1] and SIMO[0] on the rising edge if SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[1] and SOMI[0] will be latched to the shift register bits 8 and 0. The subsequent rising edge of SPICLK will shift the data in the shift register by 1 bit to the left. (SIMO[1] will shift the data out from bit 15 to 8, SIMO[0] will shift the data out from bit 7 to 0). After eight SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. Figure 28-24 shows the clock /data diagram of the 2-data line mode. Figure 28-25 shows the timing of a two-pin parallel transfer.

Figure 28-24. 2-data Line Mode (Phase 0, Polarity 0)



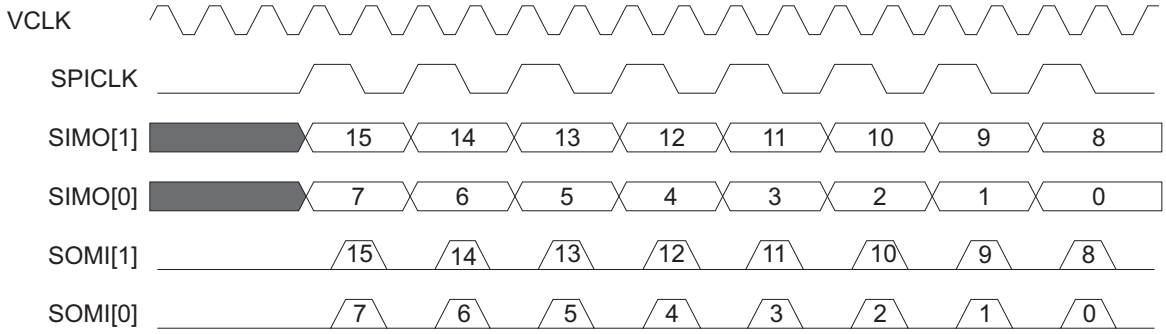


Figure 28-25. Two-Pin Parallel Mode Timing Diagram (Phase 0, Polarity 0)

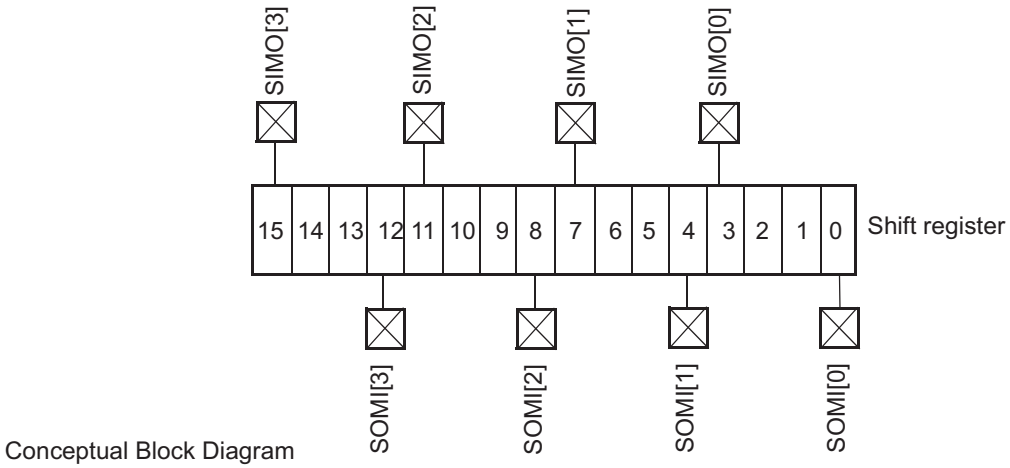
Copyright © 2018, Texas Instruments Incorporated

28.2.6.6.5 4-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 4-data line mode (master mode) the shift register bits 15, 11, 7, and 3 will be connected to the pins SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift register bits 12, 8, 4, and 0 will be connected to the pins SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode). After writing to SPIDAT1/SPIDAT0, the bits 15, 11, 7, and 3 will be output on SIMO[3], SIMO[2], SIMO[1], and SIMO[0] on the rising edge of SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[3], SOMI[2], SOMI[1] and SOMI[0] will be latched to shift register bits 12, 8, 4, and 0. The subsequent rising edge of SPICLK will shift data in the shift register by 1 bit to the left (SIMO[3] will shift the data out from bit 15 to 12, SIMO[2] will shift the data out from bit 11 to 8, SIMO[1] will shift the data out from bit 7 to 4, SIMO[0] will shift the data out from bit 3 to 0). After four SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set.

Figure 28-26 shows the clock/data diagram of the four-data line mode. Figure 28-27, shows the timing diagram for four-data line mode.

Figure 28-26. 4-Data Line Mode (Phase 0, Polarity 0)



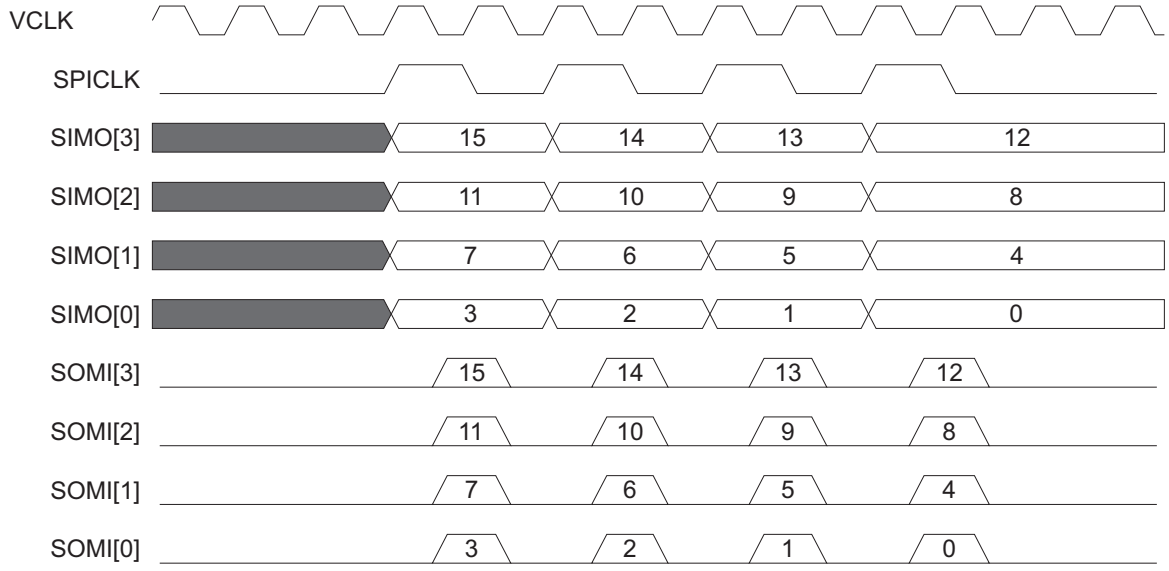


Figure 28-27. 4 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)

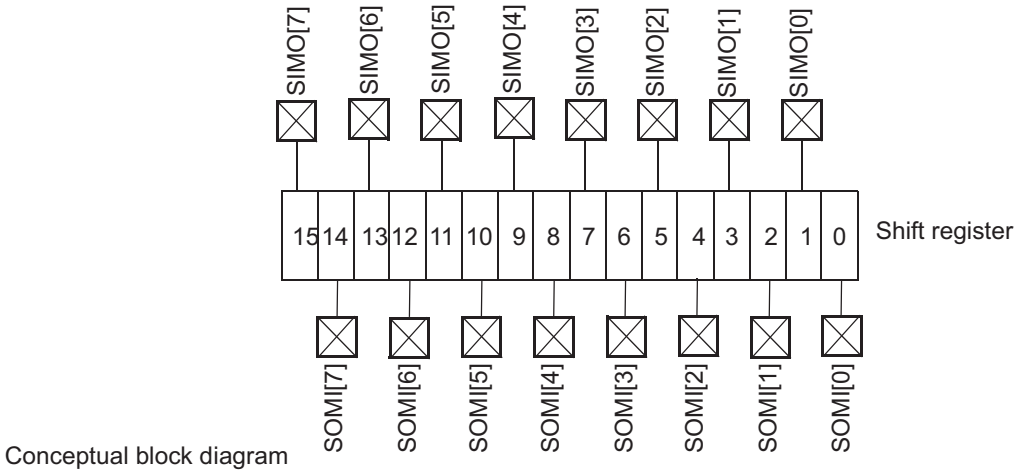
Copyright © 2018, Texas Instruments Incorporated



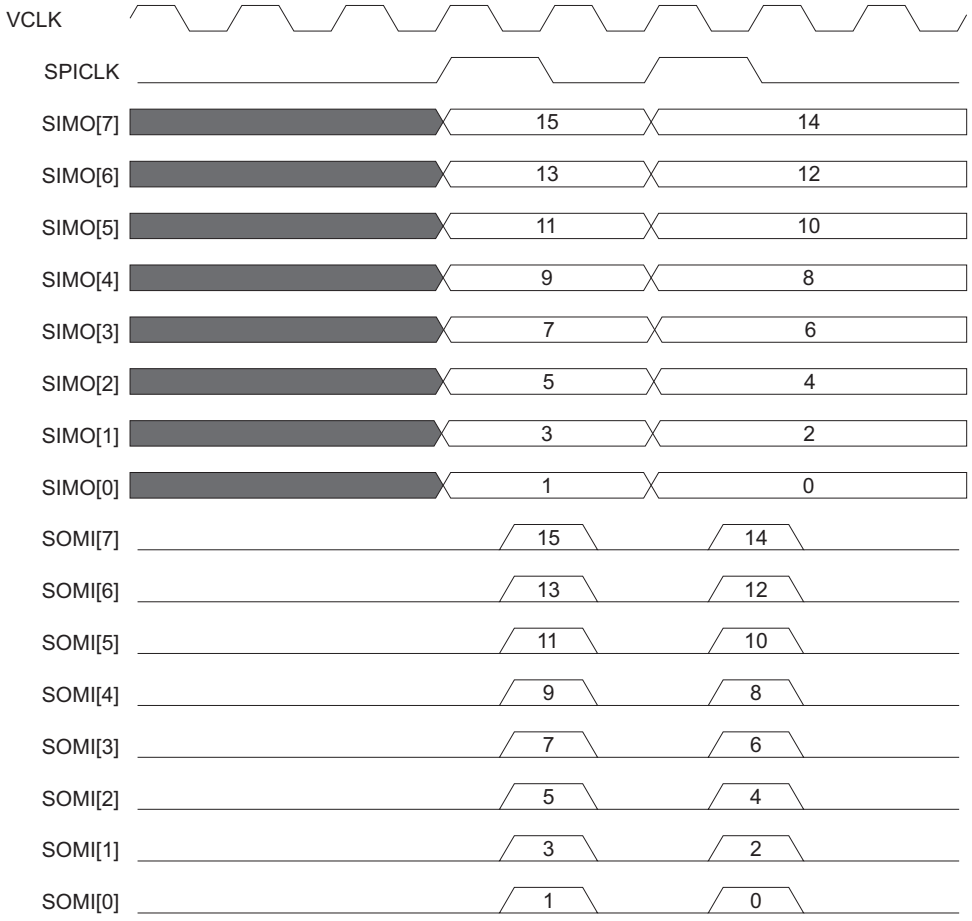
28.2.6.6.6 8-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 8-data line mode (master mode) the shift register bits 15, 13, 11, 9, 7, 5 and 3 will be connected to the pins SIMO[7], SIMO[6], SIMO[5], SIMO[4], SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift-register bits 14, 12, 10, 8, 6, 4, and 0 will be connected to the pins SOMI[7], SOMI[6], SOMI[5], SOMI[4], SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode).

After writing to SPIDAT0/SPIDAT1, the bits 15, 13, 11, 9, 7, 5, 3, and 1 will be output on SIMO[7], SIMO[6], SIMO[5], SIMO[4], SIMO[3], SIMO[2], SIMO[1], and SIMO[0], on the rising edge of SPICLK. On the falling clock edge of the SPICLK, the received data on SOMI[8], SOMI[7], SOMI[6],SOMI[5], SOMI[4], SOMI[3], SOMI[2], SOMI[1], and SOMI[0] will be latched to the shift register bits 14, 12, 10, 8, 6, 4, 2, and 0.

The subsequent rising edge of SPICLK will shift the data in the shift register by 1 bit to the left. After two SPICLK cycles, when the full data word is transferred the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. Figure 28-28 shows the clock/data diagram of the 8-data line mode. Figure 28-29 shows the pin timings for 8-data line mode.

Figure 28-28. 8-data Line Mode (Phase 0, Polarity 0)



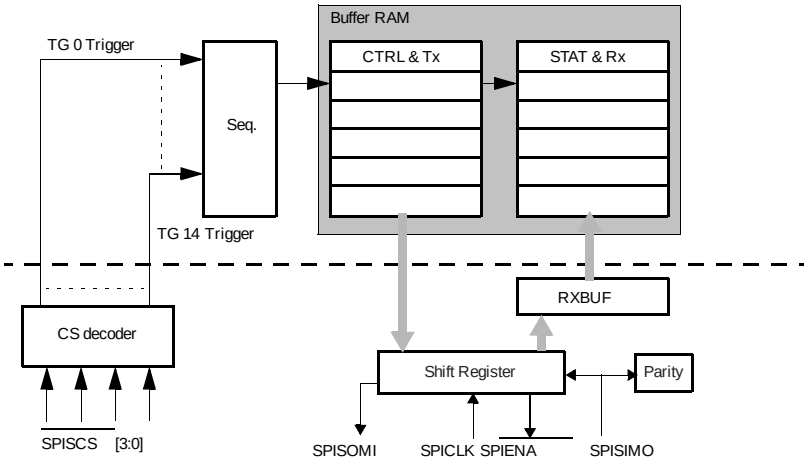
NOTE: Parity Support

Using the parity support in parallel mode may seriously affect throughput. For an eight-line mode to transfer 16 bits of data, only two SPICLK pulses are enough. If parity is enabled, one extra SPICLK pulse will be used to transfer and receive the parity bit. Parity will be transmitted and received on the 0th line regardless of 1/2/4/8-line modes. During the parity bit transfer, other data bits are not valid.

Copyright © 2018, Texas Instruments Incorporated

Figure 28-29. 8 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)

NOTE: Modulo Count Parallel Mode is not supported in this device.



28.2.6.7 MibSPI Slave in Multi-buffer Configuration

When operating in slave mode, the MibSPI uses the chip-select pins 0 to 3 to generate a trigger to the corresponding Transfer Group. For example, putting 0000 on the chip-select pins triggers Transfer Groups 0 and putting 0001 triggers TG1. When the value 1111 is set to the chip-select, the MibSPI is deselected, that is Transfer Group 15 is not available in slave mode. The remaining chip-select pins should stay in GPIO mode. In slave mode, the fields like trigger source and trigger event are not taken into account by the sequencer. Only the $\overline{\text{SPICS}}$ pins can trigger a Transfer Group. The chip-select trigger operates as a level-sensitive trigger. However, when the MibSPI is in 3-pin or 4-pin with $\overline{\text{SPIENA}}$ mode, just one Transfer Group can be triggered and it is restricted to Transfer Group 0 (TG0). In slave mode, the PRST field should be cleared to 0. If the corresponding Transfer Group is enabled, the multi-buffer reads the current buffer of the TG and writes it into SPIDAT1. If Transfer Group is disabled, the multi-buffer does not update the SPIDAT1 register.

NOTE: If the selected Transfer Group is disabled and no update of the SPIDAT1 register has been done, the data to be transferred is meaningless. Even the received data will not be copied to the multi-buffer RAM. However it will be available on SPIBUF register until it is overwritten by the subsequent receive data.

Copyright © 2018, Texas Instruments Incorporated

Figure 28-30. Multi-buffer in Slave Mode

When the SPIDAT1 register is updated, the enable signal is released, and the transaction could begin. If the enable signal is not used, the master should wait for 6 VCLK cycles before sending the clock to begin the transaction. This time allows the MibSPI to update the SPIDAT1 register.

Once the transaction is finished, the MibSPI writes back the content of the shift-register into the Rx buffer and updates the status field.

NOTE: If all the Transfer Groups are not needed, the number of $\overline{\text{SPICS}}$ pins that need to be in functional mode could be reduced to 3, 2, or 1 by using the SPIPC0 register. In these cases, the maximum number of Transfer Group accessible are, respectively 7, 3, and 1. The pins that are set in GPIO mode are not decoded.

MibSPI in 3-pin and 4-pin (with $\overline{\text{SPIENA}}$) mode also supports multi-buffer mode. However, it is restricted to having just one transfer group, Transfer Group 0 (TG0). The entire multi-buffer RAM can be configured for TG0 alone. The PSTART field in TG1CTRL register should be used to configure the size of the multi-buffer (end of the buffers) for TG0.

NOTE: The maximum input frequency on the SPICLK pin when in slave mode is VCLK frequency /2. If the Slave is configured in either 3-pin or 4-pin (without $\overline{\text{SPIENA}}$) modes, then, between end of last SPICLK and the start of SPICLK for next buffer, there should be at least 6 VCLK cycles of delay.

Copyright © 2018, Texas Instruments Incorporated

28.2.6.8 Transfer Groups

The size of the multi-buffer RAM depends on the implementation. It comprises 0 to 128/256 buffers, whereas 0 buffers considers the special case of no multi-buffer RAM. Each entry in the multi-buffer RAM consists of 4 parts: a 16-bit transmit field, a 16-bit receive field, a 16-bit control field and a 16-bit status field. The multi-buffer RAM can be partitioned into multiple transfer group with variable number of buffers each.

28.2.6.8.1 Configuring Transfer Groups and Trigger Events

Each TG can be configured via one dedicated control register, TGxCTRL. This register even configures the trigger events for the transfer group. The register is described in Section 28.3.34. The actual number of available control registers varies by device.

28.2.6.8.2 Sequencer-Which Handled the Sequencing of Triggered Transfer Groups

Sequencer(FSM) controls the data flow from the multi-buffer RAM to the Shift Register. The Multi-buffer Control Logic has arbitration logic between VBUS and the Sequencer accessing the multi-buffer RAM. Sequencer picks up a highest priority Transfer Group from among the active TGs to be serviced. For the selected TG the starting buffer to be transferred is obtained from the PSTART of the respective TGxCTRL register.

Sequencer requests for the selected buffer through the Multi-buffer Control Logic, and once it receives the data, it reads the control fields to determine the subsequent action. Once the buffer is determined to be ready for transfer, the data is written to the TX SHIFT REGISTER by the Sequencer. This triggers the Kernel FSM to initiate the SPI transfer.

28.2.6.8.3 Inter-group Prioritization and Arbitration

Transfer Group0 (TG0) has the highest priority and TG15 has the lowest priority among the transfer groups TG0 to TG15.Where as under the following conditions under the following conditions a lower priority Transfer Group cannot be interrupted by a higher priority TG.

- When there's a CSHOLD or LOCK buffer, until the completion of the next buffer transfer which is a non-CSHOLD or non-LOCK buffer, the Transfer Group cannot be interrupted by any higher priority TGs.
- An entire sequence of buffer transfer for NOBRK DMA buffer cannot be interrupted by any higher priority TG.
- Once the last buffer in a Transfer Group is prefetched, a higher priority TG cannot interrupt it until the completion of the Transfer Group.

These prioritizations made among the transfer groups also decide the arbitration logic among the multiple transfer groups which are active

28.2.6.8.4 Transmission Lock Capability

Some slave devices require to have "command" followed by "data". In this case the SPI transaction should not be interrupted by another group transfer. The LOCK bit within each buffer allows consecutive transfer to happen without being interrupted by another higher priority group transfer.

Copyright © 2018, Texas Instruments Incorporated

28.2.7 General-Purpose I/O

All of the SPI pins may be programmed via the SPIPCx control registers to be either functional or general-purpose I/O pins.

If the SPI function is to be used, application software must ensure that at least the SPICLK pin and the SOMI and/or SIMO pins are configured as SPI functional pins, and not as GIO pins, or else the SPI state machine will be held in reset, preventing SPI transactions.

SPI pins support:

- internal pull-up resistors
- internal pull-down resistors
- open-drain or push-pull mode
- input-buffer enabling/disabling (controlled by the PULDIS and PSEL bits)

28.2.8 Low-Power Mode

The SPI can be put into either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SPI. During global low-power mode, all clocks to the SPI are turned off, making the module completely inactive.

Local low-power mode is asserted by setting the POWERDOWN (SPIGCR1[8]) bit; setting this bit stops the clocks to the SPI internal logic and registers. Setting the POWERDOWN bit causes the SPI to enter local low-power mode and clearing the POWERDOWN bit causes SPI to exit from local low-power mode. All registers remain accessible during local power-down mode, since the clock to the SPI registers is temporarily re-enabled for each access. RAM buffers are also accessible during low power mode.

NOTE: Since entering a low-power mode has the effect of suspending all state-machine activities, care must be taken when entering such modes to ensure that a valid state is entered when low-power mode is active. Application software must ensure that a low power mode is not entered during a data transfer.

28.2.9 Safety Features

28.2.9.1 Detection of Slave Desynchronization (Master Only)

When a slave supports generation of an enable signal (ENA), desynchronization can be detected. With the enable signal a slave indicates to the master that it is ready to exchange data. A desynchronization can occur if one or more clock edges are missed by the slave. In this case the slave may block the SOMI line until it detects clock edges corresponding to the next data word. This would corrupt the data word of the desynchronized slave and the consecutive data word. A configurable 8-bit time-out counter (T2EDELAY), which is clocked with SPICLK, is implemented to detect this slave malfunction. After the transmission has finished (end of last bit transferred: either last data bit or parity bit) the counter is started. If the ENA signal generated by the slave does not become inactive before the counter overflows, the DESYNC flag is set and an interrupt is asserted (if enabled).

NOTE: Inconsistency of Desynchronization Flag in Compatibility Mode MibSPI

Because of the nature of this error, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is due to the fact that receive completion flag/interrupt will be generated when the buffer transfer is completed. But desync will be detected after the buffer transfer is completed. So, if VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desynchronization condition. This inconsistency in the desync flag is valid only in compatibility mode of MibSPI. In multi-buffer mode, the desync flag is always assured to be for the current buffer.

Copyright © 2018, Texas Instruments Incorporated

28.2.9.2 ENA Signal Time-Out (Master Only)

The SPI in master mode waits for the hardware handshake signal (ENA) coming from the addressed slave before performing a data transfer. To avoid stalling the SPI by a non-responsive slave device, a time-out value can be configured using C2EDELAY. If the time-out counter overflows before an active ENA signal is sampled, the TIMEOUT flag in the status register SPIFLG is set and the TIMEOUT flag in the status field of the corresponding buffer is set.

NOTE: When the chip select signal becomes active, no breaks in transmission are allowed. The next arbitration is performed while waiting for the time-out to occur.

28.2.9.3 Data-Length Error

An SPI can generate an error flag by detecting any mismatch in length of received or transmitted data and the programmed character length under certain conditions.

Data-Length Error in Master Mode: During a data transfer, if the SPI detects a de-assertion of the $\overline{\text{SPIENA}}$ pin (by the slave) while the character counter is not overflowed, then an error flag is set to indicate a data-length error. This can be caused by a slave receiving extra clocks (for example, due to noise on the SPICLK line).

NOTE: In a master mode SPI, the data length error will be generated only if the $\overline{\text{SPIENA}}$ pin is enabled as a functional pin.

Data-Length Error in Slave Mode: During a transfer, if the SPI detects a de-assertion of the $\overline{\text{SPICS}}$ pin before its character length counter overflows, then an error flag is set to indicate a data-length error. This situation can arise If the slave SPI misses one or more SPICLK pulses from the master. This error in slave mode implies that both the transmitted and received data were not complete.

NOTE: In a slave-mode SPI, the data-length error flag will be generated only if at least one of the $\overline{\text{SPICS}}$ pins are configured as functional, and are being used for selecting the slave.

28.2.9.4 Continuous Self-Test (Master/Slave)

During data transfer, the SPI compares its own internal transmit data with its transmit data on the bus. The sample point for the compare is at one-half SPI clock after transmit point. If the data on the bus does not match the expected value, the bit-error (BITERR) flag is set and an interrupt is asserted if enabled.

NOTE: The compare is made from the output pin using its input buffer.

Copyright © 2018, Texas Instruments Incorporated

28.2.10 Test Features

28.2.10.1 Internal Loop-Back Test Mode (Master Only)

The internal loop-back self-test mode can be utilized to test the SPI transmit and receive paths, including the shift registers, the SPI buffer registers, and the parity generator. In this mode the transmit signal is internally feedback to the receiver, whereas the SIMO, SOMI, and CLK pin are disconnected; that is, the transmitted data is internally transferred to the corresponding receive buffer while external signals remain unchanged.

This mode allows the CPU to write into the transmit buffer, and check that the receive buffer contains the correct transmit data. If an error occurs the corresponding error is set within the status field.

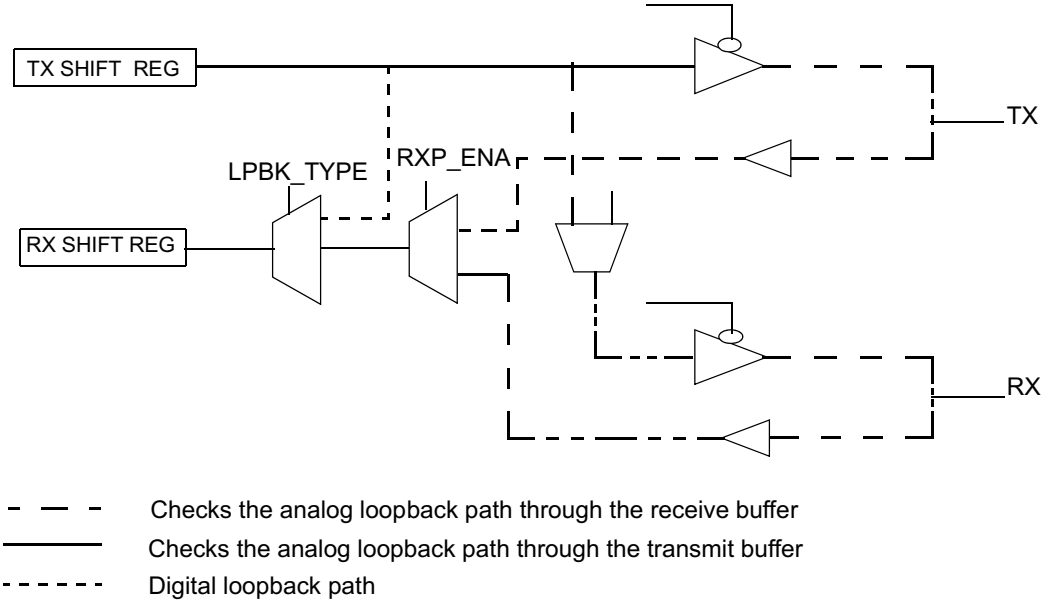
NOTE: This mode cannot be changed during transmission.

28.2.10.2 Input/Output Loopback Test Mode

Input/Output Loopback Test mode supports the testing of all Input/Output pins without the aid of an external interface. Loopback can be configured as either analog-loopback (loopback through the pin-level input/output buffers) or digital loopback (internal to the SPI module). With Input/Output Loopback, all functional features of the SPI can be tested. Transmit data is fed back through the receive-data line(s). See Figure 28-31 for a diagram of the types of feedback available. The IOLPBKTSTCR register defines all of the available control fields.

In loopback mode, it is also possible to induce various error conditions. See Section 28.3.43 for details of the register field controlling these features.

In Input/Output loopback test modes, even when the module is in slave mode, the SPICLK is generated internally. This SPICLK is used for all loopback-mode SPI transactions. Slave-mode features can be tested without the help of another master SPI, using the internally-generated SPICLK. Chip selects are also generated by the slave itself while it is in Input/Output loopback mode.



In Input/Output loopback test modes, if the module is in master mode, the $\overline{\text{ENA}}$ signal is also generated by internal logic so that an external interface is not required.

NOTE: Usage Guideline for Input/Output Loopback

Input/Output Loopback mode should be used with caution because, in some configurations, even the receive pins will be driven with transmit data. During testing, it should be ensured that none of the SPI pins are driven by any other device connected to them. Otherwise, if analog loopback is selected in I/O Loopback mode, then testing may damage the device.

Copyright © 2018, Texas Instruments Incorporated

Figure 28-31. I/O Paths During I/O Loopback Modes

This diagram is intended to illustrate loopback paths and therefore may omit some normal-mode paths.

28.2.10.2.1 Input/Output Loopback Mode Operation in Slave Mode

In multi-buffer slave mode, there are some additional requirements for using I/O loopback mode (IOLPBK). In multi-buffer slave mode, the chip-select pins are the triggers for various TGs. Enabling the IOLPBK mode by writing 0xA to the IOLPBTSTENA bits of the IOLPBKTSTCR register triggers TG0 by driving $\overline{\text{SPICS}}$ to 0. The actual number of chip selects can be programmed to have any or all of the $\overline{\text{SPICS}}$ pins as functional. All other configurations should be completed before enabling the IOLPBK mode in multi-buffer slave mode since it triggers TG0.

After the first buffer transfer is completed, the CSNR field of the current buffer is used to trigger the next buffer. So, if multiple TGs are desired to be tested, then the CSNR field of the final buffer in each TG should hold the number of the next TG to be triggered. As long as TG boundaries are well defined and are enabled, the completion of one TG will trigger the next TG.

To stop the transfer in multi-buffer slave mode in I/O Loopback configuration, either IOLPBK mode can be disabled by writing 0x5 to the IOLPBTSTENA bits or all of the TGs can be disabled.

28.2.11 Module Configuration

MibSPI/MibSPIP can be configured to function as Normal SPI and Multi-buffered SPI. Upon power-up or a system-level reset, each bit in the module registers is set to a default state. The registers are writable only after the RESET bit is set to 1.

28.2.11.1 Compatibility (SPI) Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SPIEN bit in the Global Control Register 1 (SPIGCR1) is cleared to 0 the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Configure the SIMO, SOMI, CLK, and optional $\overline{\text{SPICS}}$ and $\overline{\text{SPIENA}}$ pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Enable the Interrupts using SPIINT0 register if required.
- Select the chip select to be used by setting CSNR bits in SPIDAT1 register.
- Configure CSHOLD and WDEL bits in SPIDAT1 register if required.
- Select the Data word format by setting DFSEL bits. Select the Number of the configured SPIFMTx register (0 to 3) to used for the communication.
- Set LOOPBACK bit to connect the transmitter to the receiver internally. (This feature is used to perform a self-test. Do not configure for normal communication to external devices).
- Set SPIEN bit to 1 after the SPI is configured.
- Perform Transmit and receive data, using SPIDAT1 and SPIBUF register.
- You must wait for TXFULL to reset or TXINT before writing next data to SPIDAT1 register.
- You must wait for RXEMPTY to reset or RXINT before reading the data from SPIBUF register.

Copyright © 2018, Texas Instruments Incorporated

28.2.11.2 MibSPI Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data in MIBSPI mode. As long as the SPIEN bit in the Global Control Register 1 (SPIGCR1) is cleared to 0 the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Set MSPIENA bit to 1 to get access to multi-buffer mode registers.
- Configure the SIMO, SOMI, CLK, and optional $\overline{\text{SPICS}}$ and $\overline{\text{SPIENA}}$ pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Check for BUFINITACTIVE bit to be active before configuring MIBSPI RAM. (From Device Power On it take Number of Buffers × Peripheral clock period to initialize complete RAM.)
- Enable the Transfer Group interrupts using TGITENST register if required.
- Enable error interrupts using SPIINT0 register if required.
- Set SPIEN bit to 1 after the SPI is configured.
- The Trigger Source, Trigger Event, Transfer Group start address for the corresponding Transfer groups can be configured using the corresponding TGxCTRL register.
- Configure LPEND to specify the end address of the last TG.
- Similar to SPIDAT1 register, the 16 bit control fields in every TXRAM buffer in the TG have to be configured.
- Configure one of the eight BUFMODE available for each buffer.
- Fill the data to be transmitted in TXDATA field in TXRAM buffers.
- Configure TGENA bit to enable the required Transfer groups. (In case of Trigger event always setting TGENA will trigger the transfer group).
- At the occurrence of the correct trigger event, the Transfer group will be triggered and data gets transmitted and received one after the other with out any CPU intervention.
- You can poll Transfer group interrupt flag or wait for a transfer-completed interrupt to read and write new data to the buffers.

28.3 Control Registers

This section describes the SPI control, data, and pin registers. The registers support 8-bit, 16-bit and 32-bit writes. The offset is relative to the associated base address of this module in a system. The base address for the control registers is FFF7 F400h for MibSPI1, FFF7 F600h for MibSPI2, FFF7 F800h for MibSPI3, FFF7 FA00h for MibSPI4, and FFF7 FC00h for MibSPI5.

NOTE: TI highly recommends that write values corresponding to the reserved locations of registers be maintained as 0 consistently. This allows future enhancements to use these reserved bits as control bits without affecting the functionality of the module with any older versions of software.

Table 28-9. SPI Global Control Register 0 (SPIGCR0) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reads return 0. Writes have no effect.
0	nRESET		This is the local reset control for the module. This bit needs to be set to 1 before any operation on SPI / MibSPI can be done. Only after setting this bit to 1, the Auto Initialization of Multi-buffer RAM starts. Clearing this bit to 0 will result in all of the control and status register values to return to their default values..
		0	SPI is in the reset state.
		1	SPI is out of the reset state.

Table 28-10. SPI Global Control Register 1 (SPIGCR1) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	SPIEN		SPI enable. This bit enables SPI transfers. This bit must be set to 1 after all other SPI configuration bits have been written. When the SPIEN bit is 0 or cleared to 0, the following SPI registers get forced to their default states: • Both TX and RX shift registers • The TXDATA fields of the SPI Transmit Data Register 0 (SPIDAT0) and the SPI Transmit Data Register 1 (SPIDAT1) • All the fields of the SPI Flag Register (SPIFLG) • Contents of SPIBUF and the internal RXBUF registers
		0	The SPI is not activated for transfers.
		1	Activates SPI.
23-17	Reserved	0	Reads return 0. Writes have no effect.
16	LOOPBACK		Internal loop-back test mode. The internal self-test option can be enabled by setting this bit. If the SPISIMO and SPISOMI pins are configured with SPI functionality, then the SPISIMO[7:0] pins are internally connected to the SPISOMI[7:0] pins (transmit data is looped back as receive data). GIO mode for these pins is not supported in loopback mode. Externally, during loop-back operation, the SPICLK pin outputs an inactive value and SPISOMI[7:0] remains in the high-impedance state. If the SPI is initialized in slave mode or a data transfer is ongoing, errors may result. **Note: This loopback mode can only be used in master mode. Master mode must be selected before setting LOOPBACK. When this mode is selected, the CLKMOD bit should be set to 1, meaning that SPICLK is internally generated.**
		0	Internal loop-back test mode is disabled.
		1	Internal loop-back test mode is enabled.
15-9	Reserved	0	Reads return 0. Writes have no effect.
8	POWERDOWN		When active, the SPI state machine enters a power-down state.
		0	The SPI is in active mode.
		1	The SPI is in power-down mode.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	CLKMOD		Clock mode. This bit selects either an internal or external clock source. This bit also determines the I/O direction of the $\overline{\text{SPIENA}}$ and $\overline{\text{SPICS}}$ pins in functional mode.
		0	Clock is external. • $\overline{\text{SPIENA}}$ is an output. • $\overline{\text{SPICS}}$ are inputs.
		1	Clock is internally-generated. • $\overline{\text{SPIENA}}$ is an input. • $\overline{\text{SPICS}}$ are outputs.

Copyright © 2018, Texas Instruments Incorporated

Table 28-10. SPI Global Control Register 1 (SPIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
0	MASTER		SPISIMO/SPISOMI pin direction determination. Sets the direction of the SPISIMO and SPISOMI pins.
			Note: For master-mode operation of the SPI, MASTER bit should be set to 1 and CLKMOD bit can be set either 1 or 0. The master-mode SPI can run on an external clock on SPICLK.
			For slave mode operation, both the MASTER and CLKMOD bits should be cleared to 0. Any other combinations may result in unpredictable behavior of the SPI. In slave mode. SPICLK will not be generated internally in slave mode.
		0	SPISIMO[7:0] pins are inputs, SPISOMI[7:0] pins are outputs.
		1	SPISOMI[7:0] pins are inputs, SPISIMO[7:0] pins are outputs.

28.3.3 SPI Interrupt Register (SPIINT0)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 28-11. SPI Interrupt Register (SPIINT0) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	ENABLEHIGHZ		$\overline{\text{SPIENA}}$ pin high-impedance enable. When active, the $\overline{\text{SPIENA}}$ pin (when it is configured as a WAIT functional output signal in a slave SPI) is forced to high-impedance when not driving a low signal. If inactive, then the pin will output both a high and a low signal.
		0	$\overline{\text{SPIENA}}$ pin is pulled high when not active.
		1	$\overline{\text{SPIENA}}$ pin remains high-impedance when not active.
23-17	Reserved	0	Reads return 0. Writes have no effect.
16	DMAREQEN		DMA request enable. Enables the DMA request signal to be generated for both receive and transmit channels. Enable DMA REQ only after setting the SPIEN bit to 1.
		0	DMA is not used.
		1	DMA requests will be generated.
			Note: A DMA request will be generated on the TX DMA REQ line each time a word is copied to the shift register either from TXBUF or directly from SPIDAT0/SPIDAT1 writes.
			Note: A DMA request will be generated on the RX DMA REQ line each time a word is copied to the SPIBUF register either from RXBUF or directly from the shift register.
15-10	Reserved	0	Reads return 0. Writes have no effect.

Copyright © 2018, Texas Instruments Incorporated

Table 28-11. SPI Interrupt Register (SPIINT0) Field Descriptions (continued)

Bit	Field	Value	Description
9	TXINTENA		Causes an interrupt to be generated every time data is written to the shift register, so that the next word can be written to TXBUF. Setting this bit will generate an interrupt if the TXINTFLG bit (SPI Flag Register (SPIFLG)[9]) is set to 1.
		0	No interrupt will be generated upon TXINTFLG being set to 1.
		1	An interrupt will be generated upon TXINTFLG being set to 1.
			The transmitter empty interrupt is valid in compatibility mode of SPI only. In multi-buffered mode, this interrupts will not be generated, even if it is enabled.
			Note: An interrupt request will be generated as soon as this bit is set to 1. By default it will be generated on the INT0 line. The SPILVL register can be programmed to change the interrupt line.
8	RXINTENA		Causes an interrupt to be generated when the RXINTFLAG bit (SPI Flag Register (SPIFLG)[8]) is set by hardware.
		0	Interrupt will not be generated.
		1	Interrupt will be generated.
			The receiver full interrupt is valid in compatibility mode of SPI only. In multi-buffered mode, this interrupts will not be generated, even if it is enabled.
7	Reserved	0	Reads return 0. Writes have no effect.
6	RXOVRNINTENA		Overrun interrupt enable.
		0	Overrun interrupt will not be generated.
		1	Overrun interrupt will be generated.
5	Reserved	0	Reads return 0. Writes have no effect.
4	BITERRENA		Enables interrupt on bit error.
		0	No interrupt asserted upon bit error.
		1	Enables interrupt on bit error.
3	DESYNCENA		Enables interrupt on desynchronized slave. DESYNCENA is used in master mode only.
		0	No interrupt asserted upon desynchronization error.
		1	An interrupt is asserted on desynchronization of the slave (DESYNC = 1).
2	PARERRENA		Enables interrupt-on-parity-error.
		0	No interrupt asserted on parity error.
		1	An interrupt is asserted on a parity error.
1	TIMEOUTENA		Enables interrupt on ENA signal time-out.
		0	No interrupt asserted upon ENA signal time-out.
		1	An interrupt is asserted on a time-out of the ENA signal.
0	DLENERRENA		Data length error interrupt enable. A data length error occurs under the following conditions.
			Master: When $\overline{\text{SPIENA}}$ is used, if the $\overline{\text{SPIENA}}$ pin from the slave is deasserted before the master has completed its transfer, the data length error is set. That is, if the character length counter has not overflowed while $\overline{\text{SPIENA}}$ deassertion is detected, then it means that the slave has neither received full data from the master nor has it transmitted complete data.
			Slave: When $\overline{\text{SPICS}}$ pins are used, if the incoming valid $\overline{\text{SPICS}}$ pin is deactivated before the character length counter overflows, then the data length error is set.
		0	No interrupt is generated upon data length error.
		1	An interrupt is asserted when a data-length error occurs.

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 28-13. SPI Flag Register (SPIFLG) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	BUFINITACTIVE		Indicates the status of multi-buffer initialization process. Software can poll for this bit to determine if it can proceed with the register configuration of multi-buffer mode registers or buffer handling. **Note: If the SPIFLG register is read while the multi-buffer RAM is being initialized, the BUF INIT ACTIVE bit will be read as 1. If SPIFLG is read after the internal automatic buffer initialization is complete, this bit will be read as 0. This bit will show a value of 1 as long as the nRESET bit is 0, but does not really indicate that buffer initialization is underway. Buffer initialization starts only when the nRESET bit is set to 1.**
		0	Multi-buffer RAM initialization is complete.
		1	Multi-buffer RAM is still being initialized. Do not attempt to write to either multi-buffer RAM or any multi-buffer mode registers.
23-10	Reserved	0	Reads return 0. Writes have no effect.
9	TXINTFLG		Transmitter-empty interrupt flag. Serves as an interrupt flag indicating that the transmit buffer (TXBUF) is empty and a new word can be written to it. This flag is set when a word is copied to the shift register either directly from SPIDAT0/SPIDAT1 or from the TXBUF register. This bit is cleared by one of following methods: • Writing a new data to either SPIDAT0 or SPIDAT1 • Writing a 0 to SPIEN (SPIGCR1[24])
		0	Transmit buffer is now full. No interrupt pending for transmitter empty.
		1	Transmit buffer is empty. An interrupt is pending to fill the transmitter.

Copyright © 2018, Texas Instruments Incorporated

Table 28-13. SPI Flag Register (SPIFLG) Field Descriptions (continued)

Bit	Field	Value	Description
8	RXINTFLG		Receiver-full interrupt flag. This flag is set when a word is received and copied into the buffer register (SPIBUF). If RXINTEN is enabled, an interrupt is also generated. This bit is cleared under the following methods: • Reading the SPIBUF register • Reading TGINTVECT0 or TGINTVECT1 register when there is a receive buffer full interrupt • Writing a 1 to this bit • Writing a 0 to SPIEN (SPIGCR1[24]) • System reset During emulation mode, however, a read to the emulation register (SPIEMU) does not clear this flag bit.
		0	No new received data pending. Receive buffer is empty.
		1	A newly received data is ready to be read. Receive buffer is full.
			Note: Clearing RXINTFLG bit by writing a 1 before reading the SPIBUF sets the RXEMPTY bit of the SPIBUF register too. In this way, one can ignore a received word. However, if the internal RXBUF is already full, the data from RXBUF will be copied to SPIBUF and the RXEMPTY bit will be cleared again. The SPIBUF contents should be read first if this situation needs to be avoided.
7	Reserved	0	Reads return 0. Writes have no effect.
6	RXOVRNINTFLG		Receiver overrun flag. The SPI hardware sets this bit when a receive operation completes before the previous character has been read from the receive buffer. The bit indicates that the last received character has been overwritten and therefore lost. The SPI will generate an interrupt request if this bit is set and the RXOVRN INTEN bit (SPIINT0.6) is set high. This bit is cleared under the following conditions in compatibility mode of MibSPI: • Reading TGINTVECT0 or TGINTVECT1 register when there is a receive-buffer-overrun interrupt • Writing a 1 to RXOVRNINTFLG in the SPI Flag Register (SPIFLG) itself • Writing a 0 to SPIEN • Reading the data field of the SPIBUF register
			Note: Reading the SPIBUF register does not clear this RXOVRNINTFLG bit. If an RXOVRN interrupt is detected, then the SPIBUF may need to be read twice to get to the overrun buffer. This is due to the fact that the overrun will always occur to the internal RXBUF. Each read to the SPIBUF will result in RXBUF contents (if it is full) getting copied to SPIBUF.
			Note: There is a special condition under which the RXOVRNINTFLG flag gets set. If both SPIBUF and RXBUF are already full and while another reception is underway, if any errors (TIMEOUT, BITERR, and DLEN_ERR) occur, then RXOVR in RXBUF and RXOVRNINTFLG in SPIFLG registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a receive overrun.
			In multi-buffer mode of MibSPI, this bit is cleared under the following conditions: • Reading the RXOVRN_BUF_ADDR register • Writing a 1 to RXOVRNINTFLG in the SPI Flag Register (SPIFLG) itself In multi-buffer mode, if RXOVRNINTFLG is set, then the address of the buffer which experienced the overrun is available in RXOVRN_BUF_ADDR.
		0	Overrun condition did not occur.
		1	Overrun condition has occurred.
5	Reserved	0	Reads return 0. Writes have no effect.
4	BITERRFLG		Mismatch of internal transmit data and transmitted data. This flag can be cleared by one of the following methods: • Write a 1 to this bit. • Clear the SPIEN bit to 0.
		0	No bit error occurred.
		1	A bit error occurred. The SPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the flag BITERRFLG is set. If BITERRENA is set an interrupt is asserted. Possible reasons for a bit error can be an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.

Copyright © 2018, Texas Instruments Incorporated

Table 28-13. SPI Flag Register (SPIFLG) Field Descriptions (continued)

Bit	Field	Value	Description
3	DESYNCFLG		Desynchronization of slave device. Desynchronization monitor is active in master mode only. This flag can be cleared by one of the following methods: • Write a 1 to this bit. • Clear the SPIEN bit to 0.
		0	No slave desynchronization detected.
		1	A slave device is desynchronized. The master monitors the ENAble signal coming from the slave device and sets the DESYNC flag after the last bit is transmitted plus $t_{T2EDELAY}$. If DESYNCENA is set an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.
2	PARERRFLG		Calculated parity differs from received parity bit. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set and an interrupt is asserted if PARERRENA is set. This flag can be cleared by one of the following methods: • Write a 1 to this bit. • Clear the SPIEN bit to 0.
		0	No parity error detected.
		1	A parity error occurred.
1	TIMEOUTFLG		Time-out caused by nonactivation of ENA signal. This flag can be cleared by one of the following methods: • Write a 1 to this bit. • Clear the SPIEN bit to 0.
		0	No ENA-signal time-out occurred.
		1	An ENA signal time-out occurred. The SPI generates a time-out because the slave has not responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMEOUT flag in the status field of the corresponding buffer is set. The transmit request of the concerned buffer is cleared, that is, the SPI does not re-start a data transfer from this buffer.
0	DLENERRFLG		Data-length error flag. This flag can be cleared by one of the following methods: • Write a 1 to this bit. • Clear the SPIEN bit to 0. **Note: Whenever any transmission errors (TIMEOUT, BITERR, DLEN_ERR, PARITY_ERR, DESYNC) are detected and the error flags are cleared by writing to the error bit in the SPIFLG register, the corresponding error flag in SPIBUF does not get cleared. Software needs to read the SPIBUF until it becomes empty before proceeding. This ensures that all of the old status bits in SPIBUF are cleared before starting the next transfer.**
		0	No data length error has occurred.
		1	A data length error has occurred.

28.3.6 SPI Pin Control Register 0 (SPIPC0)

NOTE: Register bits vary by device

Register bits 31:24 and 23:16 of SPIPC0 to SPIPC9 reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Table 28-14. SPI Pin Control (SPIPC0) Field Descriptions

Bit	Field	Value	Description
31-24	SOMIFUN		Slave out, master in function. Determines whether SPISOMI[x] is to be used as a general-purpose I/O pin or as a SPI functional pin.
			Note: Duplicate Control Bits for SPISOMI[0]. Bit 24 is not physically implemented. It is a mirror of Bit 11. Any write to bit 24 will be reflected on bit 11. When bit 24 and bit 11 are simultaneously written, the value of bit 11 will control the SPISOMI[0] pin. The read value of Bit 24 always reflects the value of bit 11.
		0	SPISOMI[x] pin is a GIO pin.
		1	SPISOMI[x] pin is a SPI functional pin.
23-16	SIMOFUN		Slave in, master out function. Determines whether SPISIMO[x] is to be used as a general-purpose I/O pin or as a SPI functional pin.
			Note: Duplicate Control Bits for SPISIMO[x]. Bit 16 is not physically implemented. It is a mirror of Bit 10. Any write to bit 16 will be reflected on bit 10. When bit 16 and bit 10 are simultaneously written, the value of bit 10 will control the SPISOMI[x] pin. The read value of Bit 16 always reflects the value of bit 10.
		0	SPISIMOx pin is a GIO pin.
		1	SPISIMOx pin is a SPI functional pin.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	SOMIFUN0		Slave out, master in function. This bit determines whether the SPISOMI0 pin is to be used as a general-purpose I/O pin or as a SPI functional pin.
		0	SPISOMI0 pin is a GIO pin.
		1	SPISOMI0 pin is a SPI functional pin.
			Note: Regardless of the number of parallel pins used, the SPISOMI0 pin will always have to be programmed as functional pins for any SPI transfers.
10	SIMOFUN0		Slave in, master out function. This bits determine whether each SPISIMO0 pin is to be used as a general-purpose I/O pin or as a SPI functional pin.
		0	SPISIMO0 pin is a GIO pin.
		1	SPISIMO0 pin is a SPI functional pin.
			Note: Regardless of the number of parallel pins used, the SPISIMO0 pin will always have to be programmed as functional pins for any SPI transfers.

Table 28-14. SPI Pin Control (SPIPC0) Field Descriptions (continued)

Bit	Field	Value	Description
9	CLKFUN		SPI clock function. This bit determines whether the SPICLK pin is to be used as a general-purpose I/O pin, or as a SPI functional pin.
		0	SPICLK pin is a GIO pin.
		1	SPICLK pin is a SPI functional pin.
8	ENAFUN		$\overline{\text{SPIENA}}$ function. This bit determines whether the $\overline{\text{SPIENA}}$ pin is to be used as a general-purpose I/O pin or as a SPI functional pin.
		0	$\overline{\text{SPIENA}}$ pin is a GIO pin.
		1	$\overline{\text{SPIENA}}$ pin is a SPI functional pin.
7-0	SCSFUN		$\overline{\text{SPICS}}$ function. Determines whether each $\overline{\text{SPICS}}$ pin is to be used as a general-purpose I/O pin or as a SPI functional pin. If the slave $\overline{\text{SPICS}}$ pins are in functional mode and receive an inactive-high signal, the slave SPI will place its output in high-impedance and disable shifting.
		0	$\overline{\text{SPICS}}$ pin is a GIO pin.
		1	$\overline{\text{SPICS}}$ pin is a SPI functional pin.

28.3.7 SPI Pin Control Register 1 (SPIPC1)

NOTE: Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Table 28-15. SPI Pin Control Register (SPIPC1) Field Descriptions (continued)

Bit	Field	Value	Description
23-16	SIMODIR		SPISIMOx direction. Controls the direction of SPISIMOx when used for general-purpose I/O. If SPISIMOx pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register.
			Note: Duplicate Control Bits for SPISIMO. Bit 16 is not physically implemented. It is a mirror of Bit 10. Any write to bit 16 will be reflected on bit 10. When bit 16 and bit 10 are simultaneously written, the value of bit 10 will control the SPISOMI pin. The read value of Bit 16 always reflects the value of bit 10.
		0	SPISOMIOx pin is an input.
		1	SPISOMIOx pin is an output.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	SOMIDIR0		SPISOMI0 direction. This bit controls the direction of the SPISOMI0 pin when it is used as a general-purpose I/O pin. If the SPISOMI0 pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register.
		0	SPISOMI0 pin is an input.
		1	SPISOMI0 pin is an output.
10	SIMODIR0		SPISIMO0 direction. This bit controls the direction of the SPISIMO0 pin when it is used as a general-purpose I/O pin. If the SPISIMO0 pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register.
		0	SPISIMO0 pin is an input.
		1	SPISIMO0 pin is an output.
9	CLKDIR		SPICLK direction. This bit controls the direction of the SPICLK pin when it is used as a general-purpose I/O pin. In functional mode, the I/O direction is determined by the CLKMOD bit.
		0	SPICLK pin is an input.
		1	SPICLK pin is an output.
8	ENADIR		$\overline{\text{SPIENA}}$ direction. This bit controls the direction of the $\overline{\text{SPIENA}}$ pin when it is used as a general-purpose I/O. If the $\overline{\text{SPIENA}}$ pin is used as a functional pin, then the I/O direction is determined by the CLKMOD bit (SPIGCR1[1]).
		0	$\overline{\text{SPIENA}}$ pin is an input.
		1	$\overline{\text{SPIENA}}$ pin is an output.
7-0	SCSDIR		$\overline{\text{SPICS}}$ direction. These bits control the direction of each $\overline{\text{SPICS}}$ pin when it is used as a general-purpose I/O pin. Each pin could be configured independently from the others if the $\overline{\text{SPICS}}$ is used as a SPI functional pin. The I/O direction is determined by the CLKMOD bit (SPIGCR1[1]).
		0	$\overline{\text{SPICS}}$ pin is an input.
		1	$\overline{\text{SPICS}}$ pin is an output.

		1	Read: The current value on SCSDOUT is 1. Write: Logic 0 is placed on $\overline{\text{SPICS}}$ pin, if it is in general-purpose output mode.

28.3.12 SPI Pin Control Register 6 (SPIPC6)

NOTE: Register bits vary by device

Register bits 31:24 and 23:16 of SPIPC0 to SPIPC9 reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Table 28-20. SPI Pin Control Register 6 (SPIPC6) Field Descriptions

Bit	Field	Value	Description
31-24	SOMIPDR		SPISOMIx open drain enable. This bit enables open drain capability for the SPISOMIx pin if the following conditions are met: • SOMIDIRx = 1 (SPISOMIx pin configured in GIO mode as an output) • SOMIDOUTx = 1 **Bit 11 or bit 24 can both be used to enable open-drain for SOMI0. If a 32-bit write is performed, bit 11 will have priority over bit 24.**
		0	The output value on the SPISOMIx pin is logic 1.
		1	Output pin SPISOMIx is in a high-impedance state.
23-16	SIMOPDR		SPISIMOx open drain enable. This bit enables open drain capability for the SPISIMOx pin if the following conditions are met: • SIMODIRx = 1 (SPISIMOx pin configured in GIO mode as an output) • SIMODOUTx = 1 **Bit 10 or bit 16 can both be used to enable open-drain for SIMO0. If a 32-bit write is performed, bit 10 will have priority over bit 16.**
		0	The output value on SPISIMOx pin is logic 1.
		1	Output pin SPISIMOx is in a high-impedance state.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	SOMIPDR0		SOMI0 open-drain enable. This bit enables open-drain capability for SOMI0 if the following conditions are met. • SOMI0 pin configured in GIO mode as output pin • Output value on SPISOMI0 pin is logic 1.
		0	Output value 1 of SPISOMI0 pin is logic 1.
		1	Output value 1 of SPISOMI0 is high-impedance.
10	SIMOPDR0		SPISIMO0 open-drain enable. This bit enables open -drain capability for the SPISIMO0 pin if the following conditions are met. • SIMO0 pin configured in GIO mode as output pin • Output value on SPISIMO0 pin is logic 1.
		0	Output value 1 of SPISIMO0 pin is logic 1.
		1	Output value 1 of SPISIMO0 is high-impedance.
9	CLKPDR		CLK open drain enable. This bit enables open drain capability for the pin CLK if the following conditions are met: • SPICLK pin configured in GIO mode as an output pin • SPICLKDOUT = 1
		0	Output value on CLK pin is logic 1.
		1	Output pin CLK is in a high-impedance state.
8	ENAPDR		$\overline{\text{SPIENA}}$ open drain enable. This bit enables open drain capability for the $\overline{\text{SPIENA}}$ pin, if the following conditions are met: • $\overline{\text{SPIENA}}$ pin configured in GIO mode as an output pin • SPIENADOUT = 1
		0	Output value on the $\overline{\text{SPIENA}}$ pin is logic 1.
		1	Output pin $\overline{\text{SPIENA}}$ is in a high-impedance state.
7-0	SCSPDR		$\overline{\text{SPICS}}$ open drain enable. This bit enables open drain capability for the $\overline{\text{SPICS}}$ pin, if the following conditions are met: • $\overline{\text{SPICS}}$ pin configured in GIO mode as an output pin • SCSDOUT = 1
		0	Output value on the $\overline{\text{SPICS}}$ pin is logic 1.
		1	Output pin $\overline{\text{SPICS}}$ is in a high-impedance state.

Table 28-23. SPI Transmit Data Register 0 (SPIDAT0) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0. Writes have no effect.
15-0	TXDATA	0-FFFFh	SPI transmit data. When written, these bits will be copied to the shift register if it is empty. If the shift register is not empty, TXBUF holds the written data. SPIEN (SPICGR1[24]) must be set to 1 before this register can be written to. Writing a 0 to the SPIEN register forces the lower 16 bits of the SPIDAT0 to 0x00.
			Note: When this register is read, the contents TXBUF, which holds the latest written data, will be returned.
			Note: Regardless of character length, the transmit word should be right-justified before writing to the SPIDAT1 register.
			Note: The default data format control register for SPIDAT0 is SPIFMT0. However, it is possible to reprogram the DFSEL[1:0] fields of SPIDAT1 before using SPIDAT0, to select a different SPIFMTx register.
			Note: It is highly recommended to use SPIDAT1 register, SPIDAT0 is supported for compatibility reasons.

Copyright © 2018, Texas Instruments Incorporated

28.3.16 SPI Transmit Data Register 1 (SPIDAT1)

NOTE: Writing to only the control fields, bits 28 through 16, does not initiate any SPI transfer in master mode. This feature can be used to set up SPICLK phase or polarity before actually starting the transfer by only updating the DFSEL bit field to select the required phase and polarity combination.

Figure 28-47. SPI Transmit Data Register 1 (SPIDAT1) [offset = 3Ch]

15 0
TXDATA
R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 28-24. SPI Transmit Data Register 1 (SPIDAT1) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reads return 0. Writes have no effect.
28	CSHOLD		Chip select hold mode. The CSHOLD bit is supported in master mode only in compatibility-mode of SPI, (it is ignored in slave mode). CSHOLD defines the behavior of the chip select line at the end of a data transfer.
		0	The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.
		1	The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes.
27	Reserved	0	Reads return 0. Writes have no effect.
26	WDEL		Enable the delay counter at the end of the current transaction.
			Note: The WDEL bit is supported in master mode only. In slave mode, this bit will be ignored.
		0	No delay will be inserted. However, the $\overline{\text{SPICS}}$ pins will still be de-activated for at least for 2VCLK cycles if CSHOLD = 0.
			Note: The duration for which the $\overline{\text{SPICS}}$ pin remains deactivated depends upon the time taken to supply a new word after completing the shift operation. If TXBUF is already full, then the $\overline{\text{SPICS}}$ pin will be deasserted for at least two VCLK cycles (if WDEL = 0).
		1	After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The $\overline{\text{SPICS}}$ pins will be de-activated for at least (WDELAY + 2) × VCLK_Period duration.
25-24	DFSEL		Data word format select.
		0	Data word format 0 is selected.
		1h	Data word format 1 is selected.
		2h	Data word format 2 is selected.
		3h	Data word format 3 is selected.
23-16	CSNR	0-FFh	Chip select (CS) number. CSNR defines the chip select pins that will be activated during the data transfer. CSNR is a bit-mask that controls all chip select pins. See Table 28-25.
			Note: If your MibSPI has less than 8 chip select pins, all unused upper bits will be 0. For example, MiBSPI3 has 6 chip select pins, if you write FFh to CSNR, the actual number stored in CSNR is 3Fh.

Copyright © 2018, Texas Instruments Incorporated

Table 28-24. SPI Transmit Data Register 1 (SPIDAT1) Field Descriptions (continued)

Bit	Field	Value	Description
15-0	TXDATA	0-FFFFh	Transfer data. When written, these bits are copied to the shift register if it is empty. If the shift register is not empty, then they are held in TXBUF. SPIEN must be set to 1 before this register can be written to. Writing a 0 to SPIEN forces the lower 16 bits of SPIDAT1 to 0x0000. A write to this register (or to the TXDATA field only) drives the contents of the CSNR field on the $\overline{\text{SPICS}}$ pins, if the pins are configured as functional pins (automatic chip select, see Section 28.2.1). When this register is read, the contents of TXBUF, which holds the latest data written, will be returned. **Note: Regardless of the character length, the transmit data should be right-justified before writing to the SPIDAT1 register.**

23							16
LCSNR							
R-0							
15							0
RXDATA							
R-0							

LEGEND: R = Read only; -*n* = value after reset

Table 28-26. SPI Receive Buffer Register (SPIBUF) Field Descriptions

Bit	Field	Value	Description
31	RXEMPTY		Receive data buffer empty. When the host reads the RXDATA field or the entire SPIBUF register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into RXDATA and the RXEMPTY flag is cleared.
		0	New data has been received and copied into RXDATA.
		1	No data has been received since the last read of RXDATA.
			This flag gets set to 1 under the following conditions: • Reading the RXDATA field of the SPIBUF register. • Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG). Write-clearing the RXINTFLG bit before reading the SPIBUF indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA field of SPIBUF (or the entire register).
30	RXOVR		Receive data buffer overrun. When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to SPIBUF; the contents of SPIBUF are overwritten only after it is read by the Peripheral(VBUSP) master (CPU, DMA, or other host processor). If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVECTx shows the RXOVRN condition. Two read operations from the SPIBUF register are required to reach the overwritten buffer word (one to read SPIBUF, which then transfers RXDATA into SPIBUF for the second read). **Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.** **Note: A special condition under which RXOVR flag gets set. If both SPIBUF and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.**
		0	No receive data overrun condition occurred since last read of the data field.
		1	A receive data overrun condition occurred since last read of the data field.
29	TXFULL		Transmit data buffer full. This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag.
		0	The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.
		1	The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.

Copyright © 2018, Texas Instruments Incorporated

Table 28-26. SPI Receive Buffer Register (SPIBUF) Field Descriptions (continued)

Bit	Field	Value	Description
28	BITERR		Bit error. There was a mismatch of internal transmit data and transmitted data.
			Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		0	No bit error occurred.
		1	A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.
27	DESYNC		Desynchronization of slave device. This bit is valid in master mode only.
			The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus $t_{T2EDELAY}$. If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.
			Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always guaranteed to be for the current buffer.
			Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		0	No slave desynchronization is detected.
		1	A slave device is desynchronized.
26	PARITYERR		Parity error. The calculated parity differs from the received parity bit.
			If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set.
			Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		0	No parity error is detected.
		1	A parity error occurred.
25	TIMEOUT		Time-out because of non-activation of $\overline{\text{SPIENA}}$ pin.
			The SPI generates a time-out when the slave does not respond in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition, the TIMEOUT flag in the status field of the corresponding buffer and in the SPI Flag Register (SPIFLG) is set.
			This bit is valid only in master mode.
			Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		0	No $\overline{\text{SPIENA}}$ pin time-out occurred.
		1	An $\overline{\text{SPIENA}}$ signal time-out occurred.
24	DLENERR		Data length error flag.
			Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		0	No data-length error occurred.
		1	A data length error occurred.
23-16	LCSNR	0-FFh	Last chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It contains the chip select number that was activated during the last word transfer.
15-0	RXDATA	0-FFFFh	SPI receive data. This is the received word, transferred from the receive shift-register at the end of a transfer. Regardless of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.

Table 28-28. SPI Delay Register (SPIDELAY) Field Descriptions

Bit	Field	Value	Description
31-24	C2TDELAY	0-FFh	Chip-select-active to transmit-start delay. See Figure 28-51 for an example. C2TDELAY is used only in master mode. It defines a setup time (for the slave device) that delays the data transmission from the chip select active edge by a multiple of VCLK cycles. The setup time value is calculated as follows. $t_{C2TDELAY}$ = (C2TDELAY + 2) × VCLK Period Example: VCLK = 25 MHz -> VCLK Period = 40ns; C2TDELAY = 07h; > $t_{C2TDELAY}$ = 360 ns When the chip select signal becomes active, the slave has to prepare data transfer within 360 ns. **Note: If phase = 1, the delay between SPICS falling edge to the first edge of SPICLK will have an additional 0.5 SPICLK period delay. This delay is as per the SPI protocol.**

Copyright © 2018, Texas Instruments Incorporated

Table 28-28. SPI Delay Register (SPIDELAY) Field Descriptions (continued)

Bit	Field	Value	Description
23-16	T2CDELAY	0-FFh	Transmit-end-to-chip-select-inactive-delay. See Figure 28-52 for an example. T2CDELAY is used only in master mode. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of VCLK cycles after the last bit is transferred. The hold time value is calculated as follows: $t_{T2CDELAY}$ = (T2CDELAY +1) × VCLK Period Example: VCLK = 25 MHz -> VCLK Period = 40ns; T2CDELAY = 03h; > $t_{T2CDELAY}$ = 160 ns After the last data bit (or parity bit) is being transferred the chip select signal is held active for 160 ns. **Note: If phase = 0, then between the last edge of SPICLK and rise-edge of SPICS there will be an additional delay of 0.5 SPICLK period. This is as per the SPI protocol.** Both C2TDELAY and T2CDELAY counters do not have any dependency on the $\overline{\text{SPIENA}}$ pin value. Even if the $\overline{\text{SPIENA}}$ pin is asserted by the slave, the master will continue to delay the start of SPICLK until the C2TDELAY counter overflows. Similarly, even if the $\overline{\text{SPIENA}}$ pin is deasserted by the slave, the master will continue to hold the $\overline{\text{SPICS}}$ pins active until the T2CDELAY counter overflows. In this way, it is guaranteed that the setup and hold times of the $\overline{\text{SPICS}}$ pins are determined by the delay timers alone. To achieve better throughput, it should be ensured that these two timers are kept at the minimum possible values.
15-8	T2EDELAY	0-FFh	Transmit-data-finished to ENA-pin-inactive time-out. T2EDELAY is used in master mode only. It defines a time-out value as a multiple of SPI clock before $\overline{\text{SPIENA}}$ signal has to become inactive and after $\overline{\text{SPICS}}$ becomes inactive. SPICLK depends on which data format is selected. If the slave device is missing one or more clock edges, it becomes de-synchronized. In this case, although the master has finished the data transfer, the slave is still waiting for the missed clock pulses and the ENA signal is not disabled. The T2EDELAY defines a time-out value that triggers the DESYNC flag, if the $\overline{\text{SPIENA}}$ signal is not deactivated in time. The DESYNC flag is set to indicate that the slave device did not de-assert its $\overline{\text{SPIENA}}$ pin in time to acknowledge that it received all bits of the sent word. See Figure 28-53 for an example of this condition. **Note: DESYNC is also set if the SPI detects a de-assertion of $\overline{\text{SPIENA}}$ before the end of the transmission. The time-out value is calculated as follows:** $t_{T2EDELAY}$ = T2EDELAY/SPIclock Example: SPIclock = 8 Mbit/s; T2EDELAY = 10h; > $t_{T2EDELAY}$ = 2 µs The slave device has to disable the ENA signal within 2, otherwise DESYNC is set and an interrupt is asserted (if enabled).
7-0	C2EDELAY	0-FFh	Chip-select-active to ENA-signal-active time-out. C2EDELAY is used only in master mode and it applies only if the addressed slave generates an ENA signal as a hardware handshake response. C2EDELAY defines the maximum time between when the SPI activates the chip-select signal and the addressed slave has to respond by activating the ENA signal. C2EDELAY defines a time-out value as a multiple of SPI clocks. The SPI clock depends on whether data format 0 or data format 1 is selected. See Figure 28-54 for an example of this condition. **Note: If the slave device does not respond with the ENA signal before the time-out value is reached, the TIMEOUT flag in the SPIFLG register is set and a interrupt is asserted (if enabled).** If a time-out occurs, the SPI clears the transmit request of the timed-out buffer, sets the TIMEOUT flag for the current buffer, and continues with the transfer of the next buffer in the sequence that is enabled. The timeout value is calculated as follows: $t_{C2EDELAY}$ = C2EDELAY/SPIclock Example: SPIclock = 8 Mbit/s; C2EDELAY = 30 h; > $t_{C2EDELAY}$ = 6 ms The slave device has to activate the ENA signal within 6 ms after the SPI has activated the chip select signal ($\overline{\text{SPICS}}$), otherwise the TIMEOUT flag is set and an interrupt is asserted (if enabled).

PRESCALE						Reserved			CHARLEN						
R/WP-0						R-0			R/WP-0						

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; *-n* = value after reset

Table 28-30. SPI Data Format Registers (SPIFMTn) Field Descriptions

Bit	Field	Value	Description
31-24	WDELAY	0-FFh	Delay in between transmissions for data format x (x= 0,1,2,3).Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to: WDELAY × P_{VCLK} + 2 × P_{VCLK} P_{VCLK} -> Period of VCLK.
23	PARPOL		Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3).
		0	An even parity flag is added at the end of the transmit data stream.
		1	An odd parity flag is added at the end of the transmit data stream.
22	PARITYENA		Parity enable for data format x. No parity generation/ verification is performed for this data format.
		0	A parity bit is transmitted at the end of each transmitted word. At the end of a transfer the parity generator compares the received parity bit with the locally-calculated parity flag. If the parity bits do not match the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit.
		1	**Note: If an uncorrectable error flag is set in a slave-mode SPI, then the wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SOMI pins will be forced to transmit all 0s, and the parity bit will be transmitted as 1 if even parity is selected and as 0 if odd parity is selected (using the PARPOLx bit of this register). This behavior occurs regardless of an uncorrectable parity error on either TXRAM or RXRAM.**
21	WAITENA		The master waits for the ENA signal from slave for data format x. WAITENA is valid in master mode only. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines, for each transferred word, whether the addressed slave generates the ENA signal or not.
		0	The SPI does not wait for the ENA signal from the slave and directly starts the transfer.
		1	Before the SPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the master aborts the transfer and sets the TIMEOUT error flag.
20	SHIFTDIR		Shift direction for data format x. With bit SHIFTDIRx, the shift direction for data format x (x=0,1,2,3) can be selected.
		0	MSB is shifted out first.
		1	LSB is shifted out first.

Copyright © 2018, Texas Instruments Incorporated

Table 28-30. SPI Data Format Registers (SPIFMTn) Field Descriptions (continued)

Bit	Field	Value	Description
19	HDUPLEX_ENAx		Half Duplex transfer mode enable for Data Format x. This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin..
		0	Normal Full Duplex transfer.
		1	If MASTER = 1, SIMO pin will act as an RX pin (No TX possible) If MASTER = 0, SIMO pin will act as a TX pin (No RX possible). For all normal operations, HDUPLEX_ENAx bits should always remain 0. It is intended for the usage when the SIMO pin is used for both TX & RX operations at different times.
18	DIS_CS_TIMERS		Disable chip-select timers for this format. The C2TDELAY and T2CDELAY timers are by default enabled for all the data format registers. Using this bit, these timers can be disabled for a particular data format, if they are not required. When a master is handling multiple slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the chip-select delay timers for any slaves.
		0	Both C2TDELAY and T2CDELAY counts are inserted for the chip selects.
		1	No C2TDELAY or T2CDELAY is inserted in the chip select timings.
17	POLARITY		SPI data format x clock polarity. POLARITYx defines the clock polarity of data format x. The following restrictions apply when switching clock phase and/or polarity: • In 3-pin/4-pin with nENA pin configuration of a slave SPI, the clock phase and polarity cannot be changed on-the-fly between two transfers. The slave should be reset and reconfigured if clock phase/polarity needs to be switched. In summary, SPI format switching is not fully supported in slave mode. • Even while using chip select pins, the polarity of SPICLK can be switched only while the slave is not selected by a valid chip select. The master SPI should ensure that while switching SPICLK polarity, it has deselected all of its slaves. Otherwise, the switching of SPICLK polarity may be incorrectly treated as a clock edge by some slaves.
		0	If POLARITYx is cleared to 0, the SPI clock signal is low-inactive, that is, before and after data transfer the clock signal is low.
		1	If POLARITYx is set to 1, the SPI clock signal is high-inactive, that is, before and after data transfer the clock signal is high.
16	PHASE		SPI data format x clock delay. PHASEx defines the clock delay of data format x.
		0	If PHASEx is cleared to 0, the SPI clock signal is not delayed versus the transmit/receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge.
		1	If PHASEx is set to 1, the SPI clock signal is delayed by a half SPI clock cycle versus the transmit/receive data stream. The first transmit bit has to output prior to the first clock edge. The master and slave receive the first bit with the first edge.
15-8	PRESCALE		SPI data format x prescaler. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is use to derive SPICLK from VCLK. If the SPI is configured as slave, PRESCALEx **does not need** to be configured. The clock rate for data format x can be calculated as: $BR_{Formatx}$ = VCLK / (PRESCALEx + 1) **Note: When PRESCALEx is cleared to 0, the SPI clock rate defaults to VCLK/2.**
7-5	Reserved	0	Reads return 0. Writes have no effect.
4-0	CHARLEN	0-1Fh	SPI data format x data-word length. CHARLENx defines the word length of data format x. Legal values are 0x02 (data word length = 2 bit) to 10h (data word length = 16). Illegal values, such as 00 or 1Fh are not allowed; their effect is indeterminate.

28.3.22 Interrupt Vector 0 (INTVECT0)

NOTE: The TG interrupt is not available in MibSPI in compatibility mode. Therefore, there is no possibility to access this register in compatibility mode.

Figure 28-57. Interrupt Vector 0 (NTVECT0) [offset = 60h]

31	16
Reserved	
R-0	

15	6	5	1	0
Reserved		INTVECT0		SUSPEND0
R-0		R-0		R-0

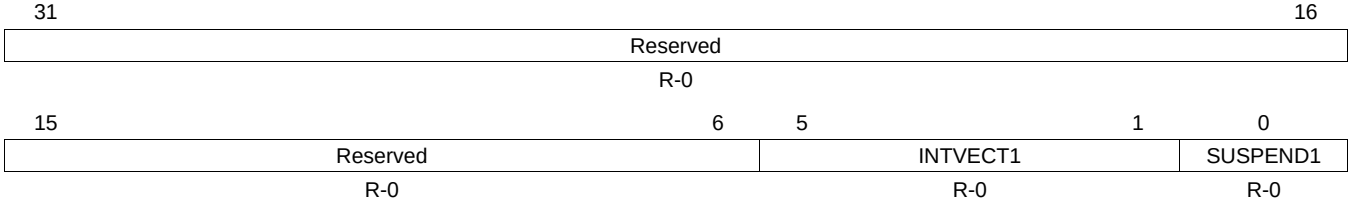
LEGEND: R = Read only; -*n* = value after reset

Table 28-31. Transfer Group Interrupt Vector 0 (INTVECT0)

Bit	Field	Value	Description
31-6	Reserved	0	Reads return 0. Writes have no effect.
5-1	INTVECT0		INTVECT0. Interrupt vector for interrupt line INT0.
			Returns the vector of the pending interrupt at interrupt line INT0. If more than one interrupt is pending, INTVECT0 always references the highest prior interrupt source first.
			Note: This field reflects the status of the SPIFLG register in vector format. Any updates to the SPIFLG register will automatically cause updates to this field.
		0	There is no pending interrupt.
		1h ÷ x	Transfer group x (x=0,..,15) has a pending interrupt. SUSPEND0 reflects the type of interrupt (*suspended* or *finished*).
		11h	Error Interrupt pending. The lower half of SPIFLG contains more details about the type of error.
		13h	The pending interrupt is a Receive Buffer Overrun interrupt.
		12h	**SPI mode:** The pending interrupt is a Receive Buffer Full interrupt. **Mib mode:** Reserved. This bit combination should not occur.
		14h	**SPI mode:** The pending interrupt is a Transmit Buffer Empty interrupt. **Mib mode:** Reserved. This bit combination should not occur.
		All Other Combinations	**SPI mode:** Reserved. These bit combinations should not occur.
0	SUSPEND0		Transfer suspended / Transfer finished interrupt flag.
			Every time INTVECT0 is read by the host, the corresponding interrupt flag of the referenced transfer group is cleared and INTVECT0 is updated with the vector coming next in the priority chain.
		0	The interrupt type is a transfer finished interrupt. In other words, the buffer array referenced by INTVECT0 has asserted an interrupt because all of data from the transfer group has been transferred.
		1	The interrupt type is a transfer suspended interrupt. In other words, the transfer group referenced by INTVECT0 has asserted an interrupt because the buffer to be transferred next is in suspend-to-wait mode.

NOTE: Reading from the INTVECT0 register when Transmit Empty is indicated does not clear the TXINTFLG flag in the SPI Flag Register (SPIFLG). Writing a new word to the SPIDATx register clears the Transmit Empty interrupt.

Copyright © 2018, Texas Instruments Incorporated



NOTE: In multi-buffer mode, INTVECT0 contains the interrupt for the highest priority transfer group. A read from INTVECT0 automatically causes the next-highest priority transfer group's interrupt status to get loaded into INTVECT0 and its corresponding SUSPEND flag to get loaded into SUSPEND0. The transfer group with the lowest number has the highest priority, and the transfer group with the highest number has the lowest priority.

Reading the INTVECT0 register when the RXOVRN interrupt is indicated in multi-buffer mode does not clear the RXOVRN flag and hence does not clear the vector. The RXOVRN interrupt vector may be cleared in multi-buffer mode either by write-clearing the RXOVRN flag in the SPI Flag Register (SPIFLG) or by reading the RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR).

28.3.23 Interrupt Vector 1 (INTVECT1)

NOTE: The TG interrupt is not available in SPI in compatibility mode compatibility mode. Therefore, there is no possibility to access this register in compatibility mode.

Figure 28-58. Interrupt Vector 1 (INTVECT1) [offset = 64h]

LEGEND: R = Read only; -*n* = value after reset

Table 28-32. Transfer Group Interrupt Vector 1 (INTVECT1)

Bit	Field	Value	Description
31-6	Reserved	0	Reads return 0. Writes have no effect.
5-1	INTVECT1		INTVECT1. Interrupt vector for interrupt line INT1. Returns the vector of the pending interrupt at interrupt line INT1. If more than one interrupt is pending, INTVECT1 always references the highest prior interrupt source first. **Note: This field reflects the status of the SPIFLG register in vector format. Any updates to the SPIFLG register will automatically cause updates to this field.**
		0	There is no pending interrupt. **SPI mode only.**
		11h	Error Interrupt pending. The lower half of SPIINT1 contains more details about the type of error. **SPI mode only.**
		13h	The pending interrupt is a Receive Buffer Overrun interrupt. **SPI mode only.**
		12h	The pending interrupt is a Receive Buffer Full interrupt. **SPI mode only.**
		14h	The pending interrupt is a Transmit Buffer Empty interrupt. **SPI mode only.**
		All Other Combinations	Reserved. These bit combinations should not occur. **SPI mode only.**
0	SUSPEND1		Transfer suspended / Transfer finished interrupt flag. Every time INTVECT1 is read by the host, the corresponding interrupt flag of the referenced transfer group is cleared and INTVECT1 is updated with the vector coming next in the priority chain.
		0	The interrupt type is a transfer finished interrupt. In other words, the buffer array referenced by INTVECT1 has asserted an interrupt because all of data from the transfer group has been transferred.
		1	The interrupt type is a transfer suspended interrupt. In other words, the transfer group referenced by INTVECT1 has asserted an interrupt because the buffer to be transferred next is in suspend-to-wait mode.

Copyright © 2018, Texas Instruments Incorporated

NOTE: Reading from the INTVECT1 register when Transmit Empty is indicated does not clear the TXINTFLG flag in the SPI Flag Register (SPIFLG). Writing a new word to the SPIDATx register clears the Transmit Empty interrupt.

NOTE: In multi-buffer mode, INTVECT1 contains the interrupt for the highest priority transfer group. A read from INTVECT1 automatically causes the next-highest priority transfer group's interrupt status to get loaded into INTVECT1 and its corresponding SUSPEND flag to get loaded into SUSPEND1. The transfer group with the lowest number has the highest priority, and the transfer group with the highest number has the lowest priority.

Reading the INTVECT1 register when the RXOVRN interrupt is indicated in multi-buffer mode does not clear the RXOVRN flag and hence does not clear the vector. The RXOVRN interrupt vector may be cleared in multi-buffer mode either by write-clearing the RXOVRN flag in the SPI Flag Register (SPIFLG) or by reading the RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR).

28.3.25 Parallel/Modulo Mode Control Register (SPIPMCTRL)

NOTE: Do not configure MODCLKPOLx and MMODEx bits since this device does not support modulo mode.

NOTE: The bits of this register are used in conjunction with the SPIFMTx registers. Each byte of this register corresponds to one of the SPIFMTx registers.

1. Byte0 (Bits 7:0) are used when SPIFMT0 register is selected by DFSEL[1:0] = 00 in the control field of a buffer.

2. Byte1 (Bits 15:8) are used when SPIFMT1 register is selected by DFSEL[1:0] = 01 in the control field of a buffer.

3. Byte2 (Bits 23:16) are used when SPIFMT2 register is selected by DFSEL[1:0] = 10 in the control field of a buffer.

4. Byte3 (Bits31:24) are used when SPIFMT3 register is selected by DFSEL[1:0] = 11 in the control field of a buffer.

Table 28-34. SPI Parallel/Modulo Mode Control Register (SPIPMCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
25-24	PMODE3		Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2, 4, or 8 data lines.
		0	Normal operation/1-data line (MMODE3 should be set to 000).
		1h	2-data line mode (MMODE3 should be set to 000).
		2h	4-data line mode (MMODE3 should be set to 000).
		3h	8-data line mode (MMODE3 should be set to 000).
23-22	Reserved	0	Reads return 0. Writes have no effect.
21	MODCLKPOL2		Modulo mode SPICLK polarity. This bit determines the polarity of the SPICLK in modulo mode only. If the MMODE2 bits are 000, this bit will be ignored.
		0	Normal SPICLK in all the modes.
		1	Polarity of the SPICLK will be inverted if Modulo mode is selected.
20-18	MMODE2		These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if modulo option is supported by the module).
		0	1-data line mode (default). (PMODE2 should be set to 00).
		1h	2-data line mode (PMODE2 should be set to 00).
		2h	3-data line mode (PMODE2 should be set to 00).
		3h	4-data line mode (PMODE2 should be set to 00).
		4h	5-data line mode (PMODE2 should be set to 00).
		5h	6-data line mode (PMODE2 should be set to 01).
		6h-7h	Reserved
17-16	PMODE2		Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2, 4, or 8 data lines.
		0	Normal operation/1-data line (MMODE2 should be set to 000).
		1h	2-data line mode (MMODE2 should be set to 000).
		2h	4-data line mode (MMODE2 should be set to 000).
		3h	8-data line mode (MMODE2 should be set to 000).
15-12	Reserved	0	Reads return 0. Writes have no effect.
13	MODCLKPOL1		Modulo mode SPICLK polarity. This bit determines the polarity of the SPICLK in modulo mode only. If the MMODE1 bits are 000, this bit will be ignored.
		0	Normal SPICLK in all the modes.
		1	Polarity of the SPICLK will be inverted if Modulo mode is selected.
12-10	MMODE1		These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if modulo option is supported by the module).
		0	1-data line mode (default). (PMODE1 should be set to 00).
		1h	2-data line mode (PMODE1 should be set to 00).
		2h	3-data line mode (PMODE1 should be set to 00).
		3h	4-data line mode (PMODE1 should be set to 00).
		4h	5-data line mode (PMODE1 should be set to 00).
		5h	6-data line mode (PMODE1 should be set to 01).
		6h-7h	Reserved
9-8	PMODE1		Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2, 4, or 8 data lines.
		0	Normal operation/1-data line (MMODE1 should be set to 000).
		1h	2-data line mode (MMODE1 should be set to 000).
		2h	4-data line mode (MMODE1 should be set to 000).
		3h	8-data line mode (MMODE1 should be set to 000).
7-6	Reserved	0	Reads return 0. Writes have no effect.
5	MODCLKPOL0		Modulo mode SPICLK polarity. This bit determines the polarity of the SPICLK in modulo mode only. If the MMODE0 bits are 000, this bit will be ignored.
		0	Normal SPICLK in all the modes.
		1	Polarity of the SPICLK will be inverted if Modulo mode is selected.

NOTE: Accessibility of Registers

Registers from this offset address onwards are not accessible in SPI compatibility mode. They are accessible only in the multi-buffer mode.

28.3.26 Multi-buffer Mode Enable Register (MIBSPIE)

NOTE: Accessibility of Multi-Buffer RAM

The multi-buffer RAM is not accessible unless the MSPIENA bit is set to 1. The only exception to this is in test mode, where, by setting RXRAMACCESS to 1, the multi-buffer RAM can be fully accessed for both read and write.

Figure 28-61. Multi-buffer Mode Enable Register (MIBSPIE) [offset = 70h]

31	17	16
Reserved		RXRAM_ACCESS
R-0		R/WP-0

15	12	11	10	9	8	7	1	0
Reserved		EXTENDED_BUF_ENA				Reserved		MSPIENA
R-0		R/WP-5h						R/WP-0

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 28-35. Multi-buffer Mode Enable Register (MIBSPIE) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reads return 0. Writes have no effect.
16	RXRAM_ACCESS		Receive-RAM access control. During normal operating mode of SPI, the receive data/status portion of multi-buffer RAM is read-only. To enable testing of receive RAM, direct read/write access is enabled by setting this bit.
		0	The RX portion of multi-buffer RAM is not writable by the CPU.
		1	The whole of multi-buffer RAM is fully accessible for read/write by the CPU.
			Note: The RX RAM ACCESS bit remains 0 after reset and it should remain set to 0 at all times, except when testing the RAM. SPI should be given a local reset by using the nRESET (SPIGCR0[0]) bit after RAM testing is performed so that the multi-buffer RAM gets re-initialized.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	EXTENDED_BUF_ENA		Enables the support for 256 buffers. By default MibSPI supports up to 128 buffers for both TX and RX. Refer to the device specific datasheet if 256 buffer extension is implemented for the specific MibSPI instance in the device.
		5h	Write: Disables the Extended Buffer mode - MibSPI supports only 128 buffers (default).
		Ah	Write: Enables the Extended Buffer mode - up to 256 buffers can be used.
		all others	All other values - writes are ignored and the values are not updated into this field. The state of the feature remains unchanged.
			Read: Returns the current value of this field.
7-1	Reserved	0	Reads return 0. Writes have no effect.
0	MSPIENA		Multi-buffer mode enable. After power-up or reset, MSPIENA remains cleared, which means that the SPI runs in compatibility mode by default. If multi-buffer mode is desired, this register should be configured first after configuring the SPIGCR0 register. If MSPIENA is not set to 1, the multi-buffer mode registers are not writable.
		0	The SPI runs in compatibility mode, that is, in this mode the MibSPI is fully code-compliant to the standard device SPI. No multi-buffered-mode features are supported.
		1	The SPI is configured to run in multi-buffer mode.

28.3.27 TG Interrupt Enable Set Register (TGITENST)

The register TGITENST contains the TG interrupt enable flags for transfer-finished and for transfer-suspended events. Each of the enable bits in the higher half-word and the lower half-word of TGITENST belongs to one TG.

The register map shown in Figure 28-62 and Table 28-36 represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

Figure 28-62. TG Interrupt Enable Set Register (TGITENST) [offset = 74h]

Table 28-36. TG Interrupt Enable Set Register (TGITENST) Field Descriptions

Bit	Field	Value	Description
31-16	SETINTENRDY[*n*]		TG interrupt set (enable) when transfer finished. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on.
		0	Read: The TGx-completed interrupt is disabled. This interrupt does not get generated when TGx completes. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is enabled. The interrupt gets generated when TGx completes. Write: Enable the TGx-completed interrupt. The interrupt gets generated when TGx completes.
15-0	SETINTENSUS[*n*]		TG interrupt set (enabled) when transfer suspended. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on.
		0	Read: The TGx-completed interrupt is disabled. This interrupt does not get generated when TGx is suspended. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is enabled. The interrupt gets generated when TGx is suspended. Write: Enable the TGx-completed interrupt. The interrupt gets generated when TGx is suspended.

Copyright © 2018, Texas Instruments Incorporated

28.3.28 TG Interrupt Enable Clear Register (TGITENCR)

The register TGITENCR is used to clear the interrupt enables for the TG-completed interrupt and the TG-suspended interrupts.

The register map shown in Figure 28-63 and Table 28-37 represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

28.3.29 Transfer Group Interrupt Level Set Register (TGITLVST)

The register TGITLVST sets the level of interrupts for transfer completed interrupt and for transfer suspended interrupt to level 1.

The register map shown in Figure 28-64 andTable 28-38 represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

28.3.31 Transfer Group Interrupt Flag Register (TGINTFLAG)

The TGINTFLAG register comprises the transfer group interrupt flags for transfer-completed interrupts (INTFLGRDYx) and for transfer-suspended interrupts (INTFLGSUSx). Each of the interrupt flags in the higher half-word and the lower half-word of TGINTFLAG belongs to one TG.

The register map shown in Figure 28-66 and Table 28-40 represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

Figure 28-66. Transfer Group Interrupt Flag Register (TGINTFLAG) [offset = 84h]

INTFLGSUS[15:0]	
R/W1C-0	

LEGEND: R/W = Read/Write; W1C = Write 1 to clear; -*n* = value after reset

Table 28-40. Transfer Group Interrupt Level Clear Register (TGITLVCR) Field Descriptions

Bit	Field	Value	Description
31-16	INTFLGRDY[*n*]		Transfer-group interrupt flag for a transfer-completed interrupt. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on. **Note: Read Clear Behavior. Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGRDYx referenced by the vector number given by INTVECT0/INTVECT1 bits, if the SUSPEND[0:1] bit in the vector registers is 0.**
		0	Read: No transfer-completed interrupt occurred since last clearing of the INTFLGRDYx flag. Write: A write of 0 to this bit has no effect.
		1	Read: A transfer finished interrupt from transfer group x occurred. No matter whether the interrupt is enabled or disabled (INTENRDYx = don't care) or whether the interrupt is mapped to INT0 or INT1, INTFLGRDYx is set right after the transfer from TGx is finished. Write: The corresponding bit flag is cleared.
15-0	INTFLGSUS[*n*]		Transfer-group interrupt flag for a transfer-suspend interrupt. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on. **Note: Read Clear Behavior. Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGSUSx referenced by the vector number given by INTVECT0/INTVECT1 bits, if the SUSPEND[0:1] bit in the corresponding vector registers is 1.**
		0	Read: No transfer-suspended interrupt occurred since the last clearing of the INTFLGSUSx flag. Write: A write of 0 to this bit has no effect.
		1	Read: A transfer-suspended interrupt from TGx occurred. No matter whether the interrupt is enabled or disabled (INTENSUSx = don't care) or whether the interrupt is mapped to INT0 or INT1, INTFLGSUSx is set right after the transfer from transfer group x is suspended. Write: The corresponding bit flag is cleared.

28.3.32 Tick Count Register (TICKCNT)

One of the trigger sources for TGs is an internal periodic time trigger. This time trigger is called a tick counter and is basically a down-counter with a preload/reload value. Every time the tick counter detects an underflow it reloads the initial value and toggles the trigger signal provided to the TGs.

The trigger signal, shown in Figure 28-67 as a square wave, illustrates the different trigger event types for the TGs (for example, rising edge, falling edge, and both edges).

Figure 28-67. Tick Counter Operation

This register is shown in Figure 28-68 and described in Table 28-41.

Figure 28-68. Tick Count Register (TICKCNT) [offset = 90h]

31	30	29 28	27 16
TICKENA	RELOAD	CLKCTRL	Reserved
R/W-0	R/S-0	R/W-0	R-0

15 0
TICKVALUE
R/W-0

LEGEND: R = Read only; R/W = Read/Write; S = Set; -*n* = value after reset

Table 28-41. Tick Count Register (TICKCNT) Field Descriptions

Bit	Field	Value	Description
31	TICKENA		Tick counter enable.
		0	The internal tick counter is disabled. The counter value remains unchanged.
			Note: When the tick counter is disabled, the trigger signal is forced low.
		1	The internal tick counter is enabled and is clocked by the clock source selected by CLKCTRL. When TICKENA goes from 0 to 1, the tick counter is automatically loaded with the contents of TICKVALUE.
30	RELOAD		Pre-load the tick counter. RELOAD is a set-only bit; writing a 1 reloads the tick counter with the value stored in TICKVALUE. Reading RELOAD always returns a 0.
			Note: When the tick counter is reloaded by the RELOAD bit, the trigger signal is not toggled.
29-28	CLKCTRL		Tick counter clock source control. CLKCTRL defines the clock source that is used to clock the internal tick counter.
		0	SPICLK of data word format 0 is selected as the clock source of the tick counter.
		1h	SPICLK of data word format 1 is selected as the clock source of the tick counter.
		2h	SPICLK of data word format 2 is selected as the clock source of the tick counter.
		3h	SPICLK of data word format 3 is selected as the clock source of the tick counter.
27-16	Reserved	0	Reads return 0. Writes have no effect.
15-0	TICKVALUE	0-FFFFh	Initial value for the tick counter. TICKVALUE stores the initial value for the tick counter. The tick counter is loaded with the contents of TICKVALUE every time an underflow condition occurs and every time the RELOAD flag is set by the host.

28.3.33 Last TG End Pointer (LTGPEND)

Figure 28-69. Last TG End Pointer (LTGPEND) [offset = 94h]

31 29	28 24	23 16
Reserved	TG IN SERVICE	Reserved
R-0	R-0	R-0

15 8	7 0
LPEND	Reserved
R/W-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 28-42. Last TG End Pointer (LTGPEND) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reads return 0. Writes have no effect.
28-24	TG IN SERVICE		The TG number currently being serviced by the sequencer. These bits indicate the current TG that is being serviced. This field can generally be used for code debugging.
		0	No TG is being serviced by the sequencer.
		1h	TG0 is being serviced by the sequencer.
		:	:
		10h	TG15 is being serviced by the sequencer.
			Note: The number of transfer groups varies by device.
		11h-1Fh	Invalid values.
23-16	Reserved	0	Reads return 0. Writes have no effect.
15-8	LPEND	0-FFh	Last TG end pointer. Usually the TG end address (PEND) is inherently defined by the start value of the starting pointer of the subsequent TG (PSTART). The TG ends one word before the next TG starts (PEND[x] = PSTART[x+1] - 1). For a full configuration of MibSPI, the last TG has no subsequent TG, that is, no end address is defined. Therefore, LPEND has to be programmed to specify explicitly the end address of the last TG.
			Note: For MibSPI1 that supports 256 buffers (values from 0-FFh), bit 15 is used. For MibSPI2-5 that support 128 buffers (values from 0-7Fh), bit 15 is reserved.
			Note: When using all 8 transfer groups, program the LPEND bits to define the end of the last transfer group. When using less than 8 transfer groups, leave the LPEND bits programmed to point to the end of the buffer and create a dummy transfer group that defines the end of your last intentional transfer group and occupies all the remaining buffer space.
7-0	Reserved	0	Reads return 0. Writes have no effect.

Copyright © 2018, Texas Instruments Incorporated

28.3.34 TGx Control Registers (TGxCTRL)

Each TG can be configured via one dedicated control register. The register description shows one control register (x) that is identical for all TGs. For example, the control register for TG2 is named TG2CTRL and is located at *base address + 98h + 4 × 2*. The actual number of available control registers varies by device.

Figure 28-70. MibSPI TG Control Registers (TGxCTRL) [offsets = 98h-D4h]

31	30	29	28	27 24	23 20	19 16
TGENA	ONESHOT	PRST	TGTD	Reserved	TRIGEVT	TRIGSRC
R/W-0	R/W-0	R/W-0	R-0	R-0	R/W-0	R/W-0

15 8	7 0
PSTART	PCURRENT
R/W-0	R-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 28-43. TG Control Registers (TGxCTRL) Field Descriptions

Bit	Field	Value	Description
31	TGENA		TGx enable. If the correct event (TRIGEVTx) occurs at the selected source (TRIGSRCx) a group transfer is initiated if no higher priority TG is in active transfer mode or if one or more higher-priority TGs are in transfer-suspend mode. Disabling a TG while a transfer is ongoing will finish the ongoing word transfer but not the whole group transfer.
		0	TGx is disabled.
		1	TGx is enabled.
30	ONESHOTx		Single transfer for TGx.
		0	TGx initiates a transfer every time a trigger event occurs and TGENA is set.
		1	A transfer from TGx will be performed only once (one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENAx control bit will be cleared and therefore no additional transfer can be triggered before the host enables the TG again. This one shot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data.
29	PRSTx		TGx pointer reset mode. Configures the way to resolve trigger events during an ongoing transfer. This bit is meaningful only for level-triggered TGs. Edge-triggered TGs cannot be restarted before their completion by another edge. The PRST bit will have no effect on this behavior. **Note: When the PRST bit is set, if the buffer being transferred at the time of a new trigger event is a LOCK, CSHOLD or NOBRK buffer, then only after finishing those transfers, the TG will be restarted. This means that even if the TG is retriggered, the TG will only be restarted after finishing the transfer of the first non-LOCK or non-CSHOLD buffer. In the case of the NOBRK buffer, after completing the ICOUNT number of transfers, the TG will be restarted from its PSTART.** This means that TX control fields such as LOCK and CSHOLD, and DMA control fields such as NOBRK have higher priority over anything else. They have the capability to delay the restart of the TG even if it is retriggered when PRST is 1.
		0	If a trigger event occurs during a transfer from TGx, the event is ignored and is not stored internally. The TGx transfer has priority over additional trigger events.
		1	The TGx pointer (PCURRENTx) will be reset to the start address (PSTARTx) when a valid trigger event occurs at the selected trigger source while a transfer from the same TG is ongoing. Every trigger event resets PCURRENTx no matter whether the concerned TG is in transfer mode or not. The trigger events have priority over the ongoing transfer.
28	TGTDx		TG triggered.
		0	TGx has not been triggered or is no longer waiting for service.
		1	TGx has been triggered and is either currently being serviced or waiting for servicing.
27-24	Reserved	0	Reads return 0. Writes have no effect.

Copyright © 2018, Texas Instruments Incorporated

Table 28-43. TG Control Registers (TGxCTRL) Field Descriptions (continued)

Bit	Field	Value		Description
23-20	TRIGEVTx			Type of trigger event. A level-triggered TG can be stopped by de-activating the level trigger. However, the following restrictions apply. • Deactivating the level trigger for a TG during a NOBRK transfer does not stop the transfers until all of the ICOUNT number of buffers are transferred for the NOBRK buffer. Once a NOBRK buffer is prefetched, the trigger event loses control over the TG until the NOBRK buffer transfer is completed. • Once the transfer of a buffer with CSHOLD or LOCK bit set starts, deactivating the trigger level does not stop the transfer until the sequencer completes the transfer of the next non-CSHOLD or non-LOCK buffer in the same TG. • Once the last buffer in a TG is pre-fetched, de-activating the trigger level does not stop the transfer group until the last buffer transfer is completed. This means even if the trigger level is deactivated at the beginning of the penultimate (one-before-last) buffer transfer, the sequencer continues with the same TG until it is completed.
		0	never	Never trigger TGx. This is the default value after reset.
		1h	rising edge	A rising edge (0 to 1) at the selected trigger source (TRIGSRCx) initiates a transfer for TGx.
		2h	falling edge	A falling edge (1 to 0) at the selected trigger source (TRIGSRCx) initiates a transfer for TGx.
		3h	both edges	Rising and falling edges at the selected trigger source (TRIGSRCx) initiates a transfer for TGx.
		4h	Rsvd	Reserved
		5h	high-active	While the selected trigger source (TRIGSRCx) is at a logic high level (1) the group transfer is continued and at the end of one group transfer restarted at the beginning. If the logic level changes to low (0) during an ongoing group transfer, the whole group transfer will be stopped. **Note: If ONESHOTx is set the transfer is performed only once.**
		6h	low-active	While the selected trigger source (TRIGSRCx) is at a logic low level (0) the group transfer is continued and at the end of one restarted at the beginning. If the logic level changes to high (1) during an ongoing group transfer, the whole group transfer will be stopped. **Note: If ONESHOTx is set the transfer is performed only once.**
		7h	always	A repetitive group transfer will be performed. **Note: By setting the TRIGSRC to 0, the TRIGEVT to 7h (ALWAYS), and the ONESHOTx bit to 1, software can trigger this TG. Upon setting the TGENA bit, the TG is immediately triggered.** **Note: If ONESHOTx is set the transfer is performed only once.**
		1xxx	Rsvd	Reserved

Table 28-43. TG Control Registers (TGxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description	
19-16	TRIGSRCx		Trigger source. After reset, the trigger sources of all TGs are disabled.	
		0	Disabled	
		1h	EXT0	External trigger source 0. The actual source varies per device (for example, HET I/O channel, event pin).
		2h	EXT1	External trigger source 1. The actual source varies per device (for example, HET I/O channel, event pin).
		3h	EXT2	External trigger source 2. The actual source varies per device (for example, HET I/O channel, event pin).
		4h	EXT3	External trigger source 3. The actual source varies per device (for example, HET I/O channel, event pin).
		5h	EXT4	External trigger source 4. The actual source varies per device (for example, HET I/O channel, event pin).
		6h	EXT5	External trigger source 5. The actual source varies per device (for example, HET I/O channel, event pin).
		7h	EXT6	External trigger source 6. The actual source varies per device (for example, HET I/O channel, event pin).
		8h	EXT7	External trigger source 7. The actual source varies per device (for example, HET I/O channel, event pin).
		9h	EXT8	External trigger source 8. The actual source varies per device (for example, HET I/O channel, event pin).
		Ah	EXT9	External trigger source 9. The actual source varies per device (for example, HET I/O channel, event pin).
		Bh	EXT10	External trigger source 10. The actual source varies per device (for example, HET I/O channel, event pin).
		Ch	EXT11	External trigger source 11. The actual source varies per device (for example, HET I/O channel, event pin).
		Dh	EXT12	External trigger source 12. The actual source varies per device (for example, HET I/O channel, event pin).
		Eh	EXT13	External trigger source 13. The actual source varies per device (for example, HET I/O channel, event pin).
		Fh	TICK	Internal periodic event trigger. The tick counter can initiate periodic group transfers.
15-8	PSTARTx	0-FFh	TG start address. PSTARTx stores the start address of the corresponding TG. The corresponding end address is inherently defined by the subsequent TG start address minus 1 (PENDx[TGx] = PSTARTx[TGx+1]-1). PSTARTx is copied into PCURRENTx when: • The TG is enabled. • The end of the TG is reached during a transfer. • A trigger event occurs while PRST is set to 1. **Note: For MibSPI1 that supports 256 buffers (values from 0-FFh), bit 15 is used. For MibSPI2-5 that support 128 buffers (values from 0-7Fh), bit 15 is reserved.**	
7-0	PCURRENTx	0-FFh	Pointer to current buffer. PCURRENT is read-only. PCURRENTx stores the address of the buffer that corresponds to this TG. If the TG switches from active transfer mode to suspend to wait, PCURRENTx contains the address of the currently suspended word. After the TG resumes from suspend to wait mode, the next buffer will be transferred; that is, no buffer data is transferred because of suspend to wait mode. **Note: For MibSPI1 that supports 256 buffers (values from 0-FFh), bit 7 is used. For MibSPI2-5 that support 128 buffers (values from 0-7Fh), bit 7 is reserved.**	

NOTE: Register bits vary by device

TG0 has the highest priority and TG15 has the lowest priority. Under the following conditions a lower priority TG cannot be interrupted by a higher priority TG.

1. When there is a CSHOLD or LOCK buffer, until the completion of the next buffer transfer which is a non-CSHOLD or non-LOCK buffer.
2. An entire sequence of words transferred for a NOBRK DMA buffer.
3. Once the last word in a TG is pre-fetched.

28.3.35 DMA Channel Control Register (DMAxCTRL)

Each DMA channel can be configured via one dedicated control register. The register description below shows one exemplary control register that is identical for all DMA channels; for example, the control register for DMA channel 0 is named DMA0CTRL. The MibSPI supports up to 8 bidirectional DMA channels.

The number of bidirectional DMA channels varies by device. The number of DMA channels and hence the number of DMA channel control registers may vary.

Figure 28-71. DMA Channel Control Register (DMAxCTRL) [offset = D8h-F4h]

R-0	R-0	R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

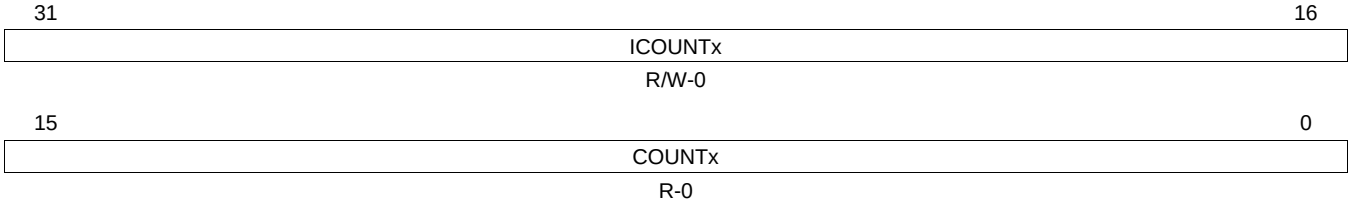
Table 28-44. DMA Channel Control Register (DMAxCTRL) Field Descriptions

Bit	Field	Value	Description
31	ONESHOT		Auto-disable of DMA channel after ICOUNT+1 transfers. **Note: This ONESHOT applies to the DMA channel identified by x and will autodisable based on ICOUNTx.**
		0	The length of the block transfer is fully controlled by the DMA controller. The enable bits RXDMAENAx and TXDMAENAx are not modified by the MibSPI.
		1	ONESHOT allows a block transfer of defined length (ICOUNTx+1), mainly controlled by the MibSPI and not by the DMA controller. After ICOUNTx +1 transfers, the enable bits RXDMAENAx and TXDMAENAx are automatically cleared by the MibSPI, hence no more DMA requests are generated. In conjunction with NOBRKx, a burst transfer can be initiated without any other transfer through another buffer.
30-24	BUFIDx	0-7Fh	Buffer utilized for DMA transfer. BUFIDx defines the buffer that is utilized for the DMA transfer. In order to synchronize the transfer with the DMA controller with the NOBRK condition the "suspend to wait until..." modes must be used.
23-20	RXDMA_MAPx	0-Fh	Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. RXDMA_MAPx defines the number of the physical DMA Request line that is connected to the receive path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set to 1, then RXDMA_MAPx shall differ from TXDMA_MAPx and shall differ from any other used physical DMA Request line. Otherwise unexpected interference may occur.
19-16	TXDMA_MAPx	0-Fh	Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. TXDMA_MAPx defines the number of the physical DMA Request line that is connected to the transmit path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set then TXDMA_MAPx shall differ from RXDMA_MAPx and shall differ from any other used physical DMA Request line. Otherwise unexpected interference may occur.
15	RXDMAENAx		Receive data DMA channel enable.
		0	No DMA request upon new receive data.
		1	The physical DMA channel for the receive path is enabled. The first DMA request pulse is generated after the first transfer from the referenced buffer (BUFIDx) is finished. The buffer should be configured in as "skip until RXEMPTY is set" or "suspend to wait until RXEMPTY is set" in order to ensure synchronization between the DMA controller and the MibSPI sequencer.

Copyright © 2018, Texas Instruments Incorporated

Table 28-44. DMA Channel Control Register (DMAxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
14	TXDMAENAx		Transmit data DMA channel enable.
		0	No DMA request upon new transmit data.
		1	The physical DMA channel for the transmit path is enabled. The first DMA request pulse is generated right after setting TXDMAENAx to load the first transmit data. The buffer should be configured in the as "skip until TXFULL is set" or "suspend to wait until TXFULL is set" in order to ensure synchronization between the DMA controller and the MibSPI sequencer.
13	NOBRKx		Non-interleaved DMA block transfer. This bit is available in master mode only. **Note: Special Conditions during a NOBRK Buffer Transfer. If a NOBRK DMA buffer is currently being serviced by the sequencer, then it is not allowed to be disabled prematurely.** During a NOBRK transfer, the following operations are not allowed: • Clearing the NOBRKx bit to 0 • Clearing the RXDMAENAx to 0 (if it is already 1) • Clearing the TXDMAENAx to 0 (if it is already 1) • Clearing the BUFMODE[2:0] bits to 000 **Note: Any attempts to perform these actions during a NOBRK transfer will produce unpredictable results.**
		0	DMA transfers through the buffer referenced by BUFIDx are interleaved by data transfers from other active buffers or TGs. Every time the sequencer checks the DMA buffer, it performs one transfer and then steps to the next buffer.
		1	NOBRKx ensures that ICOUNTx + 1 data transfers are performed from the buffer referenced by BUFIDx without a data transfer from any other buffer. The sequencer remains at the DMA buffer until ICOUNTx + 1 transfers have been processed.For example, this can be used to generate a burst transfer to one device without disabling the chip select signal in-between (the concerned buffer has to be configured with CSHOLD = 1). Another example would be to have a defined block data transfer in slave mode, synchronous to the master SPI. **Note: Triggering of higher priority TGs or enabling of higher priority DMA channels will not interrupt a NOBRK block transfer.**
12-8	ICOUNTx	0-1Fh	Initial count of DMA transfers. ICOUNTx is used to preset the transfer counter COUNTx. Every time COUNTx hits 0, it is reloaded with ICOUNTx. The real number of transfers equals ICOUNTx plus 1. If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the DMA channels. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer. If ONESHOTx and NOBRKx are not set, ICOUNTx should be 0. **Note: See Section 28.3.36 (ICOUNT) and Section 28.3.37 (DMACNTLEN) about how to increase the ICOUNT to a 16-bit value. With this extended capability, MibSPI can transfer a block of up to 65535 (65K) words without interleaving (if NOBRK is used) or without deasserting the chip select between the buffers (if CSHOLD is used).**
7	Reserved	0	Reads return 0. Writes have no effect.
6	COUNT BIT17x		The 17th bit of the COUNT field of DMAxCOUNT register.
5-0	COUNTx	0-3Fh	Actual number of remaining DMA transfers. This field contains the actual number of DMA transfers that remain, until the DMA channel is disabled, if ONESHOTx is set. **Note: If the TX and RX DMA requests are enabled, the COUNT register will be decremented when the RX has been serviced.**



Copyright © 2018, Texas Instruments Incorporated

28.3.36 DMAxCOUNT Register (ICOUNT)

NOTE: These registers are used only if the LARGE COUNT bit in the DMACNTLEN register is set.

The number of bidirectional DMA channels varies by device. The number of DMA channels and hence the number of DMA registers varies by device.

Figure 28-72. DMAxCOUNT Register (ICOUNT) [offset = F8h-114h]

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 28-45. MibSPI DMAxCOUNT Register (ICOUNT) Field Descriptions

Bit	Field	Value	Description
31-16	ICOUNTx	0-FFFFh	Initial number of DMA transfers. ICOUNTx is used to preset the transfer counter COUNTx. Every time COUNTx hits 0, it is reloaded with ICOUNTx. The real number of transfer equals ICOUNTx plus 1. If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the corresponding DMA channel. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer
15-0	COUNTx	0-FFFFh	Actual number of remaining DMA transfers. COUNTx Contains the actual number of DMA transfers that remain, until the DMA channel is disabled, if ONESHOTx is set. Since the real counter value is always ICOUNTx + 1, the 17th bit of COUNTx is available on DMACTRLx[6] bit. **Note: Usage Tip for Block Transfer Using a Single DMA Request. It is possible to use the multi-buffer RAM to transfer chunks of data to/from an external SPI. A DMA Controller can be used to handle the data in bursts. Suppose a chunk of 64 bytes of data needs to be transferred and a single DMA request needs to be generated at the end of transferring the 64 bytes. This can be easily achieved by configuring a TG register for the 64 buffer locations and using the DMAxCTRL/DMAxCOUNT registers to configure the last buffer (64th) of the TG as the BUFID and enable RXDMA (NOBRK = 0). At the end of the transfer of the 64th buffer, a DMA request will be generated on the selected DMA request channel. The DMA controller can do a burst read of all 64 bytes from RXRAM and/or then do a burst write to all 64 bytes to the TXRAM for the next chunk.**

Table 28-46. MibSPI DMA Large Count Register (DMACNTLEN) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reads return 0. Writes have no effect.
0	LARGE COUNT		Select either the 16-bit DMAxCOUNT counters or the smaller counters in DMAxCTRL.
		0	Select the DMAxCTRL counters. Writes to the DMAxCTRL register will modify the ICOUNT value. Reading ICOUNT and COUNT can be done from the DMAxCTRL register. The DMAxCOUNT register should not be used since any write to this register will be overwritten by a subsequent write to the DMAxCTRL register to set the TXDMAENA or RXDMAENA bits.
		1	Select the DMAxCOUNT counters. Writes to the DMAxCTRL register will not modify the ICOUNT value. The ICOUNT value must be written to in the DMAxCOUNT register before the RXDMAENA or TXDMAENA bits are set in the DMAxCTRL register. The DMAxCOUNT register should be used for reading COUNT or ICOUNT.

R-0		RC-x	

LEGEND: R/W = Read/Write; R = Read only; RC = Read to clear; -*n* = value after reset

Table 28-49. Uncorrectable Parity or Double-Bit ECC Error Address Register - RXRAM (UERRADDR1) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	Reads return 0. Writes have no effect.
10-0	UERRADDR1		Uncorrectable Parity or double-bit ECC error address This register holds the address of the RAM location, if a parity or double-bit ECC error is detected when reading the MibSPI (Receive) RXRAM. The address captured is byte aligned when RAM Parity Check is supported. This error address is frozen from being updated until it is read by the VBUS host. Reading this register clears its contents to the default value. The default value is 400h if Extended Buffer feature is enabled; else, it is 200h. Writes to this register are ignored.

NOTE: UERRADDR1 values

The offset address of RXRAM can vary from 000h-1FFh, if EXTENDED_BUF mode is disabled. If the EXTENDED_BUF mode is enabled, the offset address can vary from 000h-3FFh.

The register does not clear its contents during and after any of the module-level resets, System-level resets, or even Power-on Reset.

NOTE: A read to UERRADDR1 register will clear the UERR_FLG1 in PAR_ECC_STAT register. However, in emulation mode (VBUSP_EMUDBG = 1), the read to UERRADDR1 register does not clear the corresponding UERR_FLG1.

After a power-on reset the contents of this register will be unpredictable. So, a read operation can be performed after power-up to clear its contents if required. Contents of this register are meaningful only when UERR_FLG1 is set to 1.

If ECC feature is implemented, the Sequencer FSM clearing the TXFULL flag (after a TXRAM location read out and written to the shift register for transfer) will trigger read-modify-write operation to the RXRAM. Similarly, each time FSM reads a TXRAM to transfer it out, the corresponding RXRAM location is also automatically read to determine the status of the buffer. A double-bit error could be detected during these FSM read operations and result in error address and flags getting captured.

NOTE: Clearing of UERR status and address registers

After completing a memory test sequence, specifically where parity or ECC features are tested, user must read back the status flags in PAR_ECC_STAT and UERRADDRx registers and ensure that they are in normal clear state by reading/writing appropriately. This can be performed before the start of a normal multi-buffer mode transactions as well.

If RAM Parity Check is supported, UERRADDR1[1:0] values will reflect the byte positions of failed byte based on the following scheme to take care of Endianness of memory organization.

Copyright © 2018, Texas Instruments Incorporated

Table 28-50. Effect of BIG_ENDIAN Port on UERRADDR1[1:0] Bits

	Endianness		Fault Location is Among the RAM Bits
	1 (Big Endian)	0 (Little Endian)	
UERRADDR1[1:0]	00	11	7:0
	01	10	15:8
	10	01	23:16
	11	00	31:24

NOTE: When ECC is supported, UERRADDR0 will indicate only word address. UERRADDR0[1:0] will always be 00.

LEGEND: R/W = Read/Write; R = Read only; RC = Read to clear; -*n* = value after reset

Table 28-51. Uncorrectable Parity or Double-Bit ECC Error Address Register - TXRAM (UERRADDR0) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	Reads return 0. Writes have no effect.
10-0	UERRADDR0		Uncorrectable Parity or double-bit ECC error address. This register holds the address when a parity error is generated while reading the MibSPI (Transmit) TXRAM. The TXRAM can be read either by CPU or by the MibSPI Sequencer FSM logic for transmission. The address captured is byte aligned. This error address is frozen from being updated until it is read by the VBUSP host. Reading this register clears its contents to the default value of 000. Writes to this register are ignored.

NOTE: UERRADDR0 values

The offset address of TXRAM can vary from 200h-3FFh, if EXTENDED_BUF mode is disabled. If the EXTENDED_BUF mode is enabled, the offset address can vary from 400h-7FFh.

The register does not clear its contents during and after any of the module-level resets, System-level resets, or even Power-on Reset.

NOTE: A Read to UERRADDR0 register will clear the UERR_FLG0 in PAR_ECC_STAT register. However, in emulation mode (VBUSP_EMUDBG = 1), the read to UERRADDR0 register does not clear the corresponding UERR_FLG0.

After a power-on reset the contents will be unpredictable. A read operation can be performed after power-up to keep the register at its default value if required. Contents of this register are meaningful only when UERR_FLG0 is set to 1.

If ECC feature is implemented, the Sequencer FSM clearing the TXFULL flag (after a TXRAM location read out and written to the shift register for transfer) will trigger read-modify-write operation to the RXRAM. Similarly, each time FSM reads a TXRAM to transfer it out, the corresponding RXRAM location is also automatically read to determine the status of the buffer. A double-bit error could be detected during these FSM read operations and result in error address and flags getting captured.

NOTE: Clearing of UERR status and address registers

After completing a memory test sequence, specifically where parity or ECC features are tested, user must read back the status flags in PAR_ECC_STAT and UERRADDRx registers and ensure that they are in normal clear state by reading/writing appropriately. This can be performed before the start of a normal multi-buffer mode transactions as well.

If RAM Parity Check is supported, UERRADDR0[1:0] values will reflect the byte positions of failed byte based on the following scheme to take care of Endianness of memory organization.

	01	10	15:8
	10	01	23:16
	11	00	31:24

NOTE: When ECC is supported, UERRADDR0 will indicate only word address. UERRADDR0[1:0] will always be 00.

28.3.42 RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR)

In multi-buffer mode, if a particular RXRAM location is written by the MibSPI sequencer logic after the completion of a new transfer when that location already contains valid data, the RX_OVR bit will be set to 1 while the data is being written. The RXOVRN_BUF_ADDR register captures the address of the RXRAM location for which a receiver overrun condition occurred.

Table 28-53. RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	RXOVRN_BUF_ADDR	200h-3FCh	Address in RXRAM at which an overwrite occurred. This address value will show only the offset address of the RAM location in the multi-buffer RAM address space. Refer to the device-specific data sheet for the actual absolute address of RXRAM. This word-aligned address can vary from 200h-3FCh. Contents of this register are valid only when any of the INTVECT0 or INTVECT1 and SPIFLG registers show an RXOVRN error vector while in multi-buffer mode. If there are multiple overrun errors, then this register holds the address of first overrun address until it is read. **Note: Reading this register clears the RXOVRN interrupt flag in the SPIFLG register and the TGINTVECTx.** **Note: Receiver overrun errors in multi-buffer mode can be completely avoided by using the SUSPEND until RXEMPTY feature, which can be programmed into each buffer of any TG. However, using the SUSPEND until RXEMPTY feature will make the sequencer wait until the current RXRAM location is read by the VBUS master before it can start the transfer for the same buffer location again. This may affect the overall throughput of the SPI transfer. By enabling the interrupt on RXOVRN in multi-buffer mode, the user can rely on interrupts to know if a receiver overrun has occurred. The address of the overrun in RXRAM is indicated in this RXOVRN_BUF_ADDR register**.

28.3.43 I/O-Loopback Test Control Register (IOLPBKTSTCR)

This register controls test mode for I/O pins. It also controls whether loop-back should be digital or analog. In addition, it contains control bits to induce error conditions into the module. These are to be used only for module testing.

All of the control/status bits in this register are valid only when the IOLPBKTSTENA field is set to Ah.

Table 28-54. I/O-Loopback Test Control Register (IOLPBKTSTCR) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	SCS FAIL FLG		Bit indicating a failure on $\overline{\text{SPICS}}$ pin compare during analog loopback.
		0	Read: No miscompares occurred on any of the eight chip select pins (vs. the internal chip select number CSNR during transfers). Write: No effect.
		1	Read: A comparison between the internal CSNR field and the analog looped-back value of one or more of the $\overline{\text{SPICS}}$ pins failed. A stuck-at fault is detected on one of the $\overline{\text{SPICS}}$ pins. Comparison is done only on the pins that are configured as functional and during transfer operation. Write: This flag bit is cleared.
23-21	Reserved	0	Reads return 0. Writes have no effect.
20	CTRL BITERR		Controls inducing of BITERR during I/O loopback test mode.
		0	Do not interfere with looped-back data.
		1	Induces bit errors by inverting the value of the incoming data during loopback.
19	CTRL DESYNC		Controls inducing of the desync error during I/O loopback test mode.
		0	Do not cause a desync error.
		1	Induce a desync error by forcing the incoming $\overline{\text{SPIENA}}$ pin (if functional) to remain 0 even after the transfer is complete. This forcing will be retained until the kernel reaches the idle state.
18	CTRL PARERR		Controls inducing of the parity errors during I/O loopback test mode.
		0	Do not cause a parity error.
		1	Induce a parity error by inverting the polarity of the parity bit.
17	CTRL TIMEOUT		Controls inducing of the timeout error during I/O loopback test mode.
		0	Do not cause a timeout error.
		1	Induce a timeout error by forcing the incoming $\overline{\text{SPIENA}}$ pin (if functional) to remain 1 when transmission is initiated. The forcing will be retained until the kernel reaches the idle state.

Table 28-54. I/O-Loopback Test Control Register (IOLPBKTSTCR) Field Descriptions (continued)

Bit	Field	Value	Description
16	CTRL DLENERR		Controls inducing of the data length error during I/O loopback test mode.
		0	Do not cause a data-length error.
		1	Induce a data-length error.
			Master mode: The $\overline{\text{SPIENA}}$ pin (if functional) is forced to 1 when the module starts shifting data.
			Slave mode: The incoming $\overline{\text{SPICS}}$ pin (if functional) is forced to 1 when the module starts shifting data.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	IOLPBKSTENA		Module I/O loopback test enable key.
		Ah	Enable I/O loopback test mode.
		All Other Values	Disable I/O loopback test mode.
7-6	Reserved	0	Reads return 0. Writes have no effect.
5-3	ERR SCS PIN		Inject error on chip-select pin number x. The value in this field is decoded as the number of the chip select pin on which to inject an error. During analog loopback, if CTRL SCS PIN ERR bit is set to 1, then the chip select pin selected by this field is forced to the opposite of its value in the CSNR.
		0	Select $\overline{\text{SPICS}}$[0] for injecting error.
		1h	Select $\overline{\text{SPICS}}$[1] for injecting error.
		:	:
		7h	Select $\overline{\text{SPICS}}$[7] for injecting error.
2	CTRL SCS PINERR		Enable the injection of an error on the $\overline{\text{SPICS}}$ pins. The individual $\overline{\text{SPICS}}$ pins can be chosen using the ERR SCS PIN field.
		0	Disable the $\overline{\text{SPICS}}$ error-inducing logic.
		1	Enable the $\overline{\text{SPICS}}$ error-inducing logic.
1	LPBK TYPE		Module I/O loopback type (analog/digital). See Figure 28-31 for the different types of loopback modes.
		0	Enable Digital loopback when IOLPBKTSTENA = 1010.
		1	Enable Analog loopback when IOLPBKTSTENA = 1010.
0	RXP ENA		Enable analog loopback through the receive pin.
			Note: This bit is valid only when LPBK TYPE = 1, which chooses analog loopback mode.
		0	Analog loopback is through the transmit pin.
		1	Analog loopback is through the receive pin.

28.3.44 SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1 for SPIFMT0 and SPIFMT1)

This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT0 and SPIFMT1 registers. For example, EPRESCALE_FMT1(7:0) of EXTENDED_PRESCALE1 and PRESCALE1(7:0) of SPIFMT1 register will always reflect the same contents. Similarly EPRESCALE_FMT0(7:0) and PRESCALE0(7:0) of SPIFMT0 reflect the same contents.

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 28-55. SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26-16	EPRESCALE_FMT1	0-7FFh	EPRESCALE_FMT1. Extended Prescale value for SPIFMT1. EPRESCALE_FMT1 determines the bit transfer rate of data format 1 if the SPI/MibSPI is the network master. EPRESCALE_FMT1 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT1 **does not need** to be configured. These EPRESCALE_FMT1(7:0) bits and PRESCALE1 bits of SPIFMT1 register will point to the same physically implemented register. The clock rate for data format 1 can be calculated as: $BR_{Format1}$ = VCLK / (EPRESCALE_FMT1 + 1) Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT1(15:8). Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE1(26:16) or SPIFMT1(15:8) register. **Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT1 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE1 field of SPIFMT1 will automatically clear EPRESCALE_FMT1(10:8) bits to 000 so that the integrity of PRESCALE value is maintained.**
15-11	Reserved	0	Reads return 0. Writes have no effect.

28.3.48 Single-Bit Error Address Register - RXRAM (SBERRADDR1)

Figure 28-84. Single-Bit Error Address Register - RXRAM (SBERRADDR1) [offset = 148h]

LEGEND: R = Read only; RC = Read to clear; -*n* = value after reset

Table 28-59. Single-Bit Error Address Register - RXRAM (SBERRADDR1) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	Reads return 0. Writes have no effect.
10-0	SBERRADDR1		This register holds the address of the RAM location when a single-bit error is generated by SECDED block while reading the MibSPI (Receive) RXRAM. This error address is frozen from being updated until it is read by the VBUS host. Reading this register clears its contents to the default value. The default value is 400h if Extended Buffer feature is enabled; else, it is 200h. Writes to this register are ignored.

NOTE: SBERRADDR1 values

The offset address of RXRAM can vary from 200h-3FFh, if EXTENDED_BUF mode is disabled. If the EXTENDED_BUF mode is enabled, the offset address can vary from 400h-7FFh.

The register does not clear its contents during and after any of the module-level resets, System-level resets, or even Power-on Reset.

NOTE: A Read to SBERRADDR1 Register will clear the SBE_FLG1 in PAR_ECC_STAT register. However, in emulation mode (VBUSP_EMUDBG = 1), the read to SBERRADDR1 register does not clear the corresponding SBE_FLG1.

After a power-on reset the contents will be unpredictable. A read operation can be performed after power-up to keep the register at its default value if required. Contents of this register are meaningful only when SBE_FLG1 is set to 1.

If ECC feature is implemented, the Sequencer FSM clearing the TXFULL flag (after a TXRAM location read out and written to the shift register for transfer) will trigger read-modify-write operation to the RXRAM. Similarly, each time FSM reads a TXRAM to transfer it out, the corresponding RXRAM location is also automatically read to determine the status of the buffer. A single-bit error could be detected during these FSM read operations and result in error address and flags getting captured.

NOTE: Clearing of SBERR status and address registers

After completing a memory test sequence, specifically where ECC features are tested, user must read back the status flags in ECC_STAT and SBERRADDRx registers and ensure that they are in normal clear state by reading/writing appropriately. This can be performed before the start of a normal multi-buffer mode transactions as well.

NOTE: When ECC is supported, SBERRADDR1 will indicate only word address. SBERRADDR1[1:0] will always be 00.

Copyright © 2018, Texas Instruments Incorporated

28.3.49 Single-Bit Error Address Register - TXRAM (SBERRADDR0)

Figure 28-85. Single-Bit Error Address Register - TXRAM (SBERRADDR0) [offset = 14Ch]

31	16
Reserved	
R-0	

15	11	10	0
Reserved		SBERRADDR0	
R-0		RC-0	

LEGEND: R = Read only; RC = Read to clear; -*n* = value after reset

Table 28-60. Single-Bit Error Address Register - TXRAM (SBERRADDR0) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	Reads return 0. Writes have no effect.
10-0	SBERRADDR0		This register holds the address when a single-bit error is generated from SECDED block while reading the MibSPI (Transmit) TXRAM. The TXRAM can be read either by CPU or by the MibSPI Sequencer logic for transmission. This error address is frozen from being updated until it is read by the VBUSP host. Reading this register clears its contents to the default value of 0x000. Writes to this register are ignored.

NOTE: SBERRADDR0 values

The offset address of TXRAM can vary from 000h-1FFh, if EXTENDED_BUF mode is disabled. If the EXTENDED_BUF mode is enabled, the offset address can vary from 000h-3FFh.

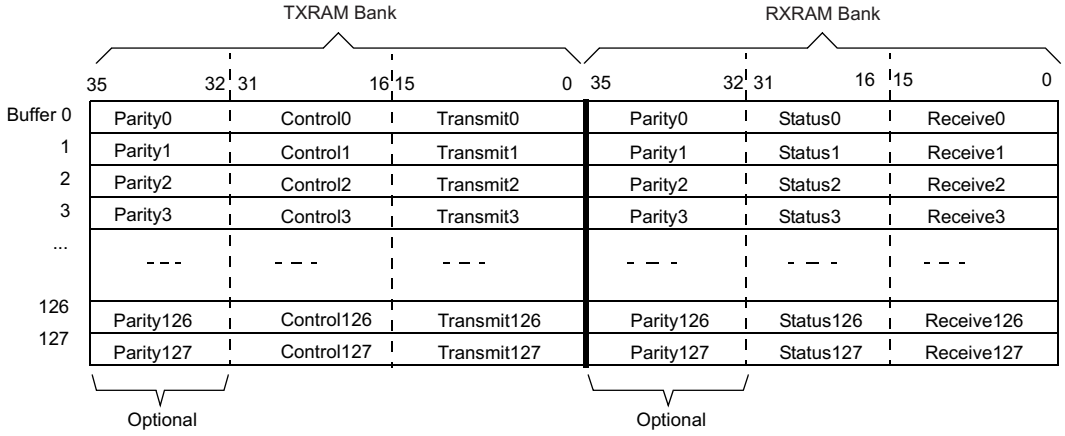
The register does not clear its contents during and after any of the module-level resets, System-level resets, or even Power-on Reset. A Read operation to this register clears its contents to all 0s.

NOTE: A read to SBERRADDR0 register will clear the SBE_FLG0 in PAR_ECC_STAT register. However, in emulation mode (VBUSP_EMUDBG = 1), the read to SBERRADDR0 register does not clear the corresponding SBE_FLG0.

After a power-on reset the contents of this register will be unpredictable. So, a read operation can be performed after power-up to clear its contents if required. Contents of this register are meaningful only when SBE_FLG0 is set to 1.

NOTE: Clearing of SBERR status and address registers

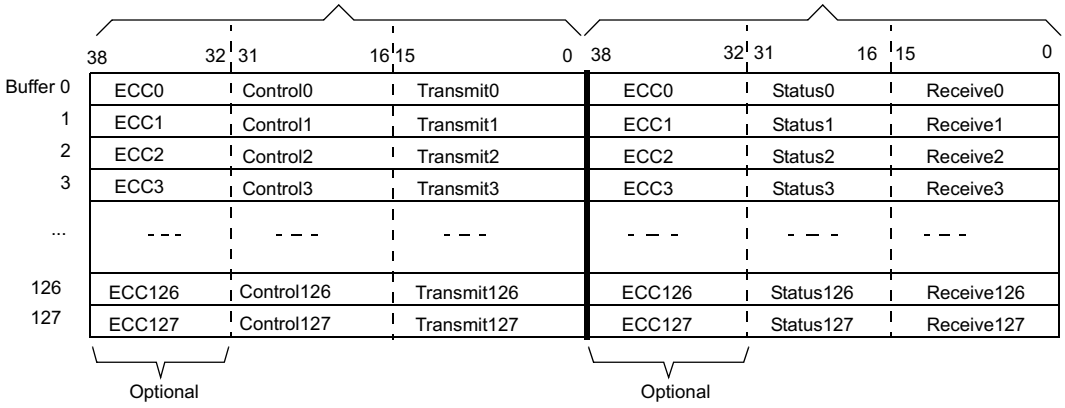
After completing a memory test sequence, specifically where ECC features are tested, user must read back the status flags in ECC_STAT and SBERRADDRx registers to ensure that they are in normal clear state by reading/writing appropriately. This can be performed before the start of a normal multi-buffer mode transactions as well.



NOTE: When ECC is supported, SBERRADDR0 will indicate only word address. SBERRADDR0[1:0] will always be 00.

Copyright © 2018, Texas Instruments Incorporated

28.4 Multi-buffer RAM



The multi-buffer RAM comprises of all buffers, which can be configured identically. The multi-buffer RAM contains two banks of up to128/256 words of 32 bits for a maximum configuration, one each for TXRAM (replicating the SPIDAT1 register) and RXRAM (replicating the SPIBUF register). The buffers can be partitioned into multiple transfer groups, each containing a variable number of buffers. Each of the buffers can be sub-divided into a 16-bit transmit field, a 16-bit receive field, a 16-bit control field, and a 16-bit status field. A 4-bit parity field per word is also included in each RAM bank, as shown in Figure 28-86. If ECC support is implemented for RAM fault detection, then a 7-bit ECC field per word is also included in each RAM bank, as shown in Figure 28-87.

Figure 28-86. Multi-buffer RAM Configuration When Parity Check is Supported

Depth will be up to 256 buffers, if EXTENDED_BUF feature is implemented.

Figure 28-87. Multi-buffer RAM Configuration When ECC Check is Supported

Depth will be up to 256 buffers, if EXTENDED_BUF feature is implemented.

All fields can be read and written with 8-bit, 16-bit, or 32-bit accesses.

The transmit fields can be written and read in the address range 000h to 1FFh. The transmit words contain data and control fields.

The receive RAM fields are read-only and can be accessed through the address range 200h to 3FCh. The receive words contain data and status fields.

The chip select number bit field CSNR[7:0] of the control field for a given word is mirrored into the corresponding receive-buffer status field after transmission.

The Parity is automatically calculated and copied to Parity location

Copyright © 2018, Texas Instruments Incorporated

NOTE: Refer to the specific device datasheet for the actual number of transmit and receive buffers.

Write to unimplemented buffer is overwriting the corresponding implemented buffer. In MIBSPI, if the RAM SIZE specified is 32 buffers, write to 33rd buffer overwrites 1st buffer, write to 34th buffer overwrites 2nd buffer, and so on.

28.4.1 Multi-buffer RAM Auto Initialization

When the MIBSPI is out of reset mode, auto initialization of multi-buffer RAM starts. The application code must check for BUFINITACTIVE bit to be 0 (multi-buffer RAM initialization is complete) before configuring multi-buffer RAM.

Besides the default auto initialization after reset, the auto-initialization sequence can also be done by:

1. Enable the global hardware memory initialization key by programming a value of 1010b to the bits [3:0] of the MINITGCR register of the System module.
2. Set the control bit for the multi-buffer RAM in the MSINENA System module register. This bit is device-specific for each memory that support auto-initialization. Please refer to the device datasheet to identify the control bit for the multi-buffer RAM. This starts the initialization process. The BUFINITACTIVE bit will get set to reflect that the initialization is ongoing.
3. When the memory initialization is completed, the corresponding status bit in the MINISTAT register will be set. Also, the BUFINITACTIVE bit will get cleared.
4. Disable the global hardware memory initialization key by programming a value of 0101 to the bits [3:0] of the MINITGCR register of the System module.

Please refer to the Architecture User Guide for more details on the memory auto-initialization process.

NOTE: During Auto Initialization process, all the multi-buffer mode registers (except MIBSPIE) will be reset to their default values. So, it should be ensured that Auto Initialization is completed before configuring the multi-buffer mode register.

28.4.2 Multi-buffer RAM Register Summary

This section describes the multi-buffer RAM control and transmit-data fields of each word of TXRAM, and the status and receive-data fields of each word of RXRAM. The base address for multi-buffer RAM is FF0E 0000h for MibSPI1 RAM, FF08 0000h for MibSPI2 RAM, FF0C 000h for MibSPI3 RAM, FF06 0000h for MibSPI4 RAM, and FF0A 0000h for MibSPI5 RAM.

Table 28-61. Multi-buffer RAM Register

Offset	Acronym	Register Description	Section
Base + 0h-1FFh	TXRAM	Multi-buffer RAM Transmit Data Register	Section 28.4.3
Base + 200h-3FFh	RXRAM	Multi-buffer RAM Receive Buffer Register	Section 28.4.4

28.4.3 Multi-buffer RAM Transmit Data Register (TXRAM)

Each word of TXRAM is a transmit-buffer register.

NOTE: Writing to only the control fields, bits 28 through 16, does not initiate any SPI transfer in master mode. This feature can be used to set up SPICLK phase or polarity before actually starting the transfer by only updating the DFSEL bit field to select the required phase and polarity combination.

TXDATA
R/W-0

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 28-62. Multi-buffer RAM Transmit Data Register (TXRAM) Field Descriptions

Bit	Field	Value	Description
31-29	BUFMODE		Specify conditions that are recognized by the sequencer to initiate transfers of each buffer word. When one of the "skip" modes is selected, the sequencer checks the buffer status every time it reads from this buffer. If the current buffer status (TXFULL, RXEMPTY) does not match, the buffer is skipped without a data transfer. When one of the "suspend" modes is selected, the sequencer checks the buffer status when it reads from this buffer. If TXFULL and/or RXEMPTY do not match, the sequencer waits until a match occurs. No data transfer is initiated until the status condition of this buffer changes.
		0	**disabled.** The buffer is disabled.
		1h	**skip single-transfer mode.** Skip this buffer until the corresponding TXFULL flag is set (new transmit data is available).
		2h	**skip overwrite-protect mode.** Skip this buffer until the corresponding RXEMPTY flag is set (new receive data can be stored in RXDATA without data loss).
		3h	**skip single-transfer overwrite-protect mode**. Skip this buffer until both of the corresponding TXFULL and RXEMPTY flags are set. (new transmit data available and previous data received by the host).
		4h	**continuous mode.** Initiate a transfer each time the sequencer checks this buffer. Data words are retransmitted if the buffer has not been updated. Receive data is overwritten, even if it has not been read.
		5h	**suspend single-transfer mode.** Suspend-to-wait until the corresponding TXFULL flag is set (the sequencer stops at the current buffer until new transmit data is written in the TXDATA field).
		6h	**suspend overwrite-protect mode.** Suspend-to-wait until the corresponding RXEMPTY flag is set (the sequencer stops at the current buffer until the previously-received data is read by the host.
		7h	**suspend single-transfer overwrite-protect mode.** Suspend-to-wait until the corresponding TXFULL and RXEMPTY flags are set (the sequencer stops at the current buffer until new transmit data is written into the TXDATA field and the previously-received data is read by the host).
28	CSHOLD		Chip select hold mode. The CSHOLD bit is supported in master mode only, it is ignored in slave mode. CSHOLD defines the behavior of the chip select line at the end of a data transfer.
		0	The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.
		1	The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes.

Table 28-62. Multi-buffer RAM Transmit Data Register (TXRAM) Field Descriptions (continued)

Bit	Field	Value	Description
27	LOCK		Lock two consecutive buffer words. Do not allow interruption by TG's with higher priority.
		0	Any higher-priority TG can begin at the end of the current transaction.
		1	A higher-priority TG cannot occur until after the next unlocked buffer word is transferred.
26	WDEL		Enable the delay counter at the end of the current transaction.
			Note: The WDEL bit is supported in master mode only. In slave mode, this bit will be ignored.
		0	No delay will be inserted. However, the $\overline{\text{SPICS}}$ pins will still be de-activated for at least for 2VCLK cycles if CSHOLD = 0.
			Note: The duration for which the $\overline{\text{SPICS}}$ pin remains deactivated also depends upon the time taken to supply a new word after completing the shift operation (in compatibility mode). If TXBUF is already full, then the $\overline{\text{SPICS}}$ pin will be deasserted for at least two VCLK cycles (if WDEL = 0).
		1	After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The $\overline{\text{SPICS}}$ pins will be de-activated for at least (WDELAY + 2) × VCLK_Period duration.
25-24	DFSEL		Data word format select.
		0	Data word format 0 is selected.
		1h	Data word format 1 is selected.
		2h	Data word format 2 is selected.
		3h	Data word format 3 is selected.
23-16	CSNR	0-FFh	Chip select (CS) number. CSNR defines the chip select pins that will be activated during the data transfer. CSNR is a bit-mask that controls all chip select pins. See Table 28-63.
			Note: If your MibSPI has less than 8 chip select pins, all unused upper bits will be 0. For example, MiBSPI3 has 6 chip select pins, if you write FFh to CSNR, the actual number stored in CSNR is 3Fh.
15-0	TXDATA	0-7FFFh	Transfer data. When written, these bits are copied to the shift register if it is empty. If the shift register is not empty, then they are held in TXBUF.
			SPIEN must be set to 1 before this register can be written to. Writing a 0 to SPIEN forces the lower 16 bits of TXDATA to 0.
			A write to this register (or to the TXDATA field only) drives the contents of the CSNR field on the $\overline{\text{SPICS}}$ pins, if the pins are configured as functional pins (automatic chip select, see Section 28.2.1).
			When this register is read, the contents of TXBUF, which holds the latest data written, will be returned.
			Note: Regardless of the character length, the transmit data should be right-justified before writing to the SPIDAT1 register.

28.4.4 Multi-buffer RAM Receive Buffer Register (RXRAM)

Each word of RXRAM is a receive-buffer register.

R/W-0							

LEGEND: R = Read only; R/W = Read/Write; C = Clear; S = Set; -*n* = value after reset

Table 28-64. Multi-buffer Receive Buffer Register (RXRAM) Field Descriptions

Bit	Field	Value	Description
31	RXEMPTY		Receive data buffer empty. When the host reads the RXDATA field or the entire RXRAM register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into RXDATA, and the RXEMPTY flag is cleared.
		0	New data has been received and copied into RXDATA.
		1	No data has been received since the last read of RXDATA.
			This flag gets set to 1 under the following conditions: • Reading the RXDATA field of the RXRAM register. • Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG). Write-clearing the RXINTFLG bit before reading RXDATA indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA field of RXRAM (or the entire register).
30	RXOVR		Receive data buffer overrun. When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to RXRAM; the contents of RXRAM are overwritten only after it is read by the Peripheral (VBUSP) master (CPU, DMA, or other host processor). If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVECTx shows the RXOVRN condition. Two read operations from the RXRAM register are required to reach the overwritten buffer word (one to read RXRAM, which then transfers RXDATA into RXRAM for the second read). **Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.** **Note: A special condition under which RXOVR flag gets set.If both RXRAM and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.**
		0	No receive data overrun condition occurred since last read of the data field.
		1	A receive data overrun condition occurred since last read of the data field.
29	TXFULL		Transmit data buffer full. This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag.
		0	The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.
		1	The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.

Copyright © 2018, Texas Instruments Incorporated

Table 28-64. Multi-buffer Receive Buffer Register (RXRAM) Field Descriptions (continued)

Bit	Field	Value	Description
28	BITERR		Bit error. There was a mismatch of internal transmit data and transmitted data.
			Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		0	No bit error occurred.
		1	A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.
27	DESYNC		Desynchronization of slave device. This bit is valid in master mode only.
			The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus $t_{T2EDELAY}$. If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.
			Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always guaranteed to be for the current buffer.
			Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		0	No slave desynchronization is detected.
		1	A slave device is desynchronized.
26	PARITYERR		Parity error. The calculated parity differs from the received parity bit.
			If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set.
			Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		0	No parity error is detected.
		1	A parity error occurred.
25	TIMEOUT		Time-out because of non-activation of $\overline{\text{SPIENA}}$ pin.
			The SPI generates a time-out when the slave does not respond in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition, the TIMEOUT flag in the status field of the corresponding buffer and in the SPI Flag Register (SPIFLG) is set.
			This bit is valid only in master mode.
			Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		0	No $\overline{\text{SPIENA}}$ pin time-out occurred.
		1	An $\overline{\text{SPIENA}}$ signal time-out occurred.
24	DLENERR		Data length error flag.
			Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		0	No data-length error occurred.
		1	A data length error occurred.
23-16	LCSNR	0-FFh	Last chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It contains the chip select number that was activated during the last word transfer.
15-0	RXDATA	0-FFFFh	SPI receive data. This is the received word, transferred from the receive shift-register at the end of a transfer. Regardless of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.

28.5 Parity\ECC Memory

Parity/ECC portion of multi-buffer RAM is not accessible by the CPU during normal operating modes. However each read or write operation to the Control/Data/Status portion of the multi-buffer RAM causes reads/writes to the parity/ECC portion as well.

- Each write to the multi-buffer RAM (either from the VBUS interface or by the MibSPI itself) causes a write operation to the Parity/ECC portion of RAM simultaneously to update the equivalent parity/ECC bits.
- Each read operation from the multi-buffer RAM (either from the VBUS interface or by the MibSPI itself) causes a read operation from the Parity/ECC portion of the RAM for parity/ECC comparison purpose.
- Reads/Writes to multi-buffer RAM could either be caused by any CPU/DMA accesses or by the Sequencer logic of MibSPI itself.

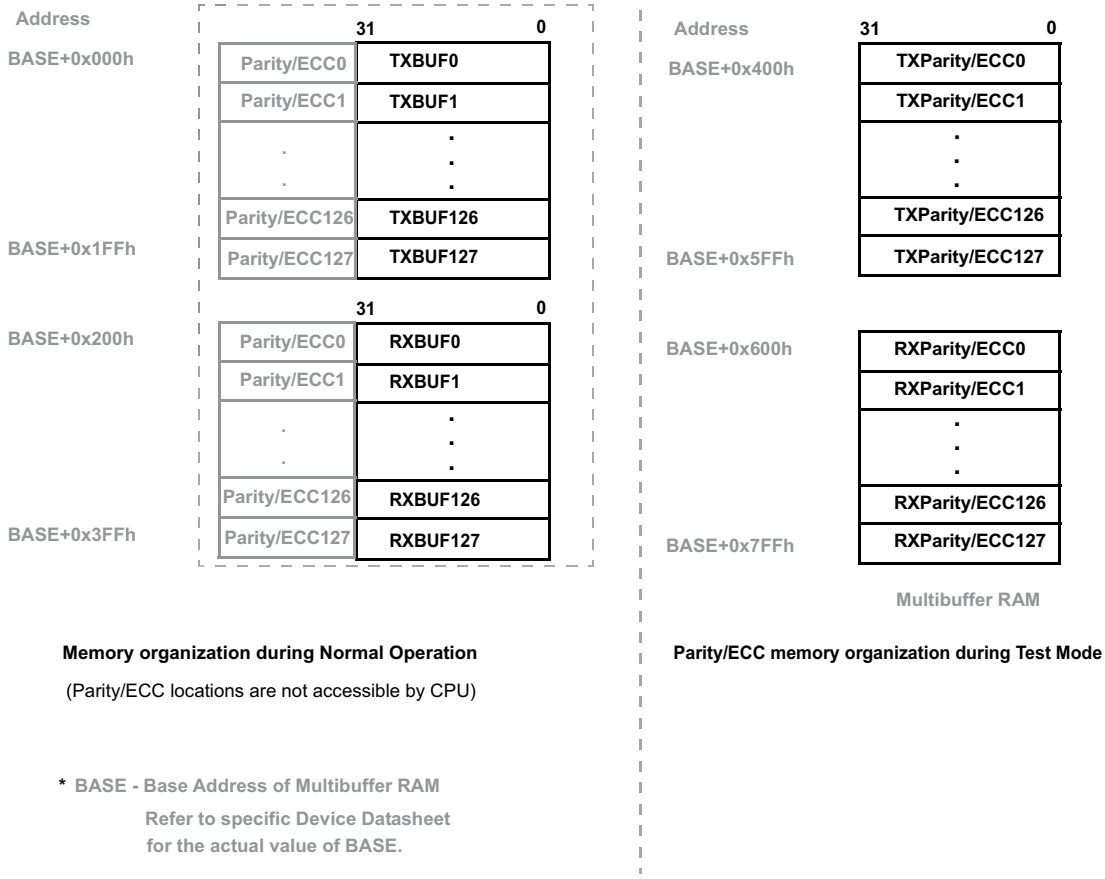
For testing the Parity/ECC portion of the multi-buffer RAM that is a 4-bit or 7-bit field per word address, a separate parity/ECC memory test mode is available. The parity memory test mode can be enabled and disabled by the PTESTEN bit in PAR_ECC_CTRL register and the ECCDIAG_EN bit in ECCDIAG_CTRL register.

During the parity test mode, the parity locations are addressable at the address between RAM_BASE_ADDR + 0x400h and RAM_BASE_ADDR + 0x7FFh. Each location corresponds, sequentially, to each TXRAM word, then to each RXRAM word. See Figure 28-90 for a diagram of the memory map of parity memory during normal operating mode and during parity test mode while EXTENDED_BUF mode is disabled or the feature is not implemented. See Figure 28-91 for a diagram of the memory map of parity memory during normal operating mode and during parity test mode while EXTENDED_BUF mode is enabled.

During Parity/ECC test mode, after writing the Data/Control portion of the RAM, the Parity/ECC locations can be written with wrong parity/ECC bits to intentionally cause Parity/ECC Errors.

See the device-specific data sheet to get the actual base address of the multi-buffer RAM.

NOTE: The RX_RAM_ACCESS bit can also be set to 1 during the Parity/ECC Test mode to be able to write to RXRAM locations for test purpose. Both Parity/ECC bits testing and RXRAM testing can be done together.



There are 4 bits of parity corresponding to each of the 32-bit multi-buffer locations. Individual bits in the parity memory are byte-addressable in parity test mode. See the example in Section 28.5.1 for further details.

If ECC is enabled, there are 7 ECC-bits corresponding to each of the 32-bit multi-buffer locations. See the example in Section 28.5.1 for further details.

NOTE: Polarity of the parity (odd/even) varies by device. In some devices, a control register in the system module can be used to select odd or even parity.

28.5.1 Example of Parity Memory Organization

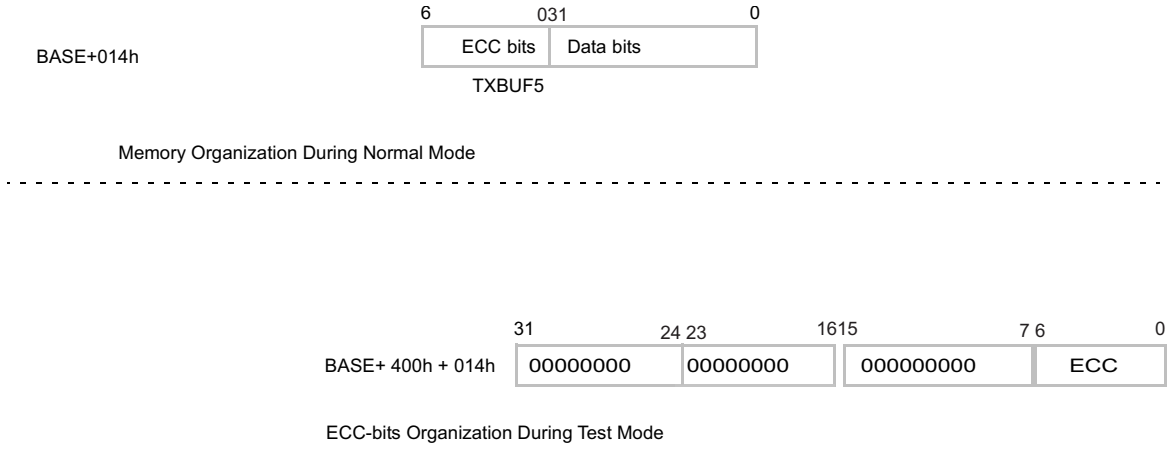
Suppose TXBUF5 (6th location in TXRAM) in the multi-buffer RAM is written with a value of A001_AA55. If the polarity of the parity is set to odd, the corresponding parity location parity5 will get updated with equivalent parity of 1011 in its field.

During parity-memory test mode, these bits can be individually byte addressed. The return data will be a byte adjusted with actual parity bit in the LSB of the byte. If a word is read from the word-boundary address of parity locations, then each bit of the 4-bit parity is byte-adjusted and a 32-bit word is returned. 0s will be padded into the parity bits to get each byte. See Figure 28-92 for a diagram.

Figure 28-92. Example of Memory-Mapped Parity Locations During Test Mode

NOTE: Read Access to Parity Memory Locations

Parity memory locations can be read even without entering into parity memory test mode. Their address remains as in memory test mode. It is only to enter parity-memory test mode to enable write access to the parity memory locations.



Copyright © 2018, Texas Instruments Incorporated

28.5.2 Example of ECC Memory Organization

Suppose TXBUF5 (6th location in TXRAM portion) in the multi-buffer RAM is written with a value of A001_AA55, then the corresponding ECC-bits will be updated in ECC location.

The ECC bits can be accessed by user, when Memory Test mode is enabled and additionally diagnostic mode is also enabled. The actual ECC bits will be aligned as shown in Figure 28-93.

Figure 28-93. Example of ECC Bit Locations During Test Mode

NOTE: Access to ECC locations

ECC locations can be read/write only when Parity Memory Test mode and diagnostic mode is enabled

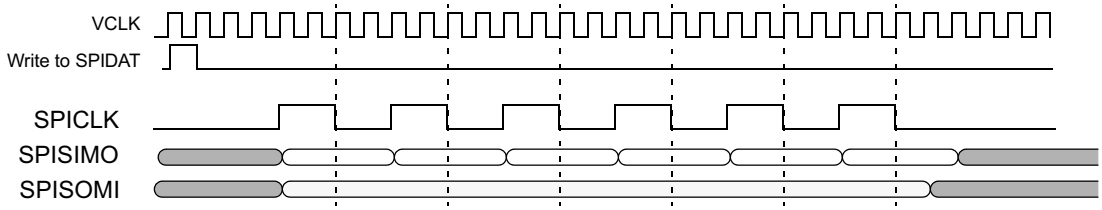
28.6 MibSPI Pin Timing Parameters

The pin timings of SPI can be classified based on its mode of operation. In each mode, different configurations like Phase & Polarity affect the pin timings.

The pin directions are based on the mode of operation.

Master mode SPI:

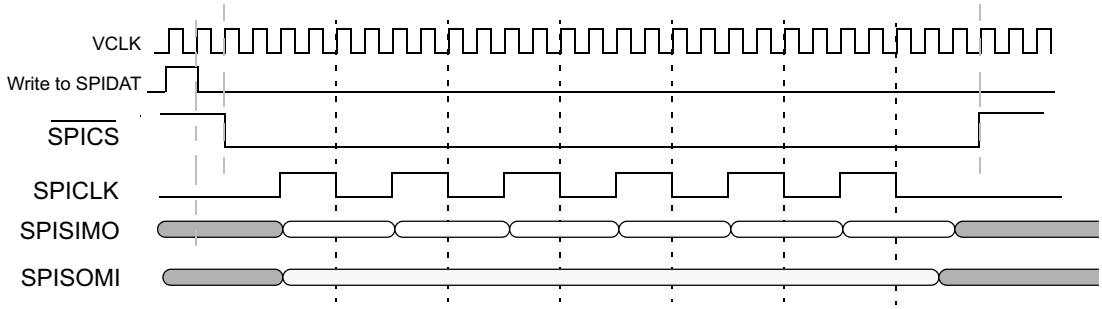
- SPICLK (SPI Clock) - Output
- SPISIMO (SPI Slave In Master Out) - Output
- $\overline{\text{SPICS}}$ (SPI Slave Chip Selects) - Output
- SPISOMI (SPI Slave Out Master In) - Input
- $\overline{\text{SPIENA}}$ (SPI slave ready Enable) - Input



Slave mode SPI:

- SPICLK - Input
- SPISIMO - Input
- $\overline{\text{SPICS}}$ - Input
- SPISOMI - Output
- $\overline{\text{SPIENA}}$ - Output

NOTE: All the following timing diagrams are with Phase = 0 and Polarity = 0, unless explicitly stated otherwise.



28.6.1 Master Mode Timings for SPI/MibSPI

28.6.3 Master Mode Timing Parameter Details

In case of Master, the module drives out SPICLK. It also drives out the Transmit data on SPISIMO with respect to its internal SPICLK. In case of Master mode, the RX data on the SPISOMI pin is registered with respect to SPICLK received through the input buffer from the I/O pad.

If the chip select pin is functional, then the Master will drive out the $\overline{\text{SPICS}}$ pins before starting the SPICLK. If the $\overline{\text{SPIENA}}$ pin is functional, then the Master will wait for an active low from the Slave on the input pin to start the SPICLK.

28.6.4 Slave Mode Timing Parameter Details

In case of Slave mode, the module will drive only the SPISOMI and $\overline{\text{SPIENA}}$ pins. All other pins are inputs to it. The RX data on the SPISIMO pin will be registered with respect to the SPICLK pin. The Slave will use the $\overline{\text{SPICS}}$ pin to drive out the $\overline{\text{SPIENA}}$ pin if both are functional. If 4-pin with $\overline{\text{SPIENA}}$ is configured, then the Slave will drive out an active-low signal on the $\overline{\text{SPIENA}}$ pin when new data is written to the TX Shift Register. Irrespective of 4-pin with $\overline{\text{SPIENA}}$ or 5-pin configuration, the Slave will deassert the $\overline{\text{SPIENA}}$ pin after the last bit is received. If ENABLE_HIGHZ (SPIINT0.24) bit is 0, the de-asserted value of the $\overline{\text{SPIENA}}$ pin will be 1. Otherwise, it will depend upon the internal pull up or pull down resistor (if implemented) depending upon the Specification of the Chip.

Serial Communication Interface (SCI)/ Local Interconnect Network (LIN) Module

This chapter describes the serial communication interface (SCI) / local interconnect network (LIN) module. The SCI/LIN is compliant to the LIN 2.1 protocol specified in the *LIN Specification Package*. This module can be configured to operate in either SCI (UART) or LIN mode.

NOTE: This chapter describes a superset implementation of the LIN/SCI module that includes features and functionality that require DMA. Since not all devices have DMA capability, consult your device-specific datasheet to determine applicability of these features and functions to your device being used.

Copyright © 2018, Texas Instruments Incorporated

29.1 Introduction and Features

The SCI/LIN module can be programmed to work either as an SCI or as a LIN. The core of the module is an SCI. The SCI's hardware features are augmented to achieve LIN compatibility.

The SCI module is a universal asynchronous receiver-transmitter that implements the standard nonreturn to zero format. The SCI can be used to communicate, for example, through an RS-232 port or over a K-line.

The LIN standard is based on the SCI (UART) serial data link format. The communication concept is single-master/multiple-slave with a message identification for multi-cast transmission between any network nodes.

Throughout the chapter Compatibility Mode refers to SCI Mode functionary of SCI/LIN Module. Section 29.2 explains about the SCI functionality and Section 29.3 explains about the LIN functionality. Though the registers are common for LIN and SCI, the register descriptions has notes to identify the register/bit usage in different modes.

29.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard nonreturn to zero (NRZ) format
- Double-buffered receive and transmit functions in compatibility mode
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous or isosynchronous communication modes
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports 2^{24} different baud rates provide high accuracy baud rate selection
- At 100-MHz peripheral clock, 3.125 Mbits/s is the Max Baud Rate achievable
- Capability to use Direct Memory Access (DMA) for transmit and receive data
- Five error flags and Seven status flags provide detailed information regarding SCI events
- Two external pins: LINRX and LINTX
- Multi-buffered receive and transmit units

NOTE: SCI/LIN module does not support UART hardware flow control. This feature can be implemented in software using a general purpose I/O pin.

Copyright © 2018, Texas Instruments Incorporated

29.1.2 LIN Features

The following are the features of the LIN module:

- Compatibility with LIN 1.3, 2.0, and 2.1protocols
- Configurable Baud Rate up to 20 Kbits/s
- Two external pins: LINRX and LINTX.
- Multi-buffered receive and transmit units
- Identification masks for message filtering
- Automatic master header generation
  - Programmable synchronization break field
  - Synchronization field
  - Identifier field
- Slave automatic synchronization
  - Synchronization break detection
  - Optional baud rate update
  - Synchronization validation
- 2^{31} programmable transmission rates with 7 fractional bits
- Wakeup on LINRX dominant level from transceiver
- Automatic wakeup support
  - Wakeup signal generation
  - Expiration times on wakeup signals
- Automatic bus idle detection
- Error detection
  - Bit error
  - Bus error
  - No-response error
  - Checksum error
  - Synchronization field error
  - Parity error
- Capability to use Direct Memory Access (DMA) for transmit and receive data.
- 2 Interrupt lines with priority encoding for:
  - Receive
  - Transmit
  - ID, error, and status
- Support for LIN 2.0 checksum
- Enhanced synchronizer finite state machine (FSM) support for frame processing
- Enhanced handling of extended frames
- Enhanced baud rate generator
- Update wakeup/go to sleep

29.1.3 Block Diagram

The SCI/LIN module contains core SCI block with added sub-blocks to support LIN protocol.

Three Major components of the SCI Module are:

- Transmitter
- Baud Clock Generator
- Receiver

Transmitter (TX) contains two major registers to perform the double- buffering:

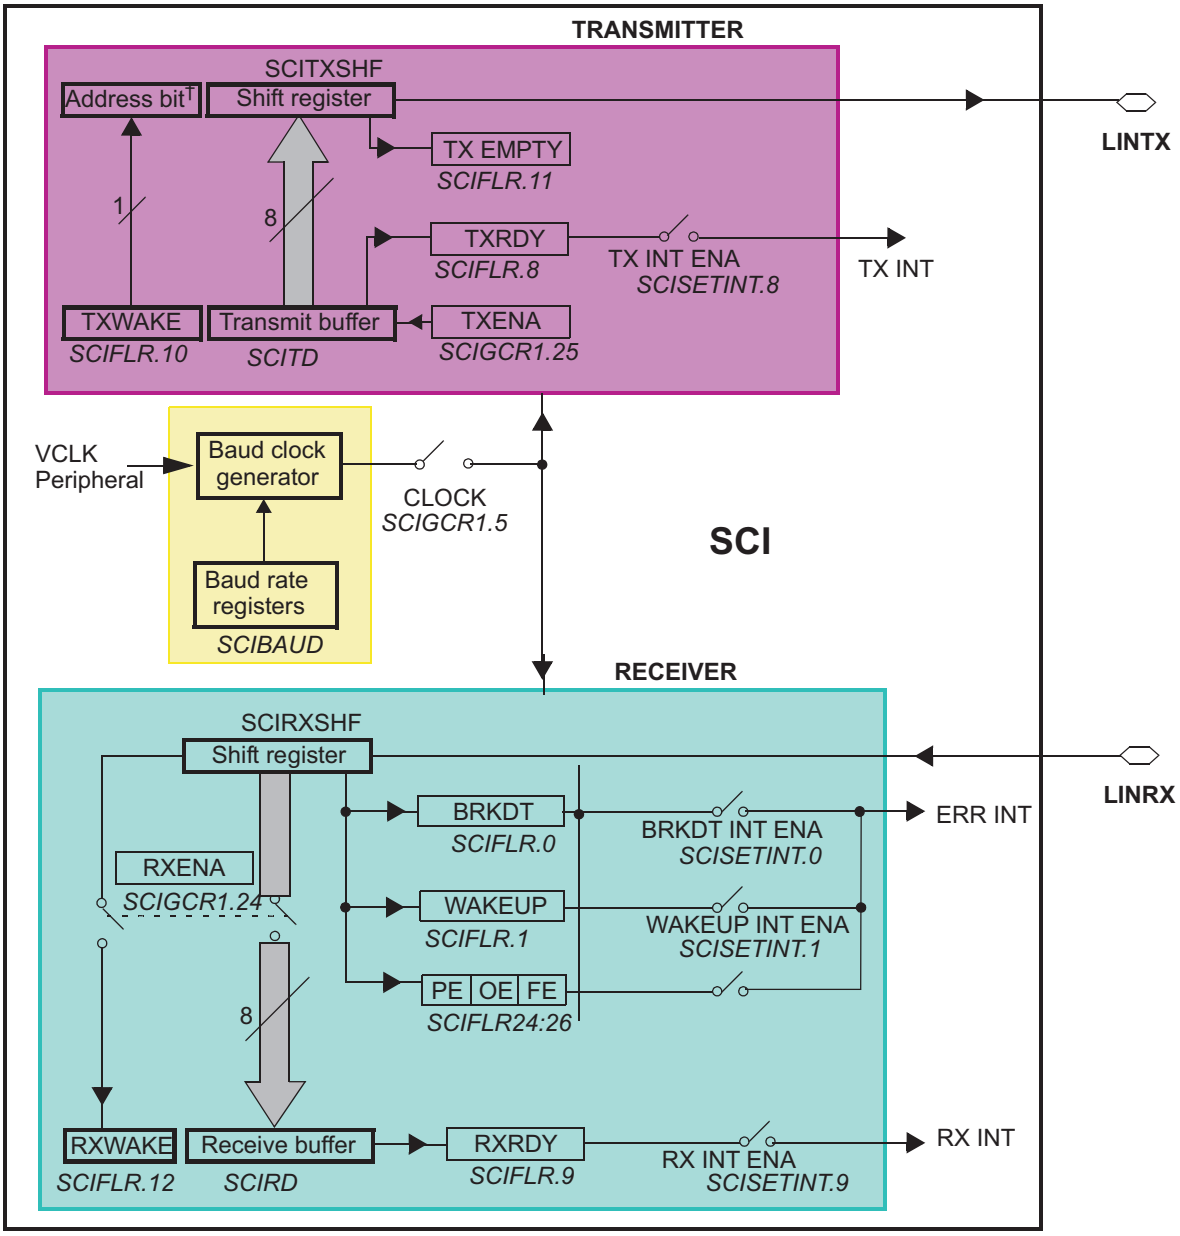
- The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
- The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the LINTX pin, one bit at a time.

Baud Clock Generator

- A programmable baud generator produces either a baud clock scaled from VBUSP CLK.

Receiver (RX) contains two major registers to perform the double- buffering:

- The receiver shift register (SCIRXSHF) shifts data in from the LINRX pin one bit at a time and transfers completed data into the receive data buffer.
- The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register



The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. Figure 29-1 shows the detailed SCI block diagram.

The SCI/LIN module is based on the standalone SCI with the addition of an error detector (parity calculator, checksum calculator, and bit monitor), a mask filter, a synchronizer, and a multi-buffered receiver and transmitter. The SCI interface, the DMA control subblocks and the baud generator are modified as part of the hardware enhancements for LIN compatibility. Figure 29-2 shows the SCI/LIN block diagram.

29.2 SCI

29.2.1 SCI Communication Formats

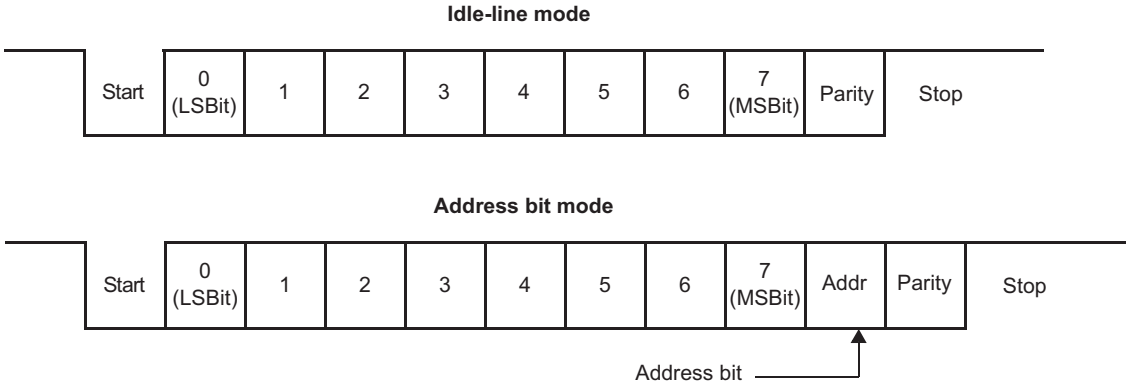
The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI/LIN are user configurable. The list below describes these configuration options:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

29.2.1.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits



The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in Figure 29-3.

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in Figure 29-3 have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in Figure 29-3 use one stop bit per frame.

Figure 29-3. Typical SCI Data Frame Formats

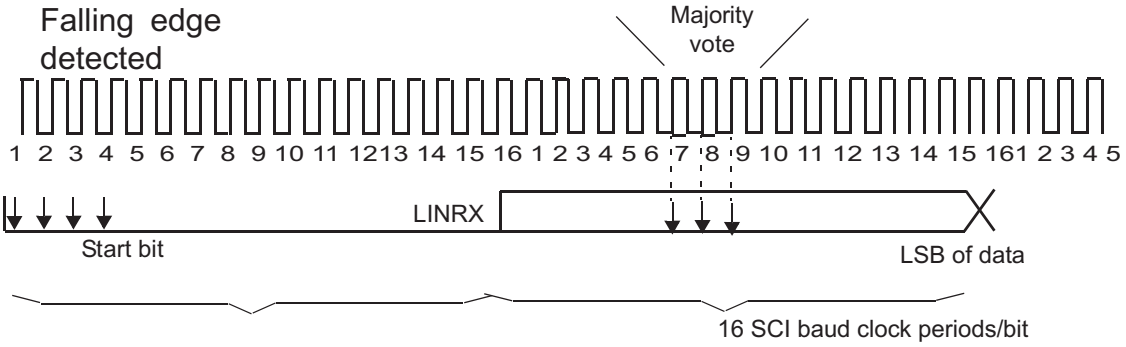
29.2.1.2 SCI Timing Mode

The SCI can be configured to use asynchronous or isosynchronous timing using TIMING MODE bit in SCIGCR1 register.

29.2.1.2.1 Asynchronous Timing Mode

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver- transmitter (UART) protocol.



In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the LINRX pin are of logic level 0. As soon as a falling edge is detected on LINRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects LINRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the LINRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises. Figure 29-4 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the LINTX pin. The transmitter then holds the current bit value on LINTX for 16 SCI baud clock periods.

Figure 29-4. Asynchronous Communication Bit Timing

29.2.1.2.2 Isosynchronous Timing Mode

In isosynchronous timing mode, each bit in a frame has a duration of exactly 1 baud clock period and therefore consists of a single sample. With this timing configuration, the transmitter and receiver are required to make use of the SCICLK pin to synchronize communication with other SCI. **This mode is not supported on this device because SCICLK pin is not available.**

29.2.1.3 SCI Baud Rate

The SCI/LIN has an internally generated serial clock determined by the peripheral VCLK and the prescalers P and M in this register. The SCI uses the 24-bit integer prescaler P value in the BRS register to select the required baud rates. The additional 4-bit fractional divider M refines the baud rate selection.

Copyright © 2018, Texas Instruments Incorporated

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$SCICLK\ Frequency = \frac{VCLK\ Frequency}{P + 1 + \frac{M}{16}}$$

$$Asynchronous\ baud\ value = \frac{SCICLK\ Frequency}{16}$$

For P = 0,

$$Asynchronous\ baud\ value = \frac{VCLK\ Frequency}{32} \quad (42)$$

29.2.1.3.1 Superfractional Divider, SCI Asynchronous Mode

The superfractional divider is available in SCI asynchronous mode (idle-line and address-bit mode). Building on the 4-bit fractional divider M (BRS[27:24]), the superfractional divider uses an additional 3-bit modulating value (see Table 29-2). The bits with a 1 in the table will have an additional VCLK period added to their T_{bit}. If the character length is more than 10, then the modulation table will be a rolled-over version of the original table (Table 29-1), as shown in Table 29-2.

The baud rate will vary over a data field to average according to the BRS[30:28] value by a "**d**" fraction of the peripheral internal clock: **0<d<1.** See Figure 29-5 for a simple Average "d' calculation based on "U" value (BRS[30:28]).

The instantaneous bit time is expressed in terms of T_{VCLK} as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK} \quad (43)$$

For P = 0 $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of T_{VCLK} as follows:

For all P other than 0, and all M and d (0<d<1),

$$T^{a}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK} \quad (44)$$

For P = 0 $T_{bit} = 32T_{VCLK}$

29.2.1.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor communication modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

29.2.1.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. Figure 29-6 illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

Method 1: In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

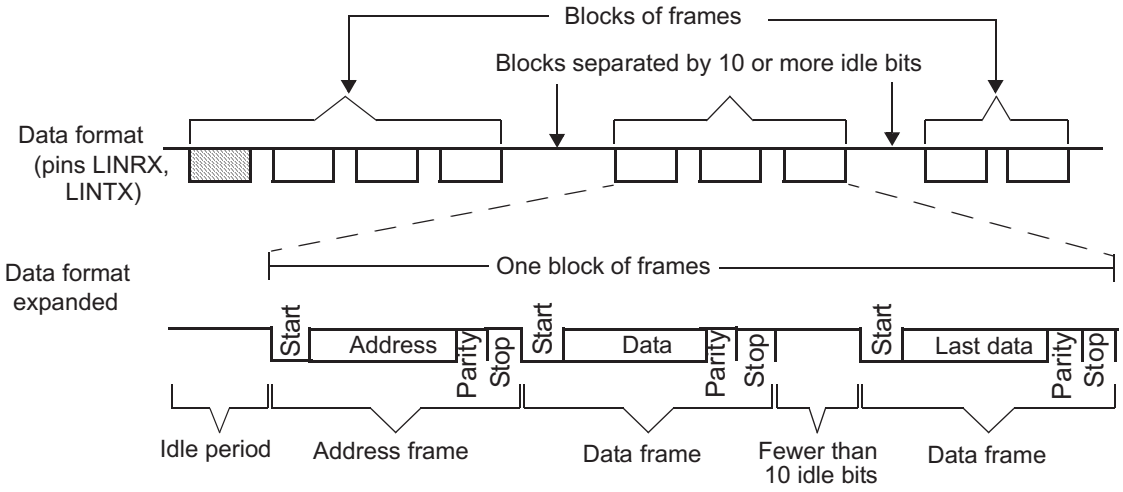
Method 2: Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1: Write a 1 to the TXWAKE bit.

Step 2: Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3: Wait for the SCI to clear the TXWAKE flag.



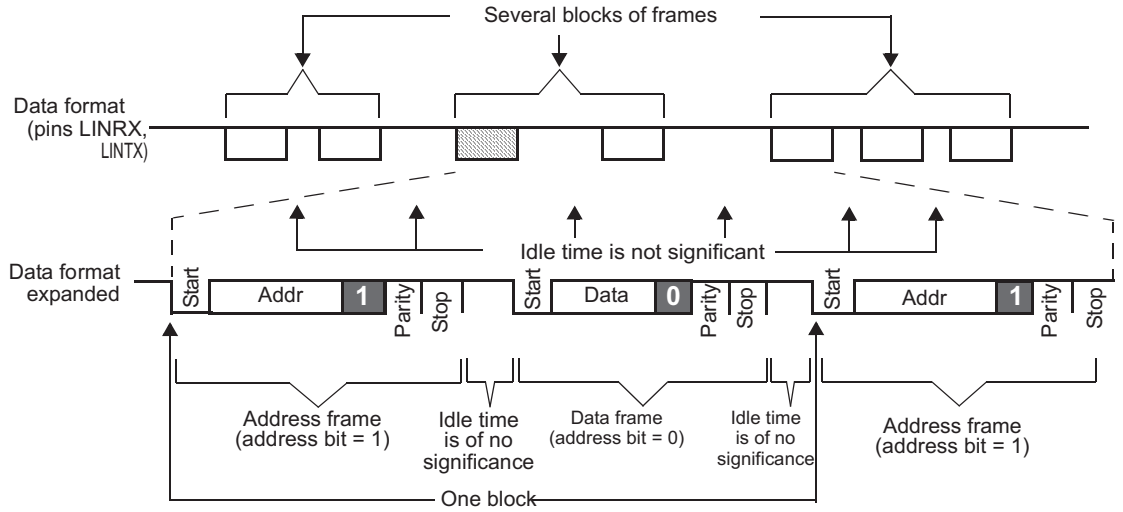
Step 4: Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

Copyright © 2018, Texas Instruments Incorporated

Figure 29-6. Idle-Line Multiprocessor Communication Format



29.2.1.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. Figure 29-7 illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

Figure 29-7. Address-Bit Multiprocessor Communication Format

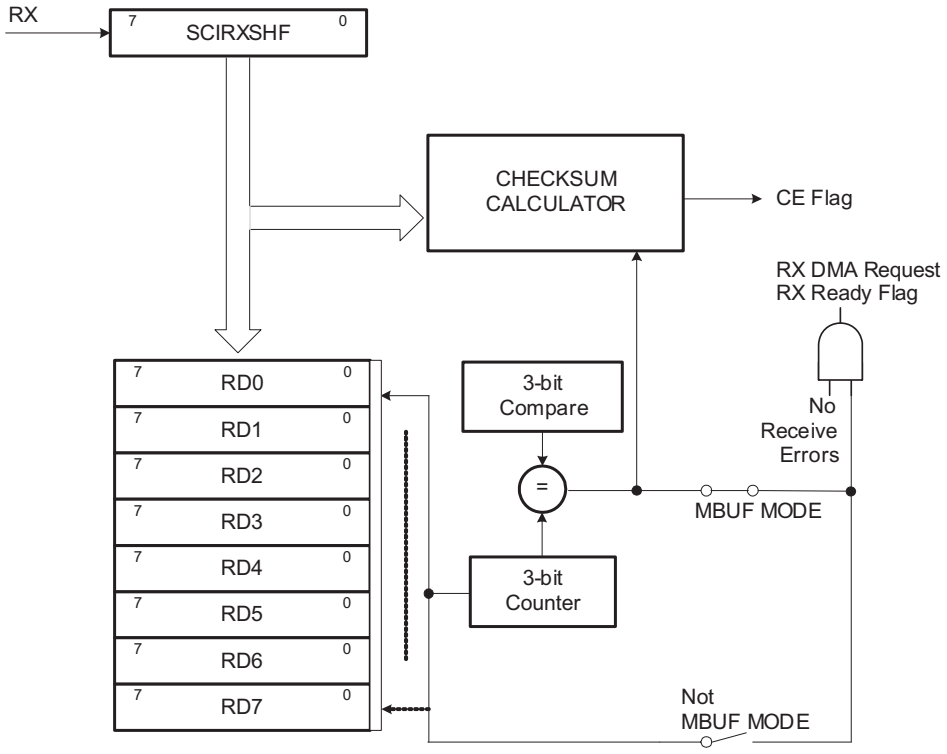
29.2.1.5 SCI Multi Buffered Mode

To reduce CPU load when Receiving or Transmitting data in interrupt mode or DMA mode, the SCI/LIN module has eight separate Receive and transmit buffers. Multi buffered mode is enabled by setting the MBUF MODE bit.



The multi-buffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers and TDy transmit buffers register to SCITXSHF register. The 3-bit compare register contains the number of data bytes expected to be received or transmitted. the LENGTH value in SCIFORMAT register indicates the expected length and is used to load the 3-bit compare register.

A receive interrupt (RX interrupt; see the SCIINTVECT0 and SCIINTVECT1registers), and a receive ready RXRDY flag set in SCIFLR register, as well as a DMA request (RXDMA) could occur after receiving a response if there are no response receive errors for the frame (such as, there is, frame error, and overrun error).

A transmit interrupt (TX interrupt), and a transmit ready flag (TXRDY flag in SCIFLR register), and a DMA request (TXDMA) could occur after transmitting a response.

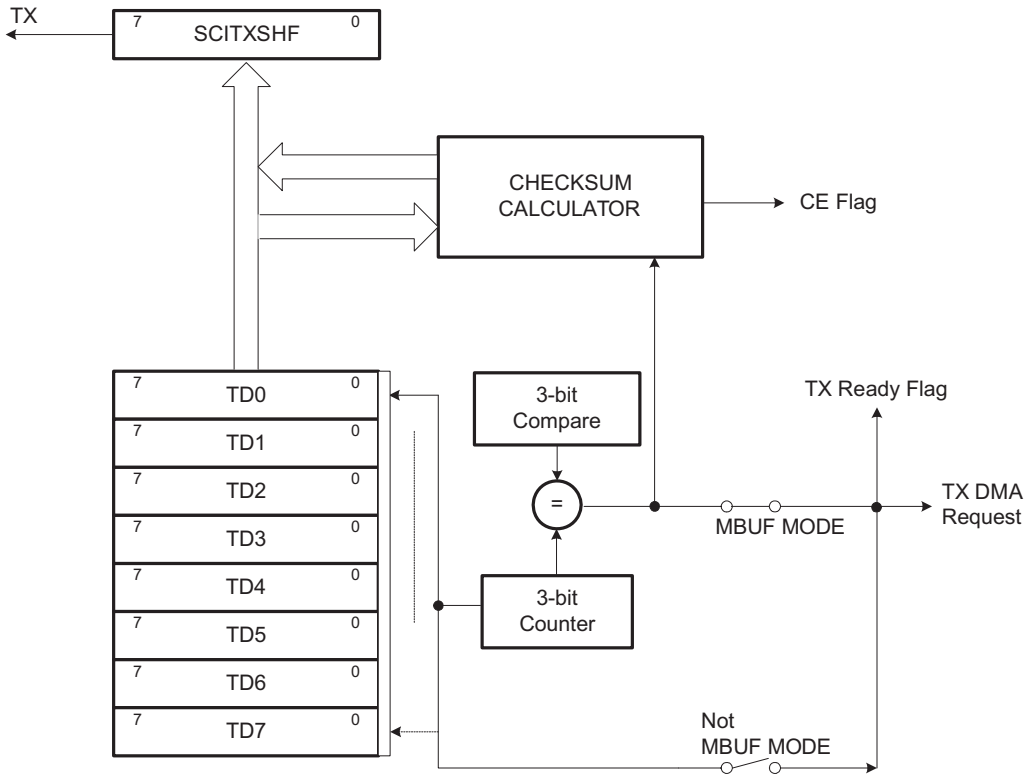


Figure 29-8 and Figure 29-9 shows the receive and transmit multi-buffer functional block diagram.

Figure 29-8. Receive Buffers

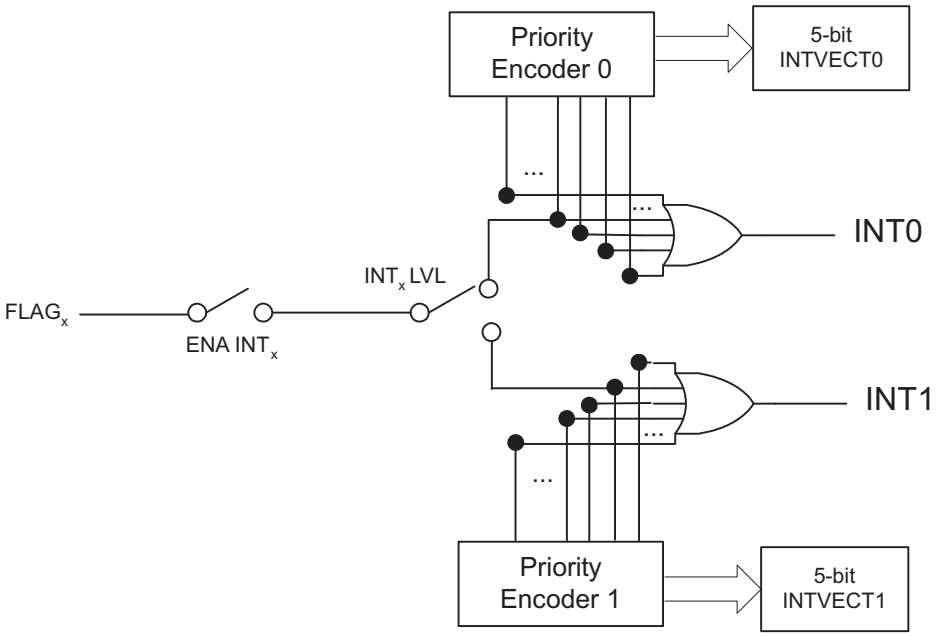
29.2.2 SCI Interrupts

The SCI/LIN module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see Figure 29-10). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISETINT and SCICLRINT registers respectively.

Each interrupt also has a bit that can be set as interrupt level 0(INT0) or as interrupt level 1(INT1). By default, interrupts are in interrupt level 0. SCISETINTLVL sets a given interrupt to level1. SCICLEARINTLVL resets a given interrupt level to the default level 0.



The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

Figure 29-10. General Interrupt Scheme

Copyright © 2018, Texas Instruments Incorporated

Figure 29-11. Interrupt Generation for Given Flags

29.2.2.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled and SET TX DMA bit must be cleared. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT bit unlike transmit DMA request. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD by you before any interrupt gets generated. To transmit further data, you can write data to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

29.2.2.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with both SCI and a DMA controller, the bits SET RX DMA ALL and SET RX DMA must be cleared to select interrupt functionality.

29.2.2.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interrupt is triggered once WAKEUP flag is set.

Copyright © 2018, Texas Instruments Incorporated

29.2.2.4 Error Interrupts

The following error detection are supported with Interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)
- Bit errors (BE)

If all of these errors (PE, FE, BRKDT, OE, BE) are flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register.

There are 16 interrupt sources in the SCI/LIN module, In SCI mode 8 interrupts are supported, as seen in Table 29-4.

Table 29-4. SCI/LIN Interrupts

Offset [1]	Interrupt	Applicable to SCI	Applicable to LIN
0	No interrupt		
1	Wakeup	Yes	Yes
2	Inconsistent-synch-field error	No	Yes
3	Parity error	Yes	Yes
4	ID	No	Yes
5	Physical bus error	No	Yes
6	Frame error	Yes	Yes
7	Break detect	Yes	No
8	Checksum error	No	Yes
9	Overrun error	Yes	Yes
10	Bit error	Yes	Yes
11	Receive	Yes	Yes
12	Transmit	Yes	Yes
13	No-response error	No	Yes
14	Timeout after wakeup signal (150 ms)	No	Yes
15	Timeout after three wakeup signals (1.5 s)	No	Yes
16	Timeout (Bus Idle, 4s)	No	Yes

(1) Offset 1 is the highest priority. Offset 16 is the lowest priority.

Copyright © 2018, Texas Instruments Incorporated

29.2.3 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. The DMA transfers depending on whether multi-buffer mode bit (MBUF MODE) is enabled or not enabled. See Chapter 30 for more information.

29.2.3.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

In Multi-Buffered SCI mode with DMA enabled, the receiver loads the RDy buffers for each received character. RX DMA request is triggered once the last character of the programmed number of characters (LENGTH) are received and copied to the corresponding RDy buffer successfully.

If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

29.2.3.2 Transmit DMA Requests

DMA functionality is enabled/disabled by the CPU with SET TX DMA/CLR TX DMA bits, respectively.

In Multi-Buffered SCI mode once TXRDY bit is set or after a transmission of programmed number of characters (LENGTH) (up to eight data bytes stored in the transmit buffer(s) TDy in the LINTD0 and LINTD1 registers), a DMA request is generated in order to reload the transmit buffer for the next transmission. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis.

Copyright © 2018, Texas Instruments Incorporated

29.2.4 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the LINRX and LINTX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set the LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bitin SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see Section 29.2.4.1 or Section 29.2.4.2).

29.2.4.1 Receiving Data

The SCI receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as an SCI function pin.

SCI module can receive data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multi-Buffer Mode

After a valid idle period is detected, data is automatically received as it arrives on the LINRX pin.

29.2.4.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is cleared to 0. In this mode, SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

Copyright © 2018, Texas Instruments Incorporated

In polling method, software can poll for the RXRDY bit and read the data from the SCIRD register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit is set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set.

29.2.4.1.2 Receiving Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is set to 1. In this mode, SCI sets the RXRDY bit after receiving the programmed number of data in the receive buffer, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that it monitors for the complete frame. Like single-buffer mode, you can use the polling, interrupt, or DMA method to read the data. The SCI clears the RXRDY bit after the new data in SCIRD has been read.

29.2.4.2 Transmitting Data

The SCI transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI module can transmit data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multi-Buffered or Buffered SCI Mode

29.2.4.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is cleared to 0. In this mode, SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit).

NOTE: The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

29.2.4.2.2 Transmitting Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is set to 1. Like single-buffer mode, you can use the polling, interrupt, or DMA method to write the data to be transmitted. The transmitted data has to be written to the SCITD registers. SCI waits for data to be written to the SCITD register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically.

Copyright © 2018, Texas Instruments Incorporated

29.2.5 SCI Low-Power Mode

The SCI/LIN can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the LINRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI/LIN immediately enters low-power mode whenever it is requested and also any activity on the LINRX pin does not cause the SCI to exit low-power mode.

NOTE: Enabling Local Low-Power Mode During Receive and Transmit

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

29.2.5.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Copyright © 2018, Texas Instruments Incorporated

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see Table 29-13) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

29.3 LIN

29.3.1 LIN Communication Formats

The SCI/LIN module can be used in LIN mode or SCI mode. The enhancements for baud generation, DMA controls and additional receive/transmit buffers necessary for LIN mode operation are also part of the enhanced buffered SCI module. LIN mode is selected by enabling LIN MODE bit in SCIGCR1 register.

NOTE: The SCI/LIN is built around the SCI platform and uses a similar sampling scheme: 16 samples for each bit with majority vote on samples 8, 9, and 10.

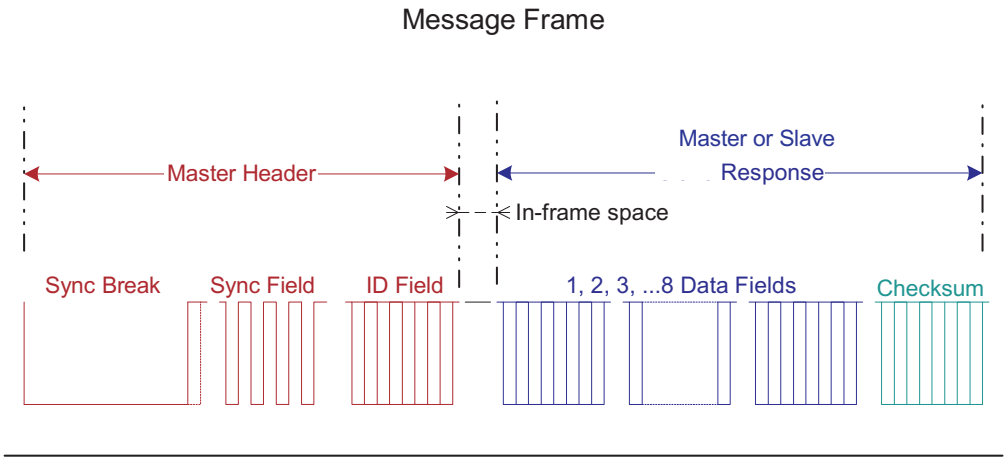
The SCI/LIN control registers are located at the SCI/LIN base address. For a detailed description of each register, see Section 29.7.

29.3.1.1 LIN Standards

For compatibility with LIN2.0 standard the following additional features are implemented over LIN1.3:

i. Support for LIN 2.0 checksum
ii. Enhanced synchronizer FSM support for frame processing
iii. Enhanced handling of extended frames
iv. Enhanced baud rate generator
v. Update wakeup/go to sleep

The LIN module covers the CPU performance-consuming features, defined in the *LIN Specification Package* Revision 1.3 and 2.0 by hardware.



Copyright © 2018, Texas Instruments Incorporated

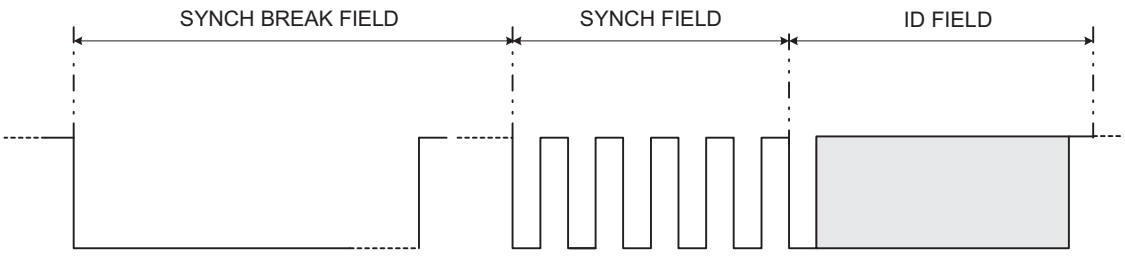
The Master Mode of LIN module is compatible with LIN 2.1 standard.

29.3.1.2 Message Frame

The LIN protocol defines a message frame format, illustrated in Figure 29-12. Each frame includes one master header, one response, one in-frame response space, and inter-byte spaces. In-frame-response and inter-byte spaces may be 0.

Figure 29-12. LIN Protocol Message Frame Format: Master Header and Slave Response

There is no arbitration in the definition of the LIN protocol; therefore, multiple slave nodes responding to a header might be detected as an error.



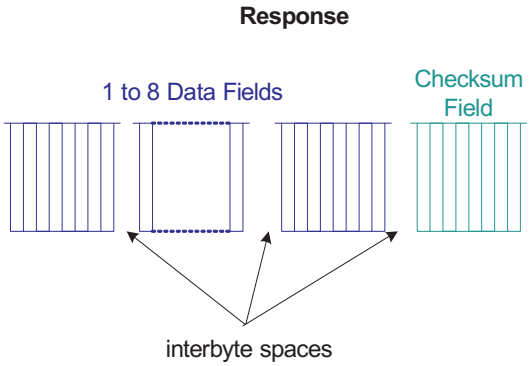
The LIN bus is a single channel wired-AND. The bus has a binary level: either dominant for a value of 0, or recessive for a value of 1.

29.3.1.2.1 Message Header

The header of a message is initiated by a master (see Figure 29-13) and consists of a three field-sequence:

- The synch break field signaling the beginning of a message
- The synch field conveying bit rate information of the LIN bus
- The ID field denoting the content of a message

Figure 29-13. Header 3 Fields: Synch Break, Synch, and ID



Copyright © 2018, Texas Instruments Incorporated

29.3.1.2.2 Response

The format of the response is as illustrated in Figure 29-14. There are two types of fields in a response: data and checksum. The data field consists of exactly one data byte, one start bit, and one stop bit, for a total of 10 bits. The LSB is transmitted first. The checksum field consists of one checksum byte, one start bit and one stop bit. The checksum byte is the inverted modulo-256 sum over all data bytes in the data fields of the response.

Figure 29-14. Response Format of LIN Message Frame

The format of the response is a stream of N data fields and one checksum field. Typically N is from 1 to 8, with the exception of the extended command frames (Section 29.3.1.6). The length N of the response is indicated either with the optional length control bits of the ID Field (this is used in standards earlier than LIN 1.x); see Table 29-5, or by LENGTH value in SCIFORMAT[18:16] register; see Table 29-6. The SCI/LIN module supports response lengths from 1 to 8 bytes in compliance with LIN 2.0.

Table 29-5. Response Length Info Using IDBYTE Field Bits [5:4] for LIN Standards Earlier than 1.3

ID5	ID4	Number of Data bytes
0	0	2
0	1	2
1	0	4
1	1	8

Table 29-6. Response Length with SCIFORMAT[18:16] Programming

SCIFORMAT[18:16]	No. of Bytes

29.3.1.3 Synchronizer

The synchronizer has three major functions in the messaging between master and slave nodes. It generates the master header data stream, it synchronizes to the LIN bus for responding, and it locally detects timeouts. A bit rate is programmed using the prescalers in the BRS register to match the indicated LIN_speed value in the LIN description file.

The LIN synchronizer will perform the following functions: master header signal generation, slave detection and synchronization to message header with optional baud rate adjustment, response transmission timing and timeout control.

The LIN synchronizer is capable of detecting an incoming break and initializing communication at all times.

29.3.1.4 Baud Rate

The transmission baud rate of any node is configured by the CPU at the beginning; this defines the bit time T_{bit}. The bit time is derived from the fields P and M in the baud rate selection register (BRS). There is an additional 3-bit fractional divider value, field U in the BRS register, which further fine-tunes the data field baud rate.

The ranges for the prescaler values in the BRS register are:

P = 0, 1, 2, 3, . . . , 2^{24} - 1

M = 0, 1, 2, . . . , 15

U = 0, 1, 2, 3, 4, 5, 6, 7

The P, M, and U values in the BRS register are user programmable. The P and M dividers could be used for both SCI mode and LIN mode to select a baud rate. The U value is an additional 3-bit value determining that "**a TVCLK**" (with **a** = 0,1) is added to each T_{bit} as explained in Section 29.3.1.4.2. If the ADAPT bit is set and the LIN slave is in adaptive baud rate mode, then all these divider values are automatically obtained during header reception when the synchronization field is measured.

The LIN protocol defines baud rate boundaries as follows:

1kHz ≤ F_{LINCLK} ≤ 20kHz

All transmitted bits are shifted in and out at T_{bit} periods.

29.3.1.4.1 Fractional Divider

The M field of the BRS register modifies the integer prescaler P for fine tuning of the baud rate. The M value adds in increments of 1/16 of the P value.

The bit time, T_{bit} is expressed in terms of the VCLK period T_{VCLK} as follows:

For all P other than 0, and all M,

$$T_{bit} = 16\left(P + 1 + \frac{M}{16}\right)T_{VCLK} \quad (45)$$

For P= 0 : $T_{bit} = 32T_{VCLK}$

Therefore, the LINCLK frequency is given by:

$$F_{LINCLK} = \frac{F_{VCLK}}{16(P + 1 + \frac{M}{16})} \quad \text{For all P other than zero}$$

$$F_{LINCLK} = \frac{F_{VCLK}}{32} \quad \text{For } P = 0 \quad (46)$$

Copyright © 2018, Texas Instruments Incorporated

29.3.1.4.2 Superfractional Divider

The superfractional divider scheme applies to the following modes:

- LIN master mode (synch field + identifier field + response field + checksum field)
- LIN slave mode (response field + checksum field)

29.3.1.4.3 Superfractional Divider In LIN Mode

Building on the 4-bit fractional divider M (BRS[27:24], the superfractional divider uses an additional 3-bit modulating value, illustrated in Table 29-7. The sync field (0x55), the identifier field and the response field can all be seen as 8-bit data bytes flanked by a start bit and a stop bit. The bits with a 1 in the table will have an additional VCLK period added to their T_{bit}.

Table 29-7. Superfractional Bit Modulation for LIN Master Mode and Slave Mode (1)

BRS[30:28]	Start Bit	D[0]	D[1]	D[2]	D[3]	D[4]	D[5]	D[6]	D[7]	Stop Bit
0h	0	0	0	0	0	0	0	0	0	0
1h	1	0	0	0	0	0	0	0	1	0
2h	1	0	0	0	1	0	0	0	1	0
3h	1	0	1	0	1	0	0	0	1	0
4h	1	0	1	0	1	0	1	0	1	0
5h	1	1	1	0	1	0	1	0	1	1
6h	1	1	1	0	1	1	1	0	1	1
7h	1	1	1	1	1	1	1	0	1	1

(1)

1. In LIN master mode bit modulation applies to synch field + identifier field + response field
2. In LIN slave mode bit modulation applies to identifier field + response field

The baud rate will vary over a LIN data field to average according to the BRS[30:28] value by a *d* fraction of the peripheral internal clock: 0<d<1.

The instantaneous bit time is expressed in terms of T_{VCLK} *as follows:*

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK} \quad (47)$$

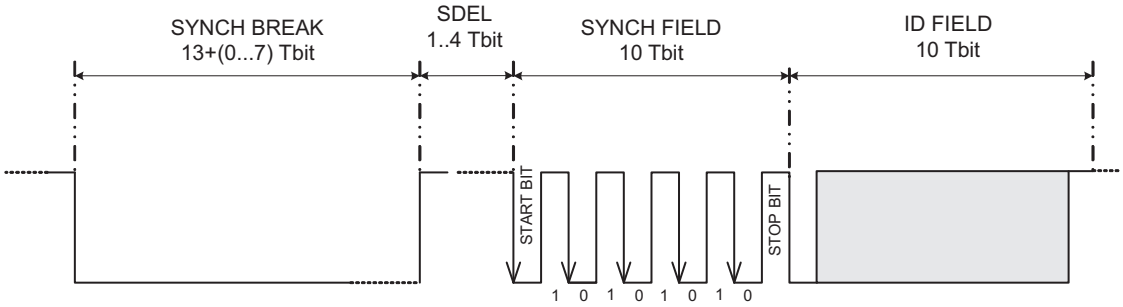
For P = 0 $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of T_{VCLK} as follows*:*

For all P other than 0, and all M and d (0<d<1),

$$T^{a}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK} \quad (48)$$

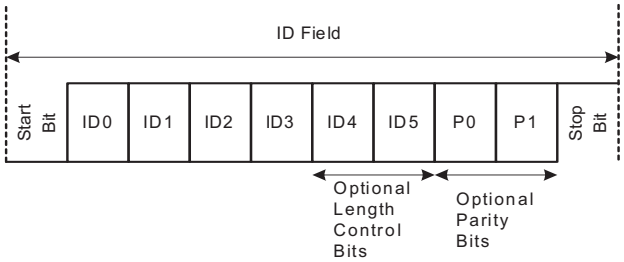
For P = 0 $T_{bit} = 32T_{VCLK}$



With the superfractional divider, a LIN baud rate of 20 kbps is achievable with an internal clock VCLK of 726 kHz. Furthermore, a rate of 400 kbps is achievable with an VCLK of 14.6 MHz.

Copyright © 2018, Texas Instruments Incorporated

29.3.1.5 Header Generation



Automatic generation of the LIN protocol header data stream is supported without CPU interaction. The CPU pr the DMA will trigger a message header generation and the LIN state machine will handle the generation itself. A master node initiates header generation on CPU or DMA writes to the IDBYTE in the LINID register. The header is always sent by the master to initiate a LIN communication and consists of three fields: break field, synchronization field, and identification field, as seen in Figure 29-15.

Figure 29-15. Message Header in Terms of T_{bit}

- The break field consists of two components:
  - The synchronization break (SYNCH BREAK) consists of a minimum of 13 (dominant) low bits to a maximum of 20 dominant bits. The synch break length may be extended from the minimum with the 3-bit SBREAK value in the LINCOMP register.
  - The synchronization break delimiter (SDEL) consists of a minimum of 1 (recessive) high bit to a maximum of 4 recessive bits. The delimiter marks the end of the synchronization break field. The synch break delimiter length depends on the 2-bit SDEL value in the LINCOMP register.
- The synchronization field (SYNCH FIELD) consists of one start bit, byte 0x55, and a stop bit. It is used to convey T_{bit} information and resynchronize LIN bus nodes.
- The identifier field's ID byte may use six bits as an identifier, with optional length control (see *Note:Optional Control Length Bits*), and two optional bits as parity of the identifier. The identifier parity is used and checked if the PARITY ENA bit is set. If length control bits are not used, then there can be a total of 64 identifiers plus parity. If neither length control or parity are used there can be up to 256 identifiers. See Figure 29-16 for an illustration of the ID field.

Figure 29-16. ID Field

NOTE: Optional Control Length Bits

The control length bits only apply to LIN standards prior to LIN 1.3. IDBYTE field conveys response length information if compliant to standards earlier than LIN1.3. The SCIFORMAT register stores the length of the response for later versions of the LIN protocol.

Copyright © 2018, Texas Instruments Incorporated

NOTE: If the BLIN module, configured as Slave in multi-buffer mode, is in the process of transmitting data while a new header comes in, the module might end up in responding with the data from the previous interrupted response (not the data corresponding to the new ID). To avoid this scenario the following procedure could be used:

1. Check for the Bit Error (BE) during the response transmission. If the BE flag is set, this indicates that a collision has happened on the LIN bus (here because of the new Synch Break).
2. In the Bit Error ISR, configure the TD0 and TD1 registers with the next set of data to be transmitted on a TX Match for the incoming ID. Before writing to TD0/TD1 make sure that there was not already an update because of a Bit Error; otherwise TD0/TD1 might be written twice for one ID.
3. Once the complete ID is received, based on the match, the newly configured data will be transmitted by the node.

29.3.1.5.1 Event Triggered Frame Handling Proposal

The LIN 2.0 protocol uses event-triggered frames that may occasionally cause collisions. Event-triggered frames have to be handled in software.

If no slave answers to an event triggered frame header, the master node will set the NRE flag, and a NRE interrupt will occur if enabled. If a collision occurs, a frame error and checksum error may arise before the NRE error. Those errors are flagged and the appropriate interrupts will occur, if enabled.

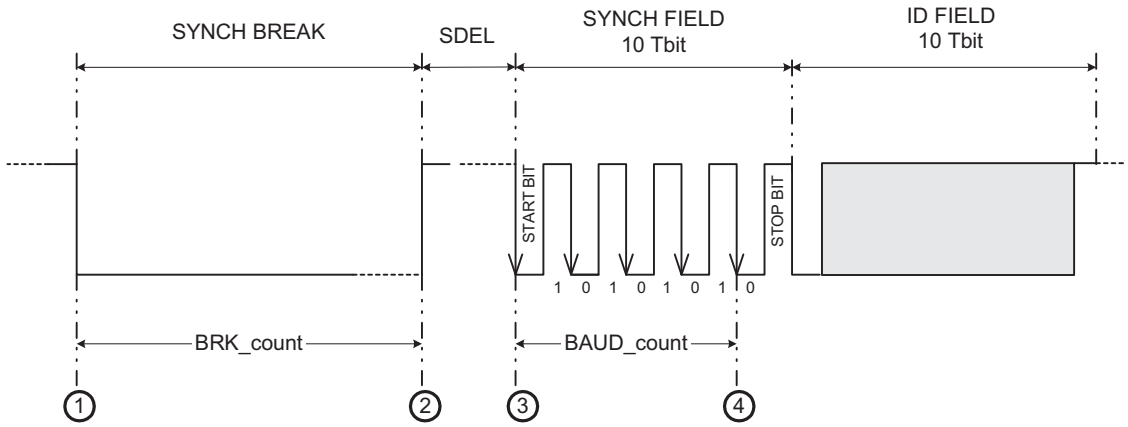
Frame errors and checksum errors depend on the behavior and synchronization of the responding slaves. If the slaves are totally synchronized and stop transmission once the collision occurred, it is possible that only the NRE error is flagged despite the occurrence of a collision. To detect if there has been a reception of one byte before the NRE error is flagged, the BUS BUSY flag can be used as an indicator.

The bus busy flag is set on the reception of the first bit of the header and remains set until the header reception is complete, and again is set on the reception of the first bit of the response. In the case of a collision the flag is cleared in the same cycle as the NRE flag is set.

Software could implement the following sequence:

- Once the reception of the header is done (poll for RXID flag), wait for the bus busy flag to get set or NRE flag to get set.
- If bus busy flag is not set before NRE flag, then it is a true no response case (no data has been transmitted onto the bus).
- If bus busy flag gets set, then wait for NRE flag to get set or for successful reception. If NRE flag is set, then in this case a collision has occurred on the bus.

Even in the case of a collision, the received (corrupted) data is accessible in the RX buffers; registers LINRD0 and LINRD1.



Copyright © 2018, Texas Instruments Incorporated

29.3.1.5.2 Header Reception and Adaptive Baud Rate

A slave node baud rate can optionally be adjusted to the detected bit rate as an option to the LIN module. The adaptive baud rate option is enabled by setting the ADAPT bit. During header reception, a slave measures the baud rate during detection of the synch field. If ADAPT bit is set, then the measured baud rate is compared to the slave node's programmed baud rate and adjusted to the LIN bus baud rate if necessary.

The LIN synchronizer determines two measurements: BRK_count and BAUD_count (Figure 29-17). These values are always calculated during the Header reception for synch field validation (Figure 29-18).

Figure 29-17. Measurements for Synchronization

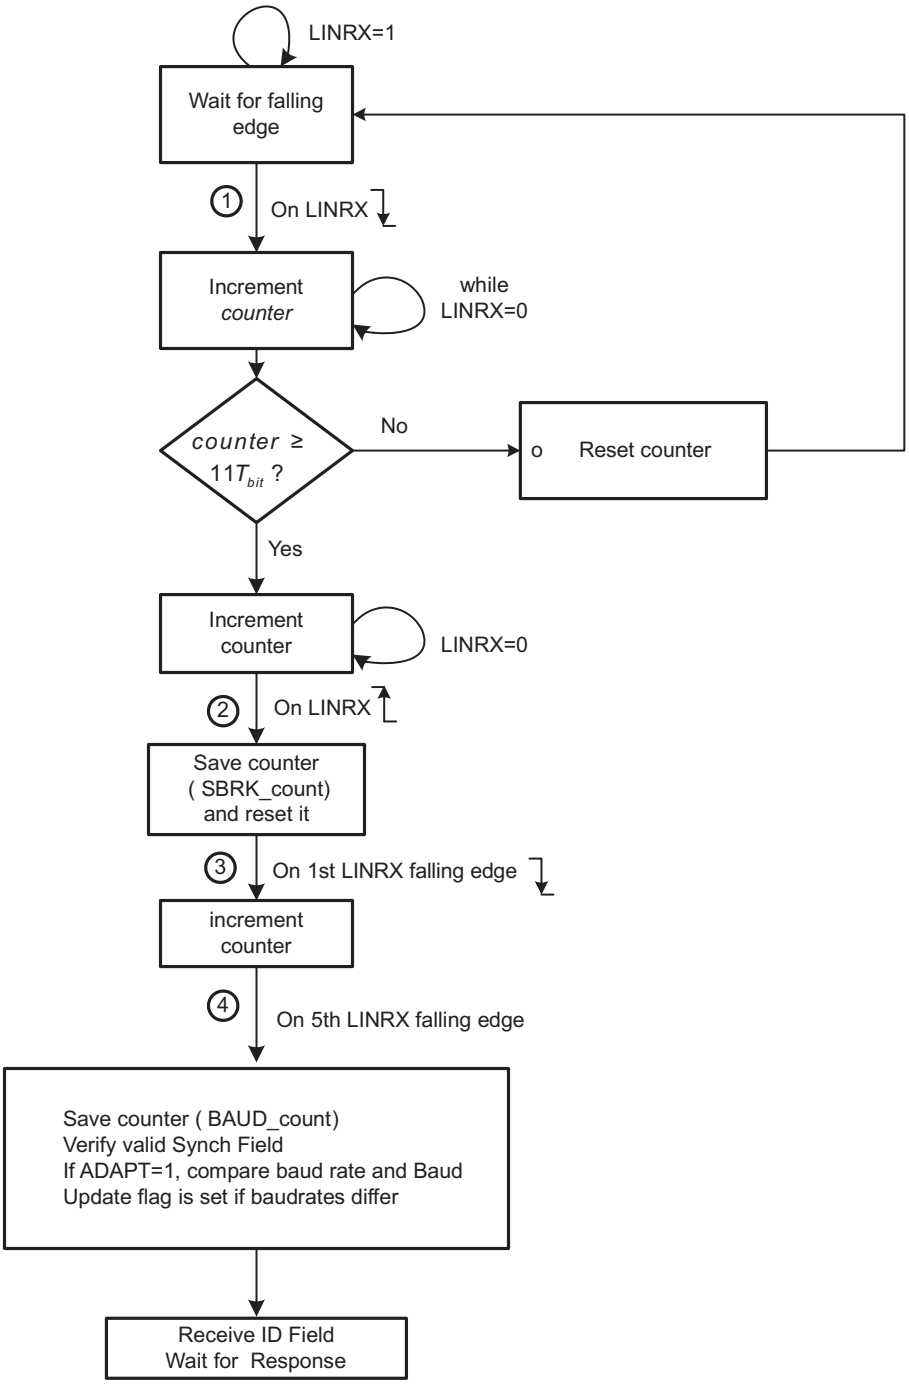
By measuring the values BRK_count and BAUD_count, a valid synch break sequence can be detected as described in Figure 29-18. The four numbered events in Figure 29-17 signal the start/stop of the synchronizer counter. The synchronizer counter uses VCLK as the time base.

The synchronizer counter is used to measure the synch break relative to the detecting node T_{bit}. For a slave node receiving the synch break, a threshold of 11 T_{bit} is used as required by the LIN protocol. For detection of the dominant data stream of the synch break, the synchronizer counter is started on a falling edge and stopped on a rising edge of the LINRX. On detection of the synch break delimiter, the synchronizer counter value is saved and then reset.

On detection of five consecutive falling edges, the BAUD_count is measured. Bit timing calculation and consistency to required accuracy is implemented following the recommendations of LIN revision 2.0. A slave node can calculate a single T_{bit} time by division of BAUD_count by 8. In addition, for consistency between the detected edges the following is evaluated:

BAUD_count + BAUD_count » 2 + BAUD_count » 3 ≤ BRK_count

The BAUD_count value is shifted 3 times to the right and rounded using the first insignificant bit to obtain a T_{bit} unit. If the ADAPT bit is set, then the detected baud rate is compared to the programmed baud rate.



During the header reception processing as illustrated in Figure 29-18, if the measured BRK_count value is less than 11 T_{bit}, the synch break is not valid according to the protocol for a fixed rate. If the ADAPT bit is set, then the MBRS register is used for measuring BRK_count and BAUD_count values and automatically adjusts to any allowed LIN bus rate (refer to *LIN Specification Package 2.0*).

NOTE: In adaptive mode the MBRS divider should be set to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise, a 0x00 data byte could mistakenly be detected as a synch break.

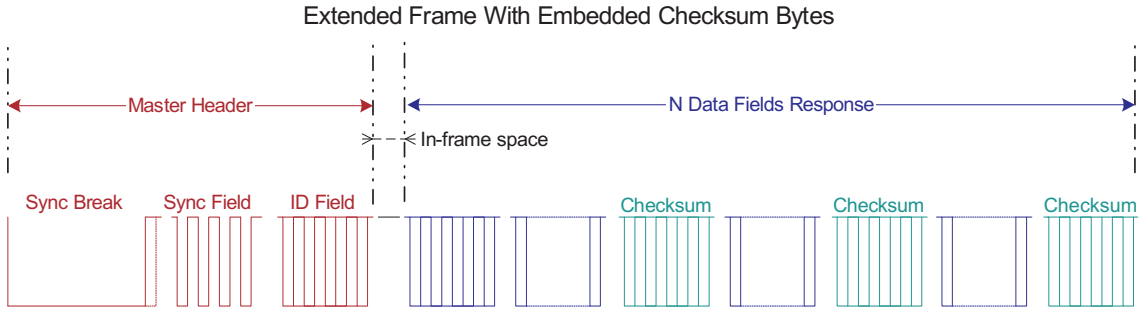
The break-threshold relative to the slave node is 11 T_{bit}. The break is 13 T_{bit} as specified in LIN version 1.3.

Copyright © 2018, Texas Instruments Incorporated

Figure 29-18. Synchronization Validation Process and Baud Rate Adjustment

If the synch field is not detected within the given tolerances, the inconsistent-synch-field-error (ISFE) flag will be set. An ISFE interrupt will be generated, if enabled by its respective bit in the SCISETINT register. The ID byte should be received after the synch field validation was successful. Any time a valid break (larger than 11 T_{bit}) is detected, the receiver's state machine should reset to reception of this new frame. This reset condition is only valid during response state, not if an additional synch break occurs during header reception.

Copyright © 2018, Texas Instruments Incorporated



NOTE: When an inconsistent synch field (ISFE) error occurs, suggested action for the application is to Reset the SWnRST bit and set the SWnRST bit to make sure that the internal state machines are back to their normal states

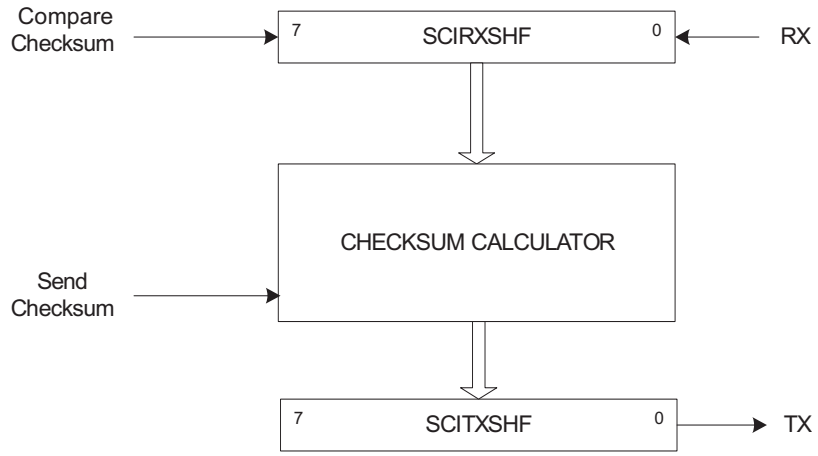
29.3.1.6 Extended Frames Handling

The LIN protocol 2.0 and prior includes two extended frames with identifiers 62 (user-defined) and 63 (reserved extended). The response data length of the user-defined frame (ID 62, or 0x3E) is unlimited. The length for this identifier will be set at network configuration time to be shared with the LIN bus nodes.

Extended frame communication is triggered on reception of a header with identifier 0x3E; see Figure 29-19. Once the extended frame communication is triggered, unlike normal frames, this communication needs to be stopped before issuing another header. To stop the extended frame communication the STOP EXT FRAME bit must be set.

Figure 29-19. Optional Embedded Checksum in Response for Extended Frames

An ID interrupt will be generated (if enabled and there is a match) on reception of ID 62 (0x3E). This interrupt allows the CPU using a software counter to keep track of the bytes that are being sent out and decides when to calculate and insert a checksum byte (recommended at periodic rates). To handle this procedure, SC bit is used. A write to the send checksum bit SC will initiate an automatic send of the checksum byte. The last data field should always be a checksum in compliance with the LIN protocol.



The periodicity of the checksum insertion, defined at network configuration time, is used by the receiving node to evaluate the checksum of the ongoing message, and has the benefit of enhanced reliability.

For the sending node, the checksum is automatically embedded each time the send checksum bit SC is set. For the receiving node, the checksum is compared each time the compare checksum bit CC is set; see Figure 29-20.

NOTE: The LIN 2.0 enhanced checksum does not apply to the reserved identifiers. The reserved identifiers always use the classic checksum.

Copyright © 2018, Texas Instruments Incorporated

Figure 29-20. Checksum Compare and Send for Extended Frames

29.3.1.7 Timeout Control

Any LIN node listening to the bus and expecting a response initiated from a master node could flag a no-response error timeout event. The LIN protocol defines four types of timeout events, which are all handled by the hardware of the LIN module. The four LIN protocol events are:

- No-response timeout error
- Bus idle detection
- Timeout after wakeup signal
- Timeout after three wakeup signals

29.3.1.7.1 No-Response Error (NRE)

The no-response error will occur when any node expecting a response waits for T_{FRAME_MAX} time and the message frame is not fully completed within the maximum length allowed, T_{FRAME_MAX}. After this time a no-response error (NRE) is flagged in the NRE bit of the SCIFLR register. An interrupt is triggered if enabled.

As specified in the LIN 1.3 standard, the minimum time to transmit a frame is:

$T_{FRAME\_MIN} = T_{HEADER\_MIN} + T_{DATA\_FIELD} + T_{CHECKSUM\_FIELD}$

$= 44 + 10N$

where N = number of data fields.

And the maximum time frame is given by:

$T_{FRAME\_MAX} = T_{FRAME\_MIN} * 1.4$

$= (44 + 10N) * 1.4$

The timeout value T_{FRAME_MAX} is derived from the *N* number of data fields value. The *N* value is either embedded in the header's ID field for messages or is part of the description file. In the latter case, the 3-bit CHAR value in SCIFORMAT register, will indicate the value for *N*.

NOTE: The length coding of the ID field does not apply to two extended frame identifiers, ID fields of 0x3E (62) and 0x3F (63). In these cases, the ID field can be followed by an arbitrary number of data byte fields. Also, the LIN 2.0 protocol specification mentions that ID field 0x3F (63) cannot be used. For these two cases, the NRE will not be handled by the LIN controller hardware.

Copyright © 2018, Texas Instruments Incorporated

Table 29-8. Timeout Values in T_{bit} Units

N	T_{DATA_FIELD}	T_{FRAME_MIN}	T_{FRAME_MAX}
1	10	54	76
2	20	64	90
3	30	74	104
4	40	84	118
5	50	94	132
6	60	104	146
7	70	114	160
8	80	124	174

29.3.1.7.2 Bus Idle Detection

The second type of timeout can occur when a node detects an inactive LIN bus: no transitions between recessive and dominant values are detected on the bus. This happens after a minimum of 4 s (this is 80,000 F_{LINCLK} cycles with the fastest bus rate of 20 kbps). If a node detects no activity in the bus as the TIMEOUT bit is set, then it can be assumed that the LIN bus is in sleep mode. Application software can use the Timeout flag to determine when the LIN bus is inactive and put the LIN into sleep mode by writing the POWERDOWN bit.

NOTE: After the timeout was flagged, a SW nRESET should be asserted before entering Low-Power Mode. This is required to reset the receiver in case that an incomplete frame was on the bus before the idle period.

29.3.1.7.3 Timeout after Wakeup Signal and Timeout after Three Wakeup Signals

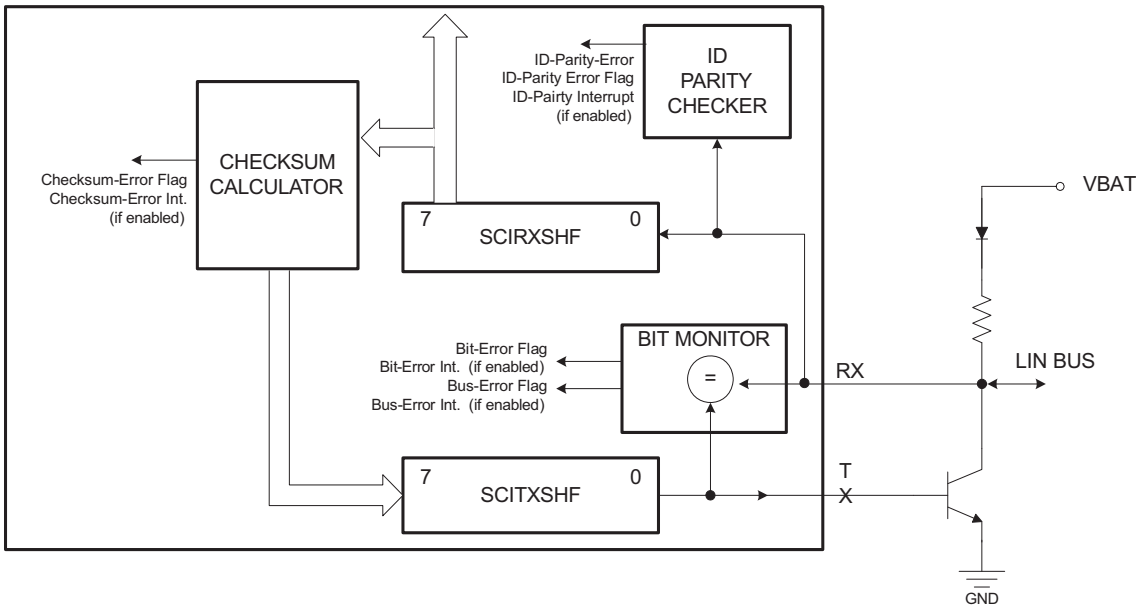
The third and fourth types of timeout are related to the wakeup signal. A node initiating a wakeup should expect a header from the master within a defined amount of time: timeout after wakeup signal. See Section 29.4.3 for more details.

29.3.1.8 TXRX Error Detector (TED)

The following sources of error are detected by the TXRX error detector logic (TED). The TED logic consists of a bit monitor, an ID parity checker, and a checksum error. The following errors are detected:

- Bit errors (BE)
- Physical bus errors (PBE)
- Identifier parity errors (PE)
- Checksum errors (CE)

All of these errors (BE, PBE, PE, CE) are flagged. An interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame.



Copyright © 2018, Texas Instruments Incorporated

29.3.1.8.1 Bit Errors

A bit error (BE) is detected at the bit time when the bit value that is monitored is different from the bit value that is sent. A bit error is indicated by the BE flag in SCIFLR. After signaling a BE, the transmission is aborted no later than the next byte. The bit monitor ensures that the transmitted bit in LINTX is the correct value on the LIN bus by reading back on the LINRX pin as shown in Figure 29-21.

NOTE: If BE Occurs due to New Header reception during a Slave Response, NRE/TIMEOUT flag will not be set for the new Frame.

Figure 29-21. TXRX Error Detector

29.3.1.8.2 Physical Bus Errors

A Physical Bus Error (PBE) has to be detected by a master if no valid message can be generated on the bus (Bus shorted to GND or VBAT). The bit monitor detects a PBE during the header transmission, if no Synch Break can be generated (for example, because of a bus shortage to VBAT) or if no Synch break Delimiter can be generated (for example, because of a bus shortage to GND). Once the Synch Break Delimiter was validated, all other deviations between the monitored and the sent bit value are flagged as Bit Errors (BE) for this frame.

29.3.1.8.3 ID Parity Errors

If parity is enabled, an ID parity error (PE) is detected if any of the two parity bits of the sent ID byte are not equal to the calculated parity on the receiver node. The two parity bits are generated using the following mixed parity algorithm.

$$P0 = ID0 \oplus ID1 \oplus ID2 \oplus ID4 \ (even\ Parity)$$
$$P1 = ID1 \oplus ID3 \oplus ID4 \oplus ID5 \ (odd\ Parity) \quad (49)$$

If an ID-parity error is detected, the ID-parity error is flagged, and the received ID is not valid. See Section 29.3.1.9 for details.

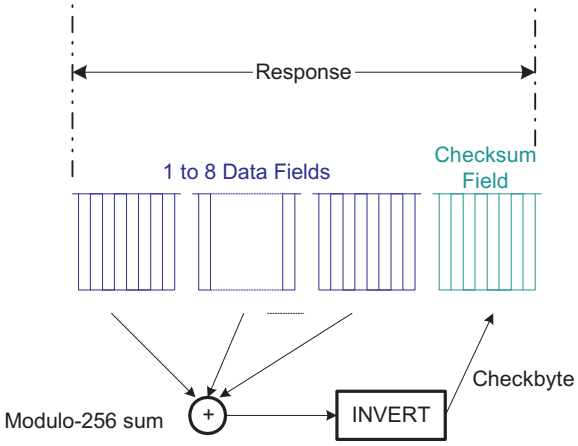
Copyright © 2018, Texas Instruments Incorporated

29.3.1.8.4 Checksum Errors

A checksum error (CE) is detected and flagged at the receiving end if the calculated modulo-256 sum over all received data bytes (including the ID byte if it is the enhanced checksum type) plus the checksum byte does not result in 0xFF. The modulo-256 sum is calculated over each byte by adding with carry, where the carry bit of each addition is added to the LSB of its resulting sum.

For the transmitting node, the checksum byte sent at the end of a message is the inverted sum of all the data bytes (see Figure 29-22) for classic checksum implementation. The checksum byte is the inverted sum of the identifier byte and all the data bytes (see Figure 29-23) for the LIN 2.0 compliant enhanced checksum implementation. The classic checksum implementation should always be used for reserved identifiers 60 to 63; therefore, the CTYPE bit will be overridden in this case. For signal-carrying-frame identifiers (0 to 59) the type of checksum used depends on the CTYPE bit.

Figure 29-22. Classic Checksum Generation at Transmitting Node



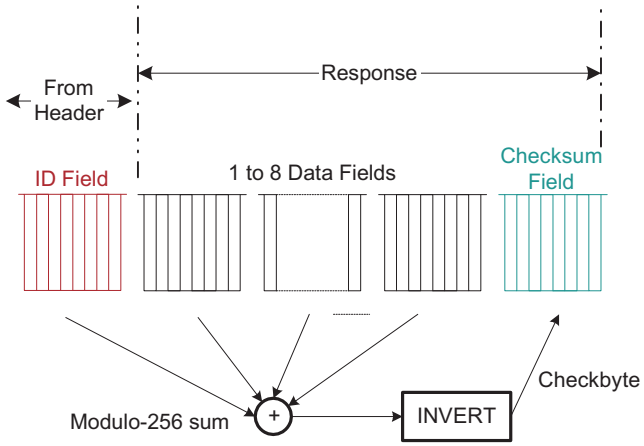


Figure 29-23. LIN 2.0-Compliant Checksum Generation at Transmitting Node

Copyright © 2018, Texas Instruments Incorporated

29.3.1.9 Message Filtering and Validation

Message filtering uses the entire identifier to determine which nodes will participate in a response, either receiving or transmitting a response. Therefore, two acceptance masks are used as shown in Figure 29-24. During header reception, all nodes filter the ID-Field (ID-Field is the part of the header explained in Figure 29-16) to determine whether they transmit a response or receive a response for the current message. There are two masks for message ID filtering: one to accept a response reception, the other to initiate a response transmission. See Figure 29-24. All nodes compare the received ID to the identifier stored in the ID-SlaveTask BYTE of the LINID register and use the RX ID MASK and the TX ID MASK fields in the LINMASK register to filter the bits of the identifier that should not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there will be an ID RX flag and an interrupt will be triggered if enabled. If there is a TX match with no parity error and the TXENA bit is set, there will be an ID TX flag and an interrupt will be triggered if enabled in the SCISETINT register.

The masked bits become don't cares for the comparison. To build a mask for a set of identifiers, an XOR function could be used.

For example, to build a mask to accept IDs 0x26 and 0x25 using LINID[7:0] = 0x20; that is, compare 5 most significant bits (MSBs) and filter 3 least significant bits (LSBs), the acceptance mask could be:

$$(0x26 + 0x25) \oplus 0x20 = 0x07 \tag{50}$$

A mask of all zeros will compare all bits of the received identifier in the shift register with the ID-BYTE in LINID[7:0]. If HGEN CTRL is set to 1, a mask of 0xFF will always cause a match. A mask of all 1s will filter all bits of the received identifier, and thus there will be an ID match regardless of the content of the ID-SlaveTask BYTE field in the LINID register.

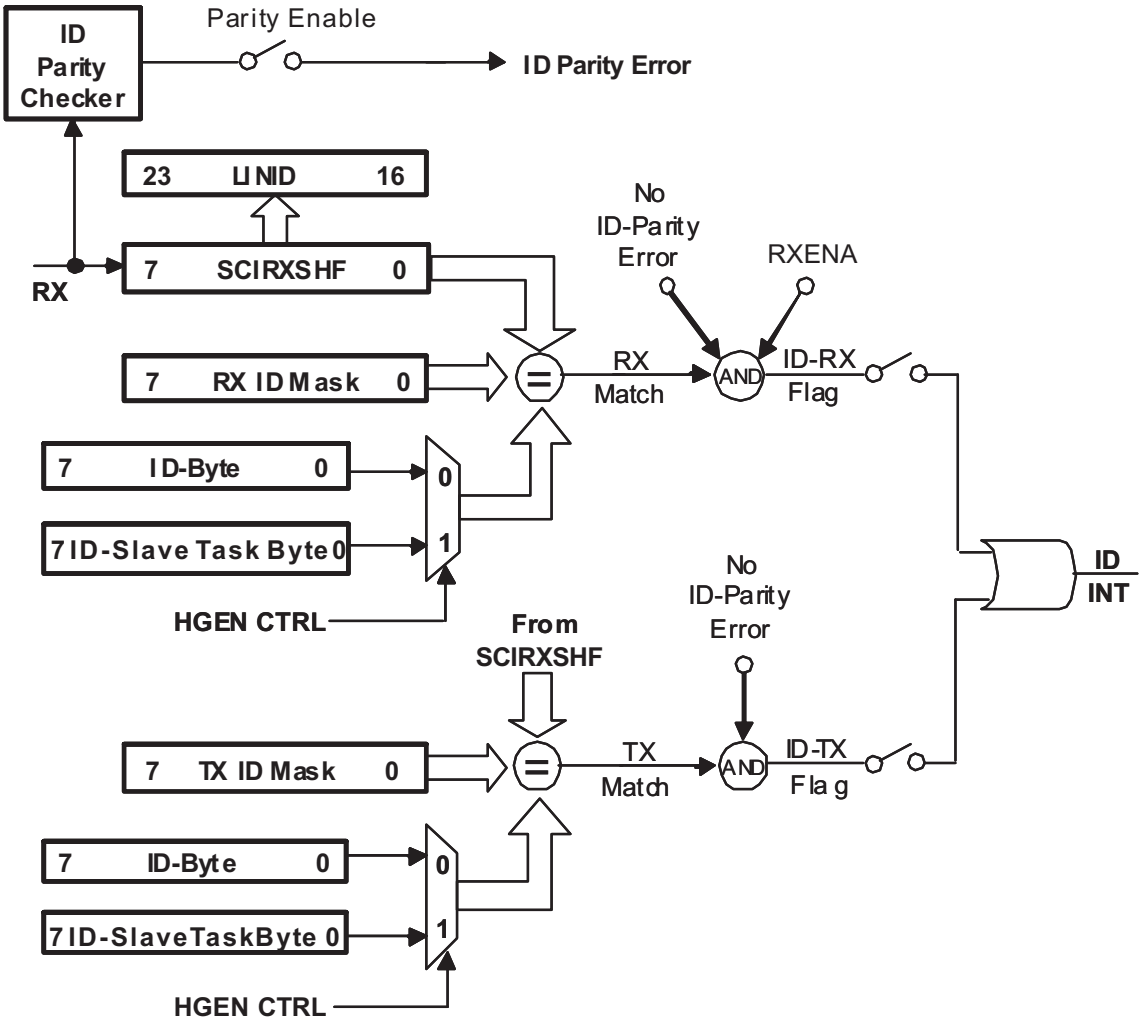
NOTE: When the HGEN CTRL bit = 0, the LIN nodes compare the received ID to the ID-BYTE field in the LINID register, and use the RX ID MASK and the TX ID MASK in the LINMASK register to filter the bits of the identifier that should not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there will be an ID RX flag and an interrupt will be triggered if enabled. A mask of all 0s will compare all bits of the received identifier in the shift register with the ID-BYTE field in LINID[7:0]. A mask of all 1s will filter all bits of the received identifier and there will be no match.

During header reception, the received identifier is copied to the Received ID field LINID[23:16]. If there is no parity error and there is either a TX match or an RX match, then the corresponding TX or RX ID flag is set. If the ID interrupt is enabled, then an ID interrupt is generated.

After the ID interrupt is generated, the CPU may read the Received ID field LINID[23:16] and determine what response to load into the transmit buffers.

NOTE: When byte 0 is written to TD0 (LINTD0[31:24]), the response transmission is automatically generated.



In multi-buffer mode, the TXRDY flag will be set when all the response data bytes and checksum byte are copied to the shift register SCITXSHF. In non-multi-buffer mode, the TXRDY flag is set each time a byte is copied to the SCITXSHF register, and also for the last byte of the frame after the checksum byte is copied to the SCITXSHF register.

In multi-buffer mode, the TXEMPTY flag is set when both the transmit buffer(s) TDy and the SCITXSHF shift register are emptied and the checksum has been sent. In nonmulti-buffer mode, TXEMPTY is set each time TD0 and SCITXSHF are emptied, except for the last byte of the frame where the checksum byte must also be transmitted.

If parity is enabled, all slave receiving nodes will validate the identifier using all eight bits of the received ID byte. The SCI/LIN will flag a corrupted identifier if an ID-parity error is detected.

29.3.1.10 Receive Buffers

To reduce CPU load when receiving a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight receive buffers. These buffers can store an entire LIN response in the RDy receive buffers. Figure 29-8 illustrates the receive buffers.

The checksum byte following the data bytes is validated by the internal checksum calculator. The checksum error (CE) flag indicates a checksum error and a CE interrupt will be generated if enabled in the SCISETINT register.

The multi-buffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers if multi-buffer mode is enabled, or to RD0 if multi-buffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be received. In cases where the ID BYTE field does not convey message length (see *Note:Optional Control Length Bits* in Section 29.3.1.5), the LENGTH value, indicates the expected length and is used to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMM MODE bit.

A receive interrupt, and a receive ready RXRDY flag set as well as a DMA request (RXDMA) could occur after receiving a response if there are no response receive errors for the frame (such as, there is no checksum error, frame error, and overrun error). The checksum byte will be compared before acknowledging a reception. A DMA request can be generated for each received byte or for the entire response depending on whether the multi-buffer mode is enabled or not (MBUF MODE bit).

NOTE: In multi-buffer mode following are the scenarios associated with clearing the "RXRDY" flag bit:

1. The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.
2. For LENGTH less than or equal to 4, Read to RD0 register will clear the “RXRDY” flag.
3. For LENGTH greater than 4, Read to RD1 register will clear the “RXRDY” flag.

29.3.1.11 Transmit Buffers

To reduce the CPU load when transmitting a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight transmit buffers, TD0–TD7 in LINTD0 and LINTD1. With these transmit buffers, an entire LIN response field can be preloaded in the TXy transmit buffers. Optionally, a DMA transfer could be done on a byte-per-byte basis when multi-buffer mode is not enabled (MBUF MODE bit). Figure 29-9 illustrates the transmit buffers.

The multi-buffer 3-bit counter counts the data bytes transferred from the TDy transmit buffers register if multi-buffer mode is enabled, or from TD0 to SCITXSHF if multi-buffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be transmitted. If the ID field is not used to convey message length (see *Note:Optional Control Length Bits* in Section 29.3.1.5), the LENGTH value indicates the expected length and is used instead to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMM MODE bit.

A transmit interrupt (TX interrupt), and a transmit ready flag (TXRDY flag), and a DMA request (TXDMA) could occur after transmitting a response. A DMA request can be generated for each transmitted byte or for the entire response depending on whether multi-buffer mode is enabled or not (MBUF MODE bit).

The checksum byte will be automatically generated by the checksum calculator and sent after the data-fields transmission is finished. The multi-buffer 3-bit counter counts the data bytes transferred from the TDy buffers into the SCITXSHF register.

NOTE: The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLRINT register or by disabling the transmitter via the TXENA bit.

29.3.2 LIN Interrupts

LIN and SCI mode have a common Interrupt block as explained in Section 29.2.2. There are 16 interrupt sources in the SCI/LIN module, with 8 of them being LIN mode only, as seen in Table 29-4.

A LIN message frame indicating the timing and sequence of the LIN interrupts that could occur is shown in Figure 29-25.

Figure 29-25. LIN Message Frame Showing LIN Interrupt Timing and Sequence

29.3.3 LIN DMA Interface

LIN DMA Interface uses the SCI DMA interface logic. DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. There are two modes for DMA transfers depending on whether multi-buffer mode is enabled or not via the multi-buffer enable control bit (MBUF MODE).

29.3.3.1 LIN Receive DMA Requests

In LIN mode, when the multi-buffer option is enabled, if a received response (up to eight data bytes) is transferred to the receive buffers (RDy), then a DMA request is generated. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all the expected response data fields are received. This DMA functionality is enabled and disabled using the SET RX DMA and CLR RX DMA bits, respectively.

29.3.3.2 LIN Transmit DMA Requests

In LIN mode with the multi-buffer option enabled, after a transmission (up to eight data bytes stored in the transmit buffer(s) TDy in the LINTD0 and LINTD1 registers), a DMA request is generated in order to reload the transmit buffer for the next transmission. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all bytes are transferred. This DMA functionality is enabled and disabled using the SET TX DMA and CLR TX DMA bits, respectively.

29.3.4 LIN Configurations

The following list details the configuration steps that software should perform prior to the transmission or reception of data in LIN mode. As long as the SWnRST bit in the SCIGCR1 register is cleared to 0 the entire time that the LIN is being configured, the order in which the registers are programmed is not important.

- Enable LIN by setting the RESET bit in SCIGCR0 to 1.
- Clear the SWnRST bit to 0 before LIN is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the LINRX and LINTX pins for LIN functionality.
- Set the LIN MODE bit in SCIGCR1 to 1 to enable LIN mode.
- Select Master or Slave mode by programming the CLOCK bit in SCIGCR1.
- Set the MBUF MODE bit in SCIGCR1 to 1 to select multi-buffer mode.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the maximum baud rate to be used for communication by programming the BMRS register.
- Set the CONT bit in SCIGCR1 to 1 to make LIN not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set the LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bit in SCIGCR1 to 1, if data is to be transmitted.
- Select the RX ID MASK and the TX ID MASK fields in the LINMASK register.
- Set the SWnRST bit to 1 after LIN is configured.
- Perform receiving or transmitting data (see Section 29.3.4.1 or Section 29.3.4.2).

29.3.4.1 Receiving Data

The LIN receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as a LIN function pin.

The ID RX FLAG is set after a valid LIN ID is received with RX Match. An ID interrupt is generated, if enabled.

29.3.4.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit is cleared to 0. In this mode, LIN sets the RXRDY bit when it transfers newly received data from SCIRXSHF to RD0. The SCI clears the RXRDY bit after the new data in RD0 has been read. Also, as data is transferred from SCIRXSHF to RD0, the LIN sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from RD0 byte of the LINRD0 register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit is set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1, the checksum will be compared on the byte that is currently being received, which is expected to be the checksum byte. The CC bit will be cleared once the checksum is received. A CE will immediately be flagged if there is a checksum error.

Copyright © 2018, Texas Instruments Incorporated

29.3.4.1.2 Receiving Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit is set to 1. In this mode, LIN sets the RXRDY bit after receiving the programmed number of data in the receive buffer and the checksum field, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that it monitors for the complete frame. Like single-buffer mode, you can use the polling, interrupt, or DMA method to read the data. The received data has to be read from the LINRD0 and LINRD1 registers, based on the number of bytes. For a LENGTH less than or equal to 4, a read from the LINRD0 register clears the RXRDY flag. For a LENGTH greater than 4, a read from the LINRD1 register clears the RXRDY flag. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1 during the reception of the data, then the byte that is received after the reception of the programmed number of data bytes indicated by the LENGTH field is treated as a checksum byte. The CC bit will be cleared once the checksum is received and compared.

29.3.4.2 Transmitting Data

The LIN transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as a LIN function pin. Any value written to the TD0 before the TXENA bit is set to 1 is not transmitted. Both of these control bits allow for the LIN transmitter to be held inactive independently of the receiver.

The ID TX flag is set after a valid LIN ID is received with TX Match. An ID interrupt is generated, if enabled.

29.3.4.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit is cleared to 0. In this mode, LIN waits for data to be written to TD0, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to TD0, the TXRDY bit is set. Additionally, if both TD0 and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the TD0. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the LIN has completed transmission of all pending frames, the SCITXSHF register and the TD0 are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit). If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum byte will be sent after the current byte transmission. The SC bit will be cleared after the checksum byte has been transmitted.

NOTE: The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

Copyright © 2018, Texas Instruments Incorporated

29.3.4.2.2 Transmitting Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit is set to 1. Like single-buffer mode, you can use the polling, interrupt, or DMA method to write the data to be transmitted. The transmitted data has to be written to the LINTD0 and LINTD1 registers, based on the number of bytes. LIN waits for data to be written to Byte 0 (TD0) of the LINTD0 register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically. If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum will be sent after transmission of the last byte of the programmed number of data bytes, indicated by the LENGTH field. The SC bit will be cleared after the checksum byte has been transmitted.

29.4 Low-Power Mode

The SCI/LIN module can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN module. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive. If global low-power mode is requested while the receiver is receiving data, then the SCI/BLIN completes the current reception and then enters the low-power mode, that is, module enters low-power mode only when Busy bit (SCIFLR.3) is cleared.

The BLIN module may enter low-power mode either when there was no activity on the LINRX pin for more than 4s (this can be either a constant recessive or dominant level) or when a Sleep Command frame was received. Once the Timeout flag (SCIFLR.4) was set or once a Sleep Command was received, the POWERDOWN bit (SCIGCR2.0) must be set by the application software to make the module enter local low-power mode. A wakeup signal will terminate the sleep mode of the LIN bus.

NOTE: Enabling Local Low-Power Mode During Receive and Transmit

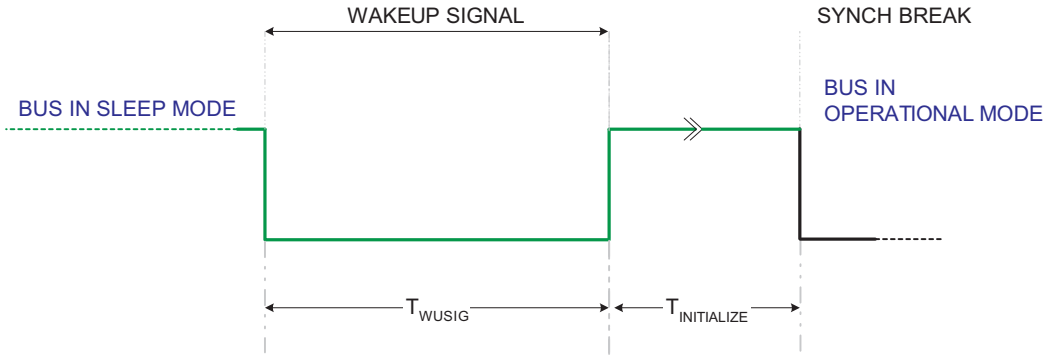
If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI/LIN immediately generates a wake-up interrupt to clear the powerdown bit. Thus, the SCI/LIN is prevented from entering low-power mode and completes the current reception. Otherwise, if the wakeup interrupt is disabled, the SCI/LIN completes the current reception and then enters the low-power mode.

29.4.1 Entering Sleep Mode

In LIN protocol, a sleep command is used to broadcast the sleep mode to all nodes. The sleep command consists of a diagnostic master request frame with identifier 0x3C (60), with the first data field as 0x00. There should be no activity in the bus once all nodes receive the sleep command: the bus is in sleep mode.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and registers. Clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode. If a register is accessed in low-power mode, this access results in enabling the clock to the module for that particular access alone.

Copyright © 2018, Texas Instruments Incorporated



29.4.2 Wakeup

The wakeup interrupt is used to allow the SCI/LIN module to automatically exit low-power mode. A SCI/LIN wakeup is triggered when a low level is detected on the receive RX pin, and this clears the POWERDOWN bit.

NOTE: If the wakeup interrupt is disabled then the SCI/LIN enters low-power mode whenever it is requested to do so, but a low level on the receive RX pin does NOT cause the SCI/LIN to exit low-power mode.

In LIN mode, any node can terminate sleep mode by sending a wakeup signal; see Figure 29-26. A slave node that detects the bus in sleep mode, and with a wakeup request pending, will send a wakeup signal. The wakeup signal is a dominant value on the LIN bus for T_{WUSIG}; this is at least 5 T_{bits} for the LIN bus baud rates. The wakeup signal is generated by sending an 0xF0 byte containing 5 dominant T_{bits} and 5 recessive T_{bits}.

Figure 29-26. Wakeup Signal Generation

$$0.25\text{ms} \le T_{WUSIG} \le 5\text{ms} \quad (51)$$

Assuming a perfect bus with no noise or loading effects, a write of 0xF0 to TD0 will load the transmitter to meet the wakeup signal timing requirement for T_{WUSIG}. Then, setting the GENWU bit will transmit the preloaded value in TD0 for a wakeup signal transmission.

NOTE: The GENWU bit can be set/reset only when SWnRST is set to'1' and the node is in power down mode. The bit will be cleared on a valid synch break detection. A master sending a wakeup request, will exit power down mode upon reception of the wakeup pulse. The bit will be cleared on a SWnRST. This can be used to stop a master from sending further wakeup requests.

The TI TPIC1021 LIN transceiver, upon receiving a wakeup signal, will translate it to the microcontroller for wakeup with a dominant level on the RX pin, or a signal to the voltage regulator. While the POWERDOWN bit is set, if the LIN module detects a recessive-to-dominant edge (falling edge) on the RX pin, it will generate a wakeup interrupt if enabled in the SCISETINT register.

According to LIN protocol 2.0, the TI TPIC1021 LIN transceiver detecting a dominant level on the bus longer than 150 ms will detect it as a wakeup request. The LIN controller's slave is ready to listen to the bus in less than 100 ms ($T_{INITIALIZE}$<100ms) after a dominant-to-recessive edge (end-of-wakeup signal).

Copyright © 2018, Texas Instruments Incorporated

29.4.3 Wakeup Timeouts

The LIN protocol defines the following timeouts for a wakeup sequence. After a wakeup signal has been sent to the bus, all nodes wait for the master to send a header. If no synch field is detected before 150 ms (3,000 cycles at 20 kHz) after wakeup signal is transmitted, a new wakeup is sent by the same node that requested the first wakeup. This sequence is not repeated more than two times. After three attempts to wake up the LIN bus, wakeup signal generation is suspended for a 1.5 s (30,000 cycles at 20 kHz) period after three breaks.

NOTE: To achieve compatibility to LIN1.3 timeout conditions, the MBRS register must be set to assure that the LIN 2.0 (real-time-based) timings meet the LIN 1.3 bit time base. A node triggering the wakeup should set the MBRS register accordingly to meet the targeted time as 128 Tbits × programmed prescaler.

The LIN controller handles the wakeup expiration times defined by the LIN protocol with a hardware implementation.

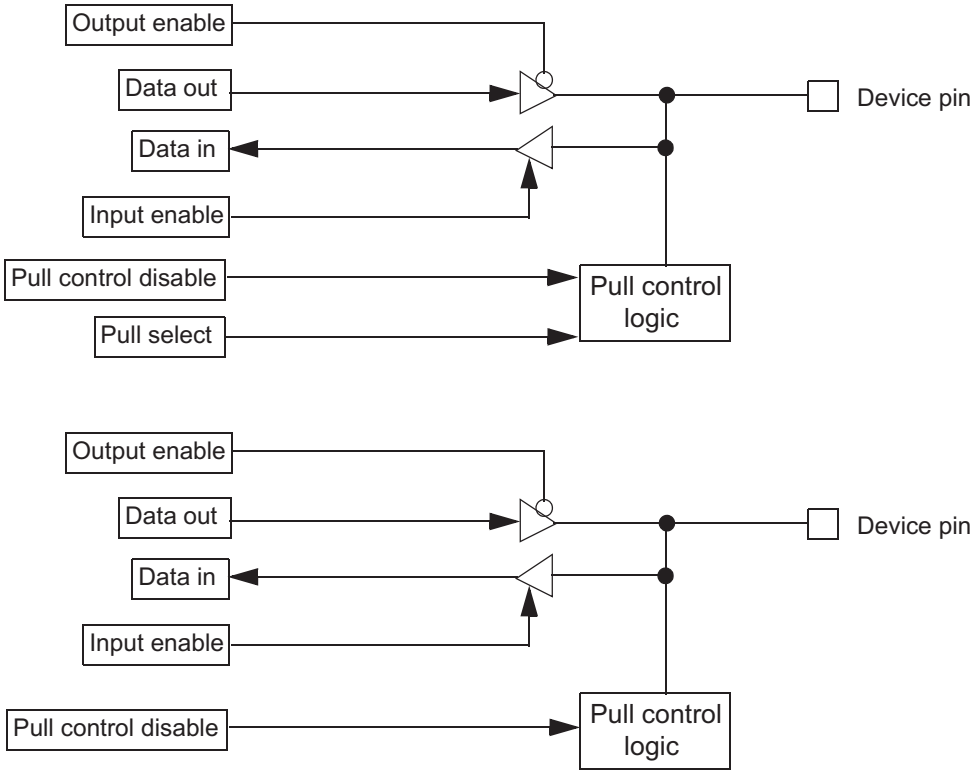
29.5 Emulation Mode

In emulation mode, the CONT bit determines how the SCI/LIN operates when the program is suspended. The SCI/LIN counters are affected by this bit during debug mode. when set, the counters are not stopped and when cleared, the counters are stopped debug mode.

Any reads in emulation mode to a SCI/LIN register will not have any effect on the flags in the SCIFLR register.

NOTE: When emulation mode is entered during the Frame transmission or reception of the frame and CONT bit is not set, Communication is not expected to be successful. The suggested usage is to set CONT bit during emulation mode for successful communication.

Copyright © 2018, Texas Instruments Incorporated



29.6 GPIO Functionality

The following section applies to all device pins that can be configured as functional or general-purpose I/O pins.

29.6.1 GPIO Functionality

Figure 29-27 illustrates the GPIO functionality.

Figure 29-27. GPIO Functionality

29.6.2 Under Reset

The following apply if a device is under reset:

- Pull control. The reset pull control on the pins is enabled.
- Input buffer. The input buffer is enabled.
- Output buffer. The output buffer is disabled.

Copyright © 2018, Texas Instruments Incorporated

29.6.3 Out of Reset

The following apply if the device is out of reset:

- Pull control. The pull control is enabled by clearing the PD (pull control disable) bit in the SCIPIO7 register (Section 29.7.21). In this case, if the PSL (pull select) bit in the SCIPIO8 register (Section 29.7.22) is set, the pin will have a pull-up. If the PSL bit is cleared, the pin will have a pull-down. If the PD bit is set in the control register, there is no pull-up or pull-down on the pin.
- Input buffer. The input buffer is permanently enabled in this device.

NOTE: The pull-disable logic depends on the pin direction. It is independent of whether the device is in I/O or functional mode. If the pin is configured as output or transmit, then the pulls are disabled automatically.

- Output buffer. A pin can be driven as an output pin if the TX DIR bit is set in the pin direction control register (SCIPIO1; Section 29.7.15) AND the open-drain feature is not enabled in the SCIPIO6 register (Section 29.7.20).

29.6.4 Open-Drain Feature Enabled on a Pin

The following apply if the open-drain feature is enabled on a pin:

- The output buffer is enabled if a low signal is being driven on to the pin.
- The output buffer is disabled (the direction control signal DIR is internally forced low) if a high signal is being driven on to the pin.

NOTE: The open-drain feature is available only in I/O mode (SCIPIO0; Section 29.7.14).

29.6.5 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 29-9.

Table 29-9. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins [1]

Device under Reset?	Pin Direction (DIR) [2]	Pull Disable (PULDIS) [3]	Pull Select (PULSEL) [4]	Pull Control	Output Buffer	Input Buffer
Yes	X	X	X	Enabled	Disabled	Enabled
No	0	0	0	Pull down	Disabled	Enabled
No	0	0	1	Pull up	Disabled	Enabled
No	0	1	0	Disabled	Disabled	Enabled
No	0	1	1	Disabled	Disabled	Enabled
No	1	X	X	Disabled	Enabled	Enabled

(1) X = Don't care
(2) DIR = 0 for input, = 1 for output
(3) PULDIS = 0 for enabling pull control, = 1 for disabling pull control
(4) PULSEL= 0 for pull-down functionality, = 1 for pull-up functionality

Copyright © 2018, Texas Instruments Incorporated

29.7 SCI/LIN Control Registers

The SCI/LIN module registers are based on the SCI registers, with added functionality registers enabled by the LIN MODE bit in the SCIGCR1 register.

These registers are accessible in 8-, 16-, and 32-bit reads or writes. The SCI/LIN is controlled and accessed through the registers listed in Table 29-10. Among the features that can be programmed are the LIN protocol mode, communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration. The base address for the control registers is FFF7 E400h for LIN1/SCI1 and FFF7 E600h for LIN2/SCI2.

Table 29-10. SCI/LIN Control Registers

LEGEND: R = Read only; R/WP = Read/Write in privileged mode only; *-n* = value after reset

Table 29-11. SCI Global Control Register 0 (SCIGCR0) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reads return 0. Writes have no effect.
0	RESET		This bit resets the SCI/LIN module. This bit is effective in SCI and LIN mode.
		0	SCI/LIN module is in reset.
		1	SCI/LIN module is out of reset.
			Note: Read/Write in privileged mode only.

29.7.2 SCI Global Control Register 1 (SCIGCR1)

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI. Figure 29-29 and Table 29-12 illustrate this register.

Figure 29-29. SCI Global Control Register 1 (SCIGCR1) (offset = 04h)

31						26	25	24

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; WC = Write in SCI-compatible mode only; -*n* = value after reset

Table 29-12. SCI Global Control Register 1 (SCIGCR1) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reads return 0. Writes have no effect.
25	TXENA		Transmit enable. This bit is effective in LIN and SCI modes. Data is transferred from SCITD, or the TDy (with y=0, 1,...7) buffers in LIN mode to the SCITXSHF shift out register only when the TXENA bit is set.
		0	Transfers from SCITD or TDy to SCITXSHF are disabled.
		1	Transfers from SCITD or TDy to SCITXSHF are enabled.
			Note: Data written to SCITD or the transmit multi-buffer before TXENA is set is not transmitted. If TXENA is cleared while transmission is ongoing, the data previously written to SCITD is sent (including the checksum byte in LIN mode).
24	RXENA		Receive enable. This bit is effective in LIN and SCI modes. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD or the receive multi-buffers.
		0	The receiver will not transfer data from the shift buffer to the receive buffer or multi-buffers.
		1	The receiver will transfer data from the shift buffer to the receive buffer or multi-buffers.
			Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA.
			Note: If RXENA is cleared before a frame is completely received, the data from the frame is not transferred into the receive buffer.
			Note: If RXENA is set before a frame is completely received, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not guaranteed to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame.
23-18	Reserved	0	Reads return 0. Writes have no effect.
17	CONT		Continue on suspend. This bit is effective in LIN and SCI modes. This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI/LIN operates when the program is suspended. The SCI/LIN counters are affected by this bit: when the bit is set the counters are not stopped, when the bit is cleared the counters are stopped during debug mode.
		0	When debug mode is entered, the SCI/LIN state machine is frozen. Transmissions and LIN counters are halted and resume when debug mode is exited.
		1	When debug mode is entered, the SCI/LIN continues to operate until the current transmit and receive functions are complete.

Copyright © 2018, Texas Instruments Incorporated

Table 29-12. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
16	LOOP BACK		Loopback bit. This bit is effective in LIN and SCI modes. The self-checking option for the SCI/LIN can be selected with this bit. If the LINITX and LINRX pins are configured with SCI/LIN functionality, then the LINTX pin is internally connected to the LINRX pin. Externally, during loop back operation, the LINTX pin outputs a high value and the LINRX pin is in a high-impedance state. If this bit value is changed while the SCI/LIN is transmitting or receiving data, errors may result.
		0	Loop back mode is disabled.
		1	Loop back mode is enabled.
15-14	Reserved	0	Reads return 0. Writes have no effect.
13	STOP EXT FRAME		Stop extended frame communication. This bit is effective in LIN mode only. This bit can be written only during extended frame communication. When the extended frame communication is stopped, this bit is cleared automatically.
		0	This bit has no effect.
		1	Extended frame communication will be stopped when current frame transmission/reception is completed.
12	HGEN CTRL		HGEN control. This bit is effective in LIN mode only. This bit controls the type of mask filtering comparison.
		0	ID filtering using the ID-BYTE field in LIN Identification Register (LINID) occurs.
			Mask of FFh in LIN Mask Register (LINMASK) register will result in no match.
		1	ID filtering uses ID-SlaveTask BYTE (recommended).
			Mask of FFh in LIN Mask Register (LINMASK) register will result in ALWAYS match.
			Note: For software compatibility with future LIN modules the HGEN CTRL bit must be set to 1, the RX ID MASK must be set to FFh and the TX ID MASK must be set to FFh.
11	CTYPE		Checksum type. This bit is effective in LIN mode only. This bit controls the type of checksum to be used: classic or enhanced.
		0	Classic checksum is used.
		1	Enhanced checksum is used.
10	MBUF MODE		Multi-buffer mode. This bit is effective in LIN and SCI modes. This bit controls receive/transmit buffer usage, that is, whether the RX/TX multi-buffers are used or a single register, RD0/TD0, is used.
		0	The multi-buffer mode is disabled.
		1	The multi-buffer mode is enabled.
9	ADAPT		Adapt. This mode is effective in LIN mode only. This bit has an effect during the detection of the synch field. Two LIN protocol bit rate modes could be enabled with this bit according to the node capability file definition: automatic or select. The software and network configuration will decide which of these two modes are enabled. When this bit is cleared, the LIN 2.0 protocol fixed bit rate should be used. If the ADAPT bit is set, a SCI/LIN slave node detecting the baud rate will compare it to the prescalers in BRS register and update it if they are different. The BRS register will be updated with the new value. If this bit is not set there will be no adjustment to the BRS register.
		0	Automatic baud rate adjustment is disabled.
		1	Automatic baud rate adjustment is enabled.
8	SLEEP		SCI sleep. This bit is effective in SCI mode only. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI/LIN out of sleep mode.
		0	Sleep mode is disabled.
		1	Sleep mode is enabled.
			Note: The receiver still operates when the SLEEP bit is set; however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition.
			Note: The SLEEP bit is *not* automatically cleared when an address byte is detected.
			See Section 29.2.5.1 for more information on using the SLEEP bit for multiprocessor communication.

Table 29-12. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
7	SWnRST		Software reset (active low). This bit is effective in LIN and SCI modes.
		0	The SCI/LIN is in its reset state; no data will be transmitted or received. Writing a 0 to this bit initializes the SCI/LIN state machines and operating flags as defined in Table 29-13 and Table 29-14. All affected logic is held in the reset state until a 1 is written to this bit.
		1	The SCI/LIN is in its ready state; transmission and reception can be done. After this bit is set to 1, the configuration of the module should not change.
			Note: The SCI/LIN should only be configured while SWnRST = 0.
6	LIN MODE		LIN mode. This bit is effective in LIN and SCI mode. This bit controls the module mode of operation.
		0	LIN mode is disabled; SCI mode is enabled.
		1	LIN mode is enabled; SCI mode is disabled.
5	CLOCK		SCI internal clock enable. The CLOCK bit determines the source of the module clock on the SCICLK pin. It also determines whether a LIN node is a slave or master.
			SCI mode:
		0	The external SCICLK is the clock source.
			Note: If an external clock is selected, then the internal baud rate generator and baud rate registers are bypassed. The maximum frequency allowed for an externally sourced SCI clock is VCLK/16.
		1	The internal SCICLK is the clock source.
			LIN mode:
		0	The node is in slave mode.
		1	The node is in master mode.
4	STOP		SCI number of stop bits per frame. This bit is effective in SCI mode only.
		0	One stop bit is used.
		1	Two stop bits are used.
			Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.
3	PARITY		SCI parity odd/even selection. This bit is effective in SCI mode only. If the PARITY ENA bit is set, PARITY designates odd or even parity.
		0	Odd parity is used.
		1	Even parity is used.
			The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.
			For odd parity, the SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.
			For even parity, the SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.
2	PARITY ENA		Parity enable. This bit enables or disables the parity function.
			SCI or buffered SCI mode:
		0	Parity is disabled. No parity bit is generated during transmission or is expected during reception.
		1	Parity is enabled. A parity bit is generated during transmission and is expected during reception.
			LIN mode:
		0	ID field parity verification is disabled.
		1	ID field parity verification is enabled.
1	TIMING MODE		SCI timing mode bit. This bit is effective in SCI mode only. it selects the SCI timing mode.
		0	Synchronous timing is used.
		1	Asynchronous timing is used.

Table 29-12. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
0	COMM MODE		SCI/LIN communication mode bit. In compatibility mode it selects the SCI communication mode. In LIN mode it selects length control option for ID-field bits ID4 and ID5.
			SCI mode:
		0	Idle-line mode is used.
		1	Address-bit mode is used.
			LIN mode:
		0	ID4 and ID5 are not used for length control.
		1	ID4 and ID5 are used for length control.

29.7.3 SCI Global Control Register 2 (SCIGCR2)

The SCIGCR2 register is used to send or compare a checksum byte during extended frames, to generate a wakeup and for low-power mode control of the LIN module. Figure 29-30 and Table 29-15 illustrate this register.

Figure 29-30. SCI Global Control Register 2 (SCIGCR2) (offset = 08h)

31	18	17	16
Reserved		CC	SC
R-0		R/WL-0	R/WL-0

15	9	8	7	1	0
Reserved		GEN WU	Reserved		POWERDOWN
R-0		R/W-0	R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; -*n* = value after reset

Table 29-15. SCI Global Control Register 2 (SCIGCR2) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads return 0. Writes have no effect.
17	CC		Compare checksum. LIN mode only. This bit is used by the receiver for extended frames to trigger a checksum compare. You initiate this transaction by writing a one to this bit. CC bit has to be set only after RX_RDY flag is set for the last received data. In non-multi-buffer mode, when the CC bit is set, the checksum will be compared on the byte that is expected to be the checksum byte. During multi-buffer mode, the following scenarios are associated with the CC bit: a) If the CC bit is set during the reception of the data, then the byte that is received after the reception of the programmed number of data bytes as indicated by SCIFORMAT[18:16] is treated as a checksum byte. b) If the CC bit is set during the idle period (that is, during the inter-frame space), then the immediate next byte will be treated as a checksum byte. c) CC bit will be auto cleared after the checkbyte has been received and compared. Checksum reception is not guaranteed if CC bit is write cleared by software during the checksum reception. See Section 29.3.1.6 for more details.
		0	No checksum compare will occur.
		1	Compare checksum on expected checksum byte.
16	SC		Send checksum byte. This bit is effective in LIN mode only. This bit is used by the transmitter with extended frames to send a checksum byte. In non-multi-buffer mode, the checksum byte will be sent after the current byte transmission. In multi-buffer mode, the checksum byte will be sent after the last byte count, indicated by the SCIFORMAT[18:16]). See Section 29.3.1.6 for more details. This byte will be cleared after the checksum byte has been transmitted. In non-multi-buffer mode, the checksum byte will be sent after the current byte transmission. During multi-buffer mode, the following scenarios are associated with the SC bit: a) The checkbyte will be sent after the last byte count, indicated by the SCIFORMAT[18:16]). b) Checksum will not be sent if SC is set before transmitting the very first byte(that is, during interframe space). c) SC bit will be auto cleared after the checkbyte has been transmitted. Checksum transmission is not guaranteed if SC bit is write cleared by software during the checksum transmission. See Section 29.3.1.6 for more details.
		0	No checksum byte will be sent.
		1	A checksum byte will be sent.
15-9	Reserved	0	Reads return 0. Writes have no effect.
8	GEN WU		Generate wakeup signal. This bit is effective in LIN mode only. This bit controls the generation of a wakeup signal, by transmitting the TDO buffer value. The LIN protocol specifies that this signal should be a dominant for T_{WUSIG}. This bit is cleared on reception of a valid synch break.
		0	No wakeup signal will be generated.
		1	The TDO buffer value will be transmitted for a wakeup signal. The bit will be cleared on a SWnRST.
7-1	Reserved	0	Reads return 0. Writes have no effect.

Copyright © 2018, Texas Instruments Incorporated

Table 29-15. SCI Global Control Register 2 (SCIGCR2) Field Descriptions (continued)

Bit	Field	Value	Description
0	POWERDOWN		Power down. This bit is effective in LIN or SCI mode. When this bit is set, the SCI/LIN module attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wakeup interrupt is disabled, then the SCI/LIN will delay entering low-power mode until the reception is completed. In LIN mode, you may set the POWERDOWN bit after receiving a sleep command or on idle bus detection (more than 4 seconds). See Section 29.4 for more information on low-power mode.
		0	The SCI/LIN module is in normal operation.
		1	The SCI/LIN module enters local low-power mode.

Table 29-16. SCI Set Interrupt Register (SCISETINT) Field Descriptions

Bit	Field	Value	Description
31	SET BE INT		Set bit error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a bit error.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
30	SET PBE INT		Set physical bus error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a physical bus error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
29	SET CE INT		Set checksum-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a checksum error.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
28	SET ISFE INT		Set inconsistent-synch-field-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is an inconsistent synch field error.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
27	SET NRE INT		Set no-response-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a no-response error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.

Copyright © 2018, Texas Instruments Incorporated

Table 29-16. SCI Set Interrupt Register (SCISETINT) Field Descriptions (continued)

Bit	Field	Value	Description
26	SET FE INT		Set framing-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a framing error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
25	SET OE INT		Set overrun-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when an overrun error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
24	SET PE INT		Set parity interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a parity error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
23-19	Reserved	0	Reads return 0. Writes have no effect.
18	SET RX DMA ALL		Set receive DMA all. This bit is effective in SCI-compatible mode only. This bit determines if a separate interrupt is generated for the address frames sent in multiprocessor communications. When this bit is 0, RX interrupt requests are generated for address frames and DMA requests are generated for data frames. When this bit is 1, RX DMA requests are generated for both address and data frames.
		0	*Read:* The DMA request is disabled for address frames (the receive interrupt request is enabled for address frames). *Write:* No effect.
		1	*Read and write:* The DMA request is enabled for address and data frames.
17	SET RX DMA		Set receiver DMA. This bit is effective in LIN or SCI-compatible mode. To enable receiver DMA requests, this bit must be set. If it is cleared, interrupt requests are generated depending on SET RX INT bit (SCISETINT).
		0	*Read:* The DMA request is disabled. *Write:* No effect.
		1	*Read and write:* The DMA request is enabled for address and data frames.
16	SET TX DMA		Set transmit DMA. This bit is effective in LIN or SCI-compatible mode. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on SET TX INT bit (SCISETINT).
		0	*Read:* Transmit DMA request is disabled. *Write:* No effect.
		1	*Read and write:* Transmit DMA request is enabled.
15-14	Reserved	0	Reads return 0. Writes have no effect.
13	SET ID INT		Set identification interrupt. This bit is effective in LIN mode only. This bit is set to enable an interrupt when a valid matching identifier is received. See Section 29.3.1.9 for more details.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
12-10	Reserved	0	Reads return 0. Writes have no effect.
9	SET RX INT		Receiver interrupt enable. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.

Copyright © 2018, Texas Instruments Incorporated

Table 29-16. SCI Set Interrupt Register (SCISETINT) Field Descriptions (continued)

Bit	Field	Value	Description
8	SET TX INT		Set transmitter interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
7	SET TOA3WUS INT		Set timeout after three wakeup signals interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when a timeout occurs after three wakeup signals have been sent.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
6	SET TOAWUS INT		Set timeout after wakeup signal interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when a timeout occurs after one wakeup signal has been sent.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
5	Reserved	0	Reads return 0. Writes have no effect.
4	SET TIMEOUT INT		Set timeout interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when there is no LIN bus activity (bus idle) for at least four seconds.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
3-2	Reserved	0	Reads return 0. Writes have no effect.
1	SET WAKEUP INT		Set wake-up interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a wakeup interrupt and thereby exit low-power mode. If enabled, the wakeup interrupt is asserted when local low-power mode is requested while the receiver is busy or if a low level is detected on the LINRX pin during low-power mode.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
0	SET BRKDT INT		Set break-detect interrupt. This bit is effective in SCI-compatible mode only. Setting this bit enables the SCI/LIN to generate an error interrupt if a break condition is detected on the LINRX pin.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.

Table 29-17. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions

Bit	Field	Value	Description
31	CLR BE INT		Clear bit error interrupt. This bit is effective in LIN mode only. This bit disables the bit error interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
30	CLR PBE INT		Clear physical bus error interrupt. This bit is effective in LIN mode only. This bit disables the physical-bus error interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
29	CLR CE INT		Clear checksum-error interrupt. This bit is effective in LIN mode only. This bit disables the checksum interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
28	CLR ISFE INT		Clear inconsistent-synch-field-error (ISFE) interrupt. This bit is effective in LIN mode only. This bit disables the ISFE interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.

Table 29-17. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions (continued)

Bit	Field	Value	Description
27	CLR NRE INT		Clear no-response-error interrupt. This bit is effective in LIN mode only. This bit disables the NRE interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
26	CLR FE INT		Clear framing-error interrupt. This bit is effective in LIN or SCI mode. This bit disables the framing-error interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
25	CLR OE INT		Clear overrun-error interrupt. This bit is effective in LIN or SCI mode. This bit disables the SCI/LIN overrun error interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
24	CLR PE INT		Clear parity interrupt. This bit is effective in LIN or SCI mode. This bit disables the parity error interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
23-19	Reserved	0	Reads return 0. Writes have no effect.
18	CLR RX DMA ALL		Clear receive DMA all. This bit is effective in SCI mode only. This bit clears the receive DMA request for address frames when set. Only receive data frames generate a DMA request.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The receive DMA request for address and data frames is enabled. *Write:* The receive DMA request for address and data frames is disabled.
17	CLR RX DMA		Clear receive DMA request. This bit is effective in LIN or SCI mode. This bit disables the receive DMA request when set.
		0	*Read:* The receive DMA request is disabled. *Write:* No effect.
		1	*Read:* The receive DMA request is enabled. *Write:* The receive DMA request for is disabled.
16	CLR TX DMA		Clear transmit DMA request. This bit is effective in LIN or SCI mode. This bit disables the transmit DMA request when set.
		0	*Read:* The transmit DMA request is disabled. *Write:* No effect.
		1	*Read:* The transmit DMA request is enabled. *Write:* The transmit DMA request for is disabled.
15-14	Reserved	0	Reads return 0. Writes have no effect.
13	CLR ID INT		Clear ID interrupt. This bit is effective in LIN mode only. This bit disables the ID interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.

Table 29-17. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions (continued)

Bit	Field	Value	Description
12-10	Reserved	0	Reads return 0. Writes have no effect.
9	CLR RX INT		Clear receiver interrupt. This bit is effective in LIN or SCI mode. This bit disables the receiver interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
8	CLR TX INT		Clear transmitter interrupt. This bit is effective in LIN or SCI mode. This bit disables the transmitter interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
7	CLR TOA3WUS INT		Clear timeout after three wakeup signals interrupt. This bit is effective in LIN mode only. This bit disables the timeout after three wakeup signals interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
6	CLR TOAWUS INT		Clear timeout after wakeup signal interrupt. This bit is effective in LIN mode only. This bit disables the timeout after one wakeup signal interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
5	Reserved	0	Reads return 0. Writes have no effect.
4	CLR TIMEOUT INT		Clear timeout interrupt. This bit is effective in LIN mode only. This bit disables the timeout (LIN bus idle) interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
3-2	Reserved	0	Reads return 0. Writes have no effect.
1	CLR WAKEUP INT		Clear wake-up interrupt. This bit is effective in LIN or SCI-compatible mode. This bit disables the wakeup interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
0	CLR BRKDT INT		Clear break-detect interrupt. This bit is effective in SCI-compatible mode only. This bit disables the break-detect interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.

Table 29-20. SCI Flags Register (SCIFLR) Field Descriptions

Bit	Field	Value	Description
31	BE		Bit error flag. This bit is effective in LIN mode only. This bit is set when a bit error has occurred. This is detected by the internal bit monitor. See Section 29.3.1.8 for more information. The bit error flag is cleared by any of the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • On reception of a new synch break • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No error has been detected since this bit was last cleared. *Write:* No effect.
		1	*Read:* An error has been detected since this bit was last cleared. *Write:* The bit is cleared to 0.
30	PBE		Physical bus error flag. This bit is effective in LIN mode only. This bit is set when a physical bus error has been detected by the bit monitor in TED. See Section 29.3.1.8 for more information. The physical bus error flag is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • On reception of a new synch break • Reading the corresponding interrupt offset in SCIINTVECT0/1 **Note: The PBE will only be flagged, if no Synch Break can be generated (for example, because of a bus shortage to VBAT) or if no Synch Break Delimiter can be generated (for example, because of a bus shortage to GND).**
		0	*Read:* No error has been detected since this bit was last cleared. *Write:* No effect.
		1	*Read:* An error has been detected since this bit was last cleared. *Write:* The bit is cleared to 0.

Copyright © 2018, Texas Instruments Incorporated

Table 29-20. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
29	CE		Checksum error flag. This bit is effective in LIN mode only. This bit is set when a checksum error has been detected by a receiving node. This error is detected by the TED logic. See Section 29.3.1.8 for more information. The type of checksum to be used depends on the CTYPE bit in SCIGCR1. The checksum error flag is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reception of a new synch break • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No error has been detected since this bit was last cleared. *Write:* No effect.
		1	*Read:* An error has been detected since this bit was last cleared. *Write:* The bit is cleared to 0.
28	ISFE		Inconsistent synch field error flag. This bit is effective in LIN mode only. This bit is set when an inconsistent synch field error has been detected by the synchronizer during header reception. See Section 29.3.1.5.2 for more information. The inconsistent synch field error flag is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reception of a new synch break • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No inconsistent synch field error has been detected. *Write:* No effect.
		1	*Read:* An inconsistent synch field error has been detected. *Write:* The bit is cleared to 0.
27	NRE		No-response error flag. This bit is effective in LIN mode only. This bit is set when there is no response to a master's header completed within TFRAME_MAX. This timeout period is applied for message frames of known length (identifiers 0 to 61). This error is detected by the synchronizer. See Section 29.3.1.7 for more information. The no-response error flag is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reception of a new synch break • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No no-response error has been detected since the last clear. *Write:* No effect.
		1	*Read:* A no-response error has been detected. *Write:* The bit is cleared to 0.

Copyright © 2018, Texas Instruments Incorporated

Table 29-20. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
26	FE		Framing error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatibility mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI/LIN to generate an error interrupt if the SET FE INT bit is set in the register SCISETINT. The framing error flag is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 • Reception of a new character/frame, depending on whether the module is in SCI compatible or LIN mode In multi-buffer mode the frame is defined in the SCIFORMAT register.
		0	*Read:* No framing error has been detected since the last clear. *Write:* No effect.
		1	*Read:* A framing error has been detected since the last clear. *Write:* The bit is cleared to 0.
25	OE		Overrun error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD or the RDy buffers in LINRD0 and LINRD1. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit = 1. The OE flag is reset by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No overrun error has been detected since the last clear. *Write:* No effect.
		1	*Read:* An overrun error has been detected. *Write:* The bit is cleared to 0.
24	PE		Parity error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. If the parity function is disabled (SCIGCR[2] = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit = 1. The PE bit is reset by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reception of a new character or frame, depending on whether the module is in SCI compatible or LIN mode, respectively. • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No parity error has been detected since the last clear. *Write:* No effect.
		1	*Read:* A parity error has been detected. *Write:* The bit is cleared to 0.
23-15	Reserved	0	Reads return 0. Writes have no effect.

Table 29-20. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
14	ID RX		Identifier on receive flag. This bit is effective in LIN mode only. This flag is set once an identifier is received with an receive match and no ID-parity error. See Section 29.3.1.9 for more details. This flag indicates that a new valid identifier has been received on an RX match. This bit is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the LINID register • Reception of a new synch break • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No valid ID has been received since the last clear. *Write:* No effect.
		1	*Read:* A valid ID RX has been received in LINID[23:16] on an RX match. *Write:* The bit is cleared to 0.
13	ID TX		Identifier on transmit flag. This bit is effective in LIN mode only. This flag is set when an identifier is received with a transmit match and no ID-parity error. See Section 29.3.1.9 for more details. This flag indicates that a new valid identifier has been received on a TX match. This bit is cleared by the following: • Setting the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the LINID register • Receiving a new synch break • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No valid ID has been received since the last clear. *Write:* No effect.
		1	*Read:* A valid ID TX has been received in LINID[23:16] on an TX match. *Write:* The bit is cleared to 0.
12	RX WAKE		Receiver wakeup detect flag. This bit is effective in SCI-compatible mode only. The SCI sets this bit to indicate that the data currently in SCIRD is an address. RX WAKE is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Upon receipt of a data frame.
		0	The data in SCIRD is not an address.
		1	The data in SCIRD is an address.
11	TX EMPTY		Transmitter empty flag. This flag indicates the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF) are empty. In multi-buffer mode, this flag indicates the TDx registers and shift register (SCITXSHF) are empty. In non-multi-buffer mode, this flag indicates the LINTD0 byte and the shift register (SCITXSHF) are empty. **Note: The RESET bit, an active SWnRST (SCIGCR1[7]) or a system reset sets this bit. This bit does not cause an interrupt request.** *SCI mode or LIN non-multi-buffer mode:*
		0	Transmitter buffer or shift register (or both) are loaded with data.
		1	Transmitter buffer and shift registers are both empty.
			In LIN mode using multi-buffer mode:
		0	Multi-buffer or shift register (or all) are loaded with data
		1	Multi-buffer and shift registers are all empty.

Copyright © 2018, Texas Instruments Incorporated

Table 29-20. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
10	TX WAKE		Transmitter wakeup method select. This bit is effective in SCI mode only. The TX WAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. **Note: TX WAKE is not cleared by the SWnRST bit.** *Address-bit mode*:
		0	Frame to be transmitted will be data (address bit = 0).
		1	Frame to be transmitted will be an address (address bit = 1).
			Idle-line mode:
		0	The frame to be transmitted will be data.
		1	The following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).
9	RX RDY		Receiver ready flag. In SCI-compatible mode, the receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU. In *LIN mode,* RX RDY is set once a valid frame is received in multi-buffer mode, a valid frame being a message frame received with no errors. In *non-multi-buffer mode,* RX RDY is set for each received byte and will be set for the last byte of the frame if there are no errors. The SCI/LIN generates a receive interrupt when RX RDY flag bit is set if the SET RX INT bit is set (SCISETINT[9]); RX RDY is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the SCIRD register in compatibility mode • Reading the last data byte RDy of the response in LIN mode **Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.**
		0	*Read:* No new data is in SCIRD. *Write:* No effect.
		1	*Read:* New data is ready to be read from SCIRD. *Write:* The bit is cleared to 0.
8	TX RDY		Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer(s) register(s) (SCITD in compatibility mode and LINTD0/LINTD1 in multi-buffer mode) are ready to get another character from a CPU write. *In SCI,* writing data to SCITD automatically clears this bit. In *LIN mode,* this bit is cleared once byte 0 (TD0) is written to LINTD0. This bit is set after the data of the TX buffer is shifted into the SCITXSHF register. This event can trigger a transmit interrupt after data is copied to the TX shift register SCITXSHF, if the SET TX INT is set. **Note:** **1) TXRDY is also set to 1 either by setting of the RESET bit, enabling SWnRST or by a system reset.** **2) The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.** **3) The transmit interrupt request can be eliminated until the next series of data written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit.** *SCI mode:*
		0	SCITD is full.
		1	SCITD is ready to receive the next character.
			LIN mode:
		0	Multi-buffers are full.
		1	Multi-buffers are ready to receive the next character.
			For more information on transmit interrupt handling, see the SCI document for compatibility mode and Section 29.3.1.9 for LIN mode.

Table 29-20. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
7	TOA3WUS		Timeout after three wakeup signals flag. This bit is effective in LIN mode only. This flag is set if there is no synch break received after three wakeup signals and a period of 1.5 seconds has passed. Such expiration time is used before issuing another round of wakeup signals. This bit is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 See Section 29.4.3 for more information.
		0	*Read:* No timeout occurred after three wakeup signals. *Write:* No effect.
		1	*Read:* Timeout occurred after three wakeup signals and 1.5 seconds time. *Write:* The bit is cleared to 0.
6	TOAWUS		Timeout after wakeup signal flag. This bit is effective in LIN mode only. This bit is set if there is no synch break received after a wakeup signal has been sent. A minimum of 150 ms expiration time is used before issuing another wakeup signal. This bit is cleared by the following: • Setting the SWnRST bit • Setting of the RESET bit • A system reset occurring • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 See Section 29.4.3 for more information.
		0	*Read:* No timeout occurred after one wakeup signal (150 ms). *Write:* No effect.
		1	*Read:* Timeout occurred after one wakeup signal. *Write:* The bit is cleared to 0.
5	Reserved	0	Reads return 0. Writes have no effect.
4	TIMEOUT		LIN bus idle timeout flag. This bit is effective in LIN mode only. This bit is set earliest after at least four seconds of bus inactivity. Bus inactivity is defined as no transactions between recessive and dominant (and vice versa). This bit is cleared by the following: • Setting the SWnRST bit • Setting of the RESET bit • A system reset occurring • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 See Section 29.3.1.7 for more information.
		0	*Read:* No bus idle has been detected since this bit was last cleared. *Write:* No effect.
		1	*Read:* A LIN bus idle has been detected. *Write:* The bit is cleared to 0.
3	BUSY		Bus busy flag. This bit is effective in LIN mode and SCI-compatible mode. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the SCI/LIN clears the BUSY bit. If SET WAKEUP INT is set and power down is requested while this bit is set, the SCI/LIN automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI/LIN receiver, but this bit can also be cleared by the following: • Setting the SWnRST bit • Setting of the RESET bit • A system reset occurring
		0	The receiver is not currently receiving a frame.
		1	The receiver is currently receiving a frame.

Copyright © 2018, Texas Instruments Incorporated

Table 29-20. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
2	IDLE		SCI receiver in idle state. This bit is effective in SCI-compatible mode only. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters the idle state if one of the following events occurs: • A system reset • An SCI software reset • A power down • The RX pin is configured as a general I/O pin
		0	The idle period has been detected; the SCI is ready to receive.
		1	The idle period has not been detected; the SCI will not receive any data.
1	WAKEUP		Wakeup flag. This bit is effective in LIN mode only. This bit is set by the SCI/LIN when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISETINT[2]) is set. It is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 For compatibility mode, see the SCI document for more information on low-power mode.
		0	*Read:* The module will not wake up from power-down mode. *Write:* No effect.
		1	*Read:* Wake up from power-down mode. *Write:* The bit is cleared to 0.
0	BRKDT		SCI break-detect flag. This bit is effective in SCI-compatible mode only. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the LINRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the SET BRKDT INT bit is set. The BRKDT bit is reset by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No break condition has been detected since the last clear. *Write:* No effect.
		1	*Read:* A break condition has been detected. *Write:* The bit is cleared to 0.

Table 29-21. SCI Interrupt Vector Offset 0 (SCIINTVECT0) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reads return 0. Writes have no effect.
4-0	INVECT0	0-1Fh	Interrupt vector offset for INT0. This register indicates the offset for interrupt line INT0. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. See Table 29-4 for a list of the interrupts. **Note: The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register).**

29.7.10 SCI Interrupt Vector Offset 1 (SCIINTVECT1)

Figure 29-37 and Table 29-22 illustrate this register.

Table 29-22. SCI Interrupt Vector Offset 1 (SCIINTVECT1) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reads return 0. Writes have no effect.
4-0	INVECT1	0-1Fh	Interrupt vector offset for INT1. This register indicates the offset for interrupt line INT1. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. See Table 29-4 for list of interrupts. **Note: The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register).**

29.7.11 SCI Format Control Register (SCIFORMAT)

Figure 29-38 and Table 29-23 illustrate this register.

Figure 29-38. SCI Format Control Register (SCIFORMAT) (offset = 28h)

31	19	18	16
Reserved		LENGTH	
R-0		R/W-0	

15	3	2	0
Reserved		CHAR	
R-0		R/WC-0	

LEGEND: R/W = Read/Write; R = Read only; WC = Write in SCI-compatible mode only; -*n* = value after reset

Table 29-23. SCI Format Control Register (SCIFORMAT) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reads return 0. Writes have no effect.
18-16	LENGTH	0-3h	Frame length control bits. In *LIN mode*, these bits indicate the number of bytes in the response field from 1 to 8 bytes. In *buffered SCI mode*, these bits indicate the number of characters, with the number of bits per character specified in CHAR (SCIFORMAT[2:0]). When these bits are used to indicate LIN response length (SCIGCR1[0] = 1), then when there is an ID RX match, this value should be updated with the expected length of the response. In buffered SCI mode, these bits indicate the transmitter/receiver format for the number of characters: 1 to 8. There can be up to eight characters with eight bits each.
		0	The response field has 1 byte/character.
		1h	The response field has 2 bytes/characters.
		2h	The response field has 3 bytes/characters.
		3h	The response field has 4 bytes/characters.
		4h	The response field has 5 bytes/characters.
		5h	The response field has 6 bytes/characters.
		6h	The response field has 7 bytes/characters.
		7h	The response field has 8 bytes/characters.
15-3	Reserved	0	Reads return 0. Writes have no effect.
2-0	CHAR	0-7h	Character length control bits. These bits are effective in non-buffered SCI and buffered SCI modes only. These bits set the SCI character length from 1 to 8 bits. **In non-buffered SCI and buffered SCI mode, when data of fewer than eight bits in length is received, it is left justified in SCIRD/RDy and padded with trailing zeros. Data read from the SCIRD should be shifted by software to make the received data right justified.** **Data written to the SCITD should be right justified but does not need to be padded with leading zeros.**
		0	The character is 1 bit long.
		1h	The character is 2 bits long.
		2h	The character is 3 bits long.
		3h	The character is 4 bits long.
		4h	The character is 5 bits long.
		5h	The character is 6 bits long.
		6h	The character is 7 bits long.
		7h	The character is 8 bits long.

R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 29-24. Baud Rate Selection Register (BRS) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reads return 0. Writes have no effect.
30-28	U	0-2h	SCI/LIN super fractional divider selection. These bits are effective in LIN or SCI asynchronous mode. These bits are an additional fractional part for the baud rate specification. These bits allow a super-fine tuning of the fractional baud rate with seven more intermediate values for each of the M fractional divider values. See Section 29.3.1.4.1 for more details.
27-24	M	0-3h	SCI/LIN 4-bit fractional divider selection. These bits are effective in LIN or SCI asynchronous mode. These bits are used to select a baud rate for the SCI/LIN module, and they are a fractional part for the baud rate specification. The M divider allows fine-tuning of the baud rate over the P prescaler with 15 additional intermediate values for each of the P integer values. See Section 29.3.1.4.1 for more details.
23-0	PRESCALER P	0-FF FFFFh	These bits are used to select a baud rate for the SCI/LIN module. These bits are effective in LIN mode and SCI compatibility. The SCI/LIN has an internally generated serial clock determined by the VCLK and the prescalers P and M in this register. The LIN uses the 24-bit integer prescaler P value of this register to select one of over 16,700,000. The additional 4-bit fractional divider M refines the baud rate selection PRESCALER[27:24]. **NOTE: In LIN mode, ONLY the asynchronous mode and baud rate values are used.** The baud rate can be calculated using the following formulas: $\text{Asynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{16\left(\text{P} + 1 + \frac{\text{M}}{16}\right)}\right)$ (52) $\text{Isosynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{\text{P} + 1}\right)$ (53) For P = 0, $\text{Asynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{32}\right)$ (54) $\text{Isosynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{2}\right)$ (55) Table 29-25 contains comparative baud values for different P values, with VCLK = 50 MHz, for asynchronous mode.

29.7.13 SCI Data Buffers (SCIED, SCIRD, SCITD)

The SCI has three addressable registers in which transmit and receive data is stored. These three registers are available in SCI mode only.

29.7.13.1 Receiver Emulation Data Buffer (SCIED)

The SCIED register is addressed at a location different from SCIRD, but is physically the same register. Figure 29-40 and Table 29-26 illustrate this register.

Figure 29-40. Receiver Emulation Data Buffer (SCIED) (offset = 30h)

31	16
Reserved	
R-0	

15	8	7	0
Reserved		ED	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 29-26. Receiver Emulation Data Buffer (SCIED) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	ED	0-FFh	Emulator data. This bit is effective in SCI-compatible mode only. Reading SCIED[7:0] does not clear the RXRDY flag, unlike reading SCIRD. This register should be used only by an emulator that must continually read the data buffer without affecting the RXRDY flag.

29.7.13.2 Receiver Data Buffer (SCIRD)

This register provides a location for the receiver data. Figure 29-41 and Table 29-27 illustrate this register.

Figure 29-41. Receiver Data Buffer (SCIRD) (offset = 34h)

31	16
Reserved	
R-0	

15	8	7	0
Reserved		RD	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 29-27. Receiver Data Buffer (SCIRD) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	RD	0-FFh	Receiver data. This bit is effective in SCI-compatible mode only. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if SET RX INT is set. **Note: When the data is read from SCIRD, the RXRDY flag is automatically cleared.**

NOTE: When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left justified format padded with trailing zeros. Therefore, your software should perform a logical shift on the data by the correct number of positions to make it right justified.

Copyright © 2018, Texas Instruments Incorporated

29.7.13.3 Transmit Data Buffer Register (SCITD)

Data to be transmitted is written to the SCITD register. Figure 29-42 and Table 29-28 illustrate this register.

Figure 29-42. Transmit Data Buffer Register (SCITD) (offset = 38h)

31	16
Reserved	
R-0	

15	8	7	0
Reserved		TD	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 29-28. Transmit Data Buffer Register (SCITD) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	TD	0-FFh	Transmit data. This bit is effective in SCI-compatible mode only. Data to be transmitted is written to the SCITD register. The transfer of data from this register to the transmit shift register SCITXSHF sets the TXRDY flag, which indicates that SCITD is ready to be loaded with another byte of data. **Note: If SET TX INT is set, this data transfer also causes an interrupt.**

NOTE: Data written to the SCITD register that is fewer than eight bits long must be right justified, but it does not need to be padded with leading zeros.

29.7.14 SCI Pin I/O Control Register 0 (SCIPIO0)

Table 29-33. SCI Pin I/O Control Register 2 (SCIPIO2) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2	TX IN		Transmit pin in. This bit is effective in LIN or SCI mode. This bit contains the current value on the LINTX pin.
		0	The LINTX pin is at logic low (0).
		1	The LINTX pin is at logic high (1).
1	RX IN		Receive pin in. This bit is effective in LIN or SCI mode. This bit contains the current value on the LINRX pin.
		0	The LINRX pin is at logic low (0).
		1	The LINRX pin is at logic high (1).
0	Reserved	0	Writes have no effect.

Table 29-34. SCI Pin I/O Control Register 3 (SCIPIO3) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2	TX OUT		Transmit pin out. This bit is effective in LIN or SCI mode. This pin specifies the logic to be output on pin LINTX if the following conditions are met: • TX FUNC = 0 (LINTX pin is a general-purpose I/O.) • TX DIR = 1 (LINTX pin is a general-purpose output.) See Table 29-31 for an explanation of this bit's effect in combination with other bits.
		0	The output on the LINTX is at logic low (0).
		1	The output on the LINTX pin is at logic high (1). (Output voltage is V_{OH} or higher if TXPDR = 0 and output is in high impedance state if TXPDR = 1.)
1	RX OUT		Receive pin out. This bit is effective in LIN or SCI mode. This bit specifies the logic to be output on pin LINRX if the following conditions are met: • RX FUNC = 0 (LINRX pin is a general-purpose I/O.) • RX DIR = 1 (LINRX pin is a general-purpose output.) See Table 29-32 for an explanation of this bit's effect in combination with the other bits.
		0	The output on the LINRX pin is at logic low (0).
		1	The output on the LINRX pin is at logic high (1). (Output voltage is V_{OH} or higher if RXPDR = 0, and output is in high impedance state if RXPDR = 1.)
0	Reserved	0	Writes have no effect.

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2	TX SET		Transmit pin set. This bit is effective in LIN or SCI mode. This bit sets the logic to be output on pin LINTX if the following conditions are met: • TX FUNC = 0 (LINTX pin is a general-purpose I/O.) • TX DIR = 1 (LINTX pin is a general-purpose output.) See Table 29-31 for an explanation of this bit's effect in combination with other bits.
		0	*Read:* The output on LINTX is at logic low (0). *Write:* No effect.
		1	*Read and write:* The output on LINTX is at logic high (1).
1	RX SET		Receive pin set. This bit is effective in LIN or SCI mode. This bit sets the data to be output on pin LINRX if the following conditions are met: • RX FUNC = 0 (LINRX pin is a general-purpose I/O.) • RX DIR = 1 (LINRX pin is a general-purpose output.) See Table 29-32 for an explanation of this bit's effect in combination with the other bits.
		0	*Read:* The output on LINRX is at logic low (0). *Write:* No effect.
		1	*Read and write:* The output on LINRX is at logic high (1).
0	Reserved	0	Reads return 0. Writes have no effect.

R-0							R/WP-0		R-0				R/WP-0		

LEGEND: R/W = Read/Write; R = Read only; R/WP = Read/Write in privileged mode only; *-n* = value after reset

Table 29-40. LIN Compare Register (LINCOMPARE) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reads return 0. Writes have no effect.
18-16	SDEL		2-bit synch delimiter compare. These bits are effective in LIN mode only. These bits are used to configure the number of T_{bit} for the synch delimiter in the synch field. The default value is 0. The formula to program the value (in T_{bits}) for the synchronization delimiter is: $T_{SDEL} = (SDEL + 1)\ T_{bit}$
		0	The synch delimiter has 1 T_{bit}.
		1h	The synch delimiter has 2 T_{bit}.
		2h	The synch delimiter has 3 T_{bit}.
		3h	The synch delimiter has 4 T_{bit}.
15-3	Reserved	0	Reads return 0. Writes have no effect.
2-0	SBREAK		Synch break extend. These bits are effective in LIN mode only. These bits are used to configure the number of T_{bit} for the synch break to extend the minimum 13 T_{bit} break field to a maximum of 20 T_{bit} long. Note: The default value is 0, which adds nothing to the automatically generated SYNCH BREAK. The formula to program the value (in T_{bits}) for the SYNCH BREAK is: $T_{SYNBRK} = 13T_{bit} + (SBREAK \times T_{bit})$
		0	The synch break has no additional T_{bit}.
		1h	The synch break has 1 additional T_{bit}.
		2h	The synch break has 2 additional T_{bit}.
		3h	The synch break has 3 additional T_{bit}.
		4h	The synch break has 4 additional T_{bit}.
		5h	The synch break has 5 additional T_{bit}.
		6h	The synch break has 6 additional T_{bit}.
		7h	The synch break has 7 additional T_{bit}.

Table 29-41. LIN Receive Buffer 0 Register (LINRD0) Field Descriptions

Bit	Field	Value	Description
31-24	RD0	0-FFh	Receive buffer 0. Byte 0 of the response data byte. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy bit field according to the number of bytes received. A read of this byte clears the RXDY byte. **Note: RD<x-1> is equivalent to data byte <x> of the LIN frame.**
23-16	RD1	0-FFh	Receive buffer 1. Byte 1 of the response data byte. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received.
15-8	RD2	0-FFh	Receive buffer 2. Byte 2 of the response data byte. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received.
7-0	RD3	0-FFh	Receive buffer 3. Byte 3 of the response data byte. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received.

15	8	7	0
Reserved		TX ID MASK	
R-0		R/WL-0	

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; -*n* = value after reset

Table 29-43. LIN Mask Register (LINMASK) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reads return 0. Writes have no effect.
23-16	RX ID MASK	0-FFh	Receive ID mask. These bits are effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and comparing it to the ID-byte. A compare match of the received ID with the RX ID MASK will set the ID RX flag and trigger an ID interrupt if enabled (SET ID INT in SCISETINT). A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that bit is filtered and therefore is not used in the compare.
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	TX ID MASK	0-FFh	Transmit ID mask. These bits are effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and comparing it to the ID-byte. A compare match of the received ID with the TX ID MASK will set the ID TX flag and trigger an ID interrupt if enabled (SET ID INT in SCISETINT). A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that bit is filtered and therefore is not used for the compare.

29.7.27 LIN Identification Register (LINID)

Figure 29-56 and Table 29-44 illustrate this register.

Figure 29-56. LIN Identification Register (LINID) (offset = 70h)

31	24	23	16
Reserved		RECEIVED ID	
R-0		R-0	

15	8	7	0
ID-SlaveTask BYTE		ID BYTE	
R/WL-0		R/WL-0	

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; -*n* = value after reset

Table 29-44. LIN Identification Register (LINID) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reads return 0. Writes have no effect.
23-16	RECEIVED ID	0-FFh	Received identification. These bits are effective in LIN mode only. This byte contains the current message identifier. During header reception the received ID is copied from the SCIRXSHF register to this byte if there is no ID-parity error and there has been an RX/TX match.
15-8	ID-SLAVETASK BYTE	0-FFh	ID-SlaveTask Byte. These bits are effective in LIN mode only. This field contains the identifier to which the received ID of an incoming header will be compared to decide whether a receive response, a transmit response, or no action needs to be performed by the LIN node when a header with that particular ID is received.
7-0	ID BYTE	0-FFh	ID byte. This field is effective in LIN mode only. This byte is the LIN mode message ID. On a master node, a write to this register by the CPU initiates a header transmission. For a slave task, this byte is used for message filtering when HGEN CTRL = 0.

NOTE: For software compatibility with future LIN modules, the HGEN CTRL bit must be set to 1, the RX ID MASK field must be set to FFh, and the TX ID MASK field must be set to FFh.

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; -*n* = value after reset

Table 29-47. Maximum Baud Rate Selection Register (MBRS) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reads return 0. Writes have no effect.
12-0	MBR	0-1FFFh	Maximum baud rate prescaler. This bit is effective in LIN mode only. This 13-bit prescaler is used during the synchronization phase (see Section 29.3.1.5.2) of a slave module if the ADAPT bit is set. In this way, a SCI/LIN slave using an automatic or select bit rate modes detects any LIN bus legal rate automatically. The MBR value should be programmed to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise, a 00h data byte could mistakenly be detected as a sync break. The default value for a 70-MHz VCLK is DACh. This MBR prescaler is used by the wake-up and idle time counters for a constant expiration time relative to a 20-kHz rate. $MBR = \frac{0.9x\ VCLK}{maxbaudrate}$ (56)

Table 29-48. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions

Bit	Field	Value	Description
31	BEN		Bit error enable. This bit is effective in LIN mode only. This bit is used to create a bit error.
		0	No bit error is created.
		1	The bit received is ORed with 1 and passed to the bit monitor circuitry.
30	PBEN		Physical bus error enable. This bit is effective in LIN mode only. This bit is used to create a physical bus error.
		0	No error is created.
		1	The bit received during synch break field transmission is ORed with 1 and passed to the bit monitor circuitry.
29	CEN		Checksum error enable. This bit is effective in LIN mode only. This bit is used to create a checksum error.
		0	No error is created.
		1	The polarity of the CTYPE (checksum type) in the receive checksum calculator is changed so that a checksum error is occurred.
28	ISFE		Inconsistent synch field (ISF) error enable. This bit is effective in LIN mode only. This bit is used to create an ISF error.
		0	No error is created.
		1	The bit widths in the synch field are varied so that the ISF check fails and the error flag is set.
27	Reserved	0	Reads return 0. Writes have no effect.
26	FEN		Frame error enable. This bit is used to create a frame error.
		0	No error is created.
		1	The stop bit received is ANDed with 0 and passed to the stop bit check circuitry.

Table 29-48. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
25	PEN		Parity error enable. This bit is effective in SCI-compatible mode only. This bit is used to create a parity error.
		0	No parity error occurs.
		1	The parity bit received is toggled so that a parity error occurs.
24	BRKDT ENA		Break detect error enable. This bit is effective in SCI-compatible mode only. This bit is used to create a BRKDT error.
		0	No error is created.
		1	The stop bit of the frame is ANDed with 0 and passed to the RSM so that a frame error occurs. Then the RX pin is forced to continuous low for 10 T_{bit} so that a BRKDT error occurs.
32-21	Reserved	0	Reads return 0. Writes have no effect.
20-19	PIN SAMPLE MASK		Pin sample mask. These bits define the sample number at which the TX pin value that is being transmitted will be inverted to verify the receive pin samples majority detection circuitry. **Note: In IODFT mode testing for pin_sample mask must be done with prescalar P programmed greater than 2 (P > 2).**
		0	No mask is used.
		1h	Invert the TX Pin value at TBIT_CENTER.
		2h	Invert the TX Pin value at TBIT_CENTER + SCLK.
		3h	Invert the TX Pin value at TBIT_CENTER + 2 SCLK.
18-16	TX SHIFT		Transmit shift. These bits define the amount by which the value on TX pin is delayed so that the value on the RX pin is asynchronous. This feature is not applicable to the start bit.
		0	No delay occurs.
		1h	The value is delayed by 1 SCLK.
		2h	The value is delayed by 2 SCLK.
		3h	The value is delayed by 3 SCLK.
		4h	The value is delayed by 4 SCLK.
		5h	The value is delayed by 5 SCLK.
		6h	The value is delayed by 6 SCLK.
		7h	The value is delayed by 7 SCLK.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	IODFTENA		IODFT enable key. Write access permitted in Privilege mode only.
		Ah	IODFT is enabled.
		All other values	IODFT is disabled.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	LPB ENA		Module loopback enable. Write access permitted in Privilege mode only. **Note: In analog loopback mode the complete communication path through the I/Os can be tested, whereas in digital loopback mode the I/O buffers are excluded from this path.**
		0	Digital loopback is enabled.
		1	Analog loopback is enabled in module I/O DFT mode when IODFTENA = 1010.
0	RXP ENA		Module analog loopback through receive pin enable. Write access permitted in Privilege mode only. This bit defines whether the I/O buffers for the transmit or the receive pin are included in the communication path (in analog loopback mode).
		0	Analog loopback through the transmit pin is enabled.
		1	Analog loopback through the receive pin is enabled.

30.1 Introduction

The SCI module is a universal asynchronous receiver-transmitter that implements the standard nonreturn to zero format. The SCI can be used to communicate, for example, through an RS-232 port or over a K-line.

30.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard nonreturn to zero (NRZ) format
- Double-buffered receive and transmit functions
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous or isosynchronous communication modes with no CLK pin
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports 2^{24} different baud rates provide high accuracy baud rate selection
- Capability to use Direct Memory Access (DMA) for transmit and receive data
- Four error flags and Five status flags provide detailed information regarding SCI events
- Two external pins: SCIRX and SCITX

NOTE: SCI module does not support UART Hardware Flow Control. This feature can be implemented in Software using a General Purpose I/O pin.

30.1.2 Block Diagram

Three Major components of the SCI Module are:

- Transmitter
- Baud Clock Generator
- Receiver

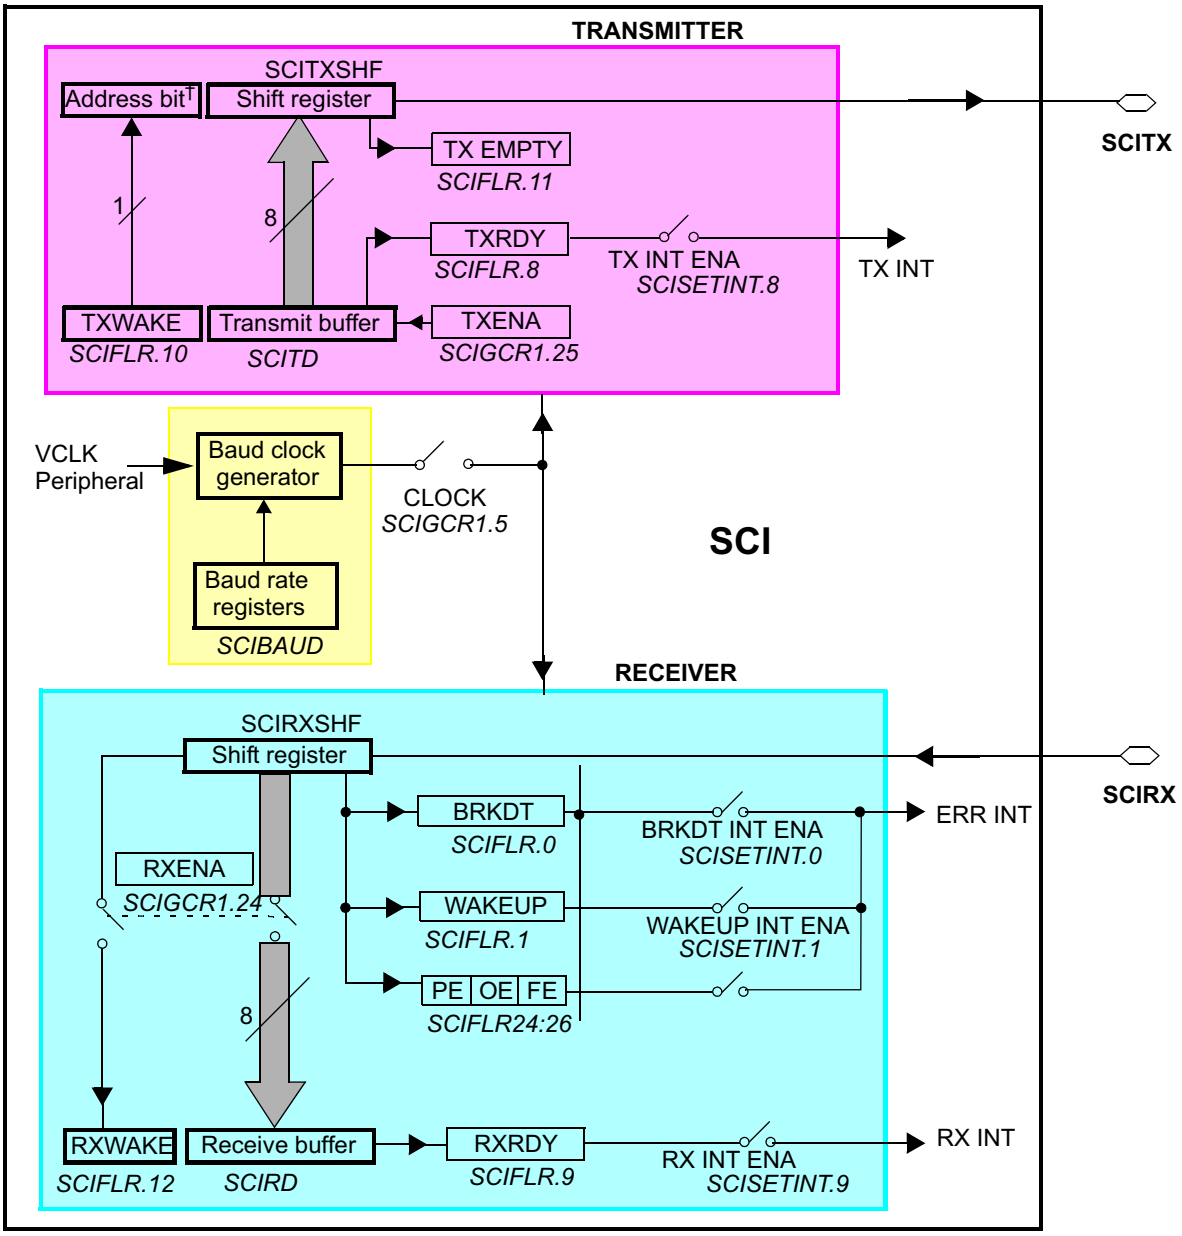
Transmitter (TX) contains two major registers to perform double buffering:

- The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
- The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the SCITX pin, one bit at a time.

Baud Clock Generator

- A programmable baud generator produces a baud clock scaled from VCLK.

Receiver (RX) contains two major registers to perform double buffering:



- The receiver shift register (SCIRXSHF) shifts data in from the SCIRX pin one bit at a time and transfers completed data into the receive data buffer.
- The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

Copyright © 2018, Texas Instruments Incorporated

The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. Figure 30-1 shows the detailed SCI block diagram.

Figure 30-1. Detailed SCI Block Diagram

30.2 SCI Communication Formats

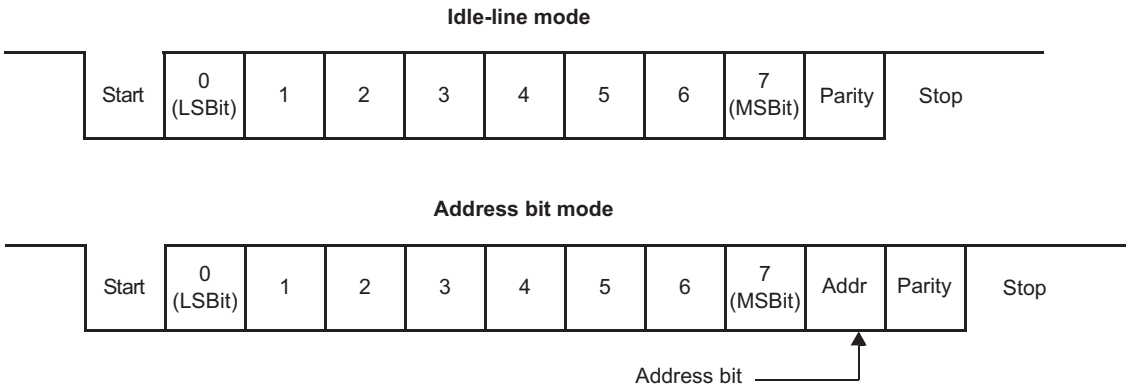
The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI are user configurable. The list below describes these configuration options:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

30.2.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits



The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in Figure 30-2.

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in Figure 30-2 have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in Figure 30-2 use one stop bit per frame.

Figure 30-2. Typical SCI Data Frame Formats

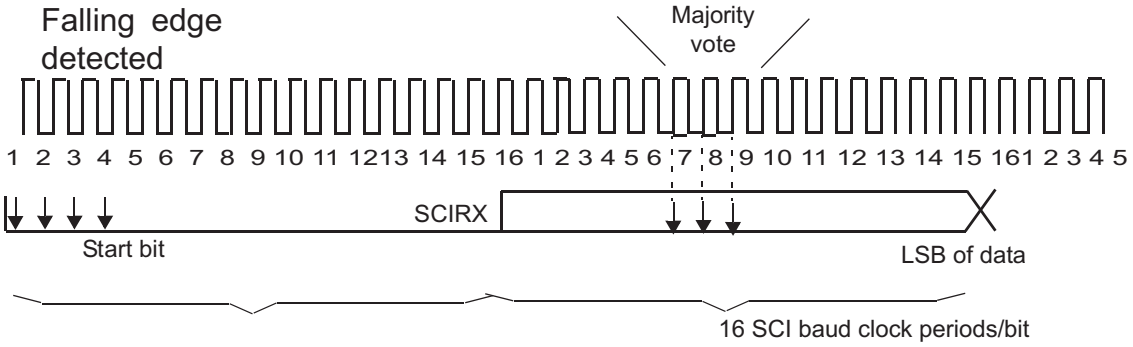
Copyright © 2018, Texas Instruments Incorporated

30.2.2 SCI Timing Mode

The SCI can be configured to use asynchronous or isosynchronous timing using TIMING MODE bit in SCIGCR1 register.

30.2.2.1 Asynchronous Timing Mode

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver- transmitter (UART) protocol.



In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the SCIRX pin are of logic level 0. As soon as a falling edge is detected on SCIRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects SCIRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the SCIRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises. Figure 30-3 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the SCITX pin. The transmitter then holds the current bit value on SCITX for 16 SCI baud clock periods.

Figure 30-3. Asynchronous Communication Bit Timing

30.2.2.2 Isosynchronous Timing Mode

In isosynchronous timing mode, each bit in a frame has a duration of exactly 1 baud clock period and therefore consists of a single sample. With this timing configuration, the transmitter and receiver are required to make use of the SCICLK pin to synchronize communication with other SCI. **This mode is not fully supported on this device because SCICLK pin is not available.**

Copyright © 2018, Texas Instruments Incorporated

30.2.3 SCI Baud Rate

The SCI has an internally generated serial clock determined by the peripheral VCLK and the prescalers BAUD. The SCI uses the 24-bit integer prescaler BAUD value in the BRS register to select the required baud rates.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\textit{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{16 * (\text{BAUD} + 1)}$$

For BAUD = 0,

$$\textit{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (57)$$

In isosynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\textit{Isosynchronous baud value} = \frac{\text{VCLK Frequency}}{\text{BAUD} + 1}$$

For BAUD = 0,

$$\textit{Isosynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (58)$$

30.2.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor Communication Modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

NOTE: Avoid Transmitting Simultaneously on the Same Serial Bus

The system designer must ensure that devices connected to the same serial bus line do not attempt to transmit simultaneously. If two devices are transmitting different data, the resulting bus conflict could damage the device..

30.2.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. Figure 30-4 illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

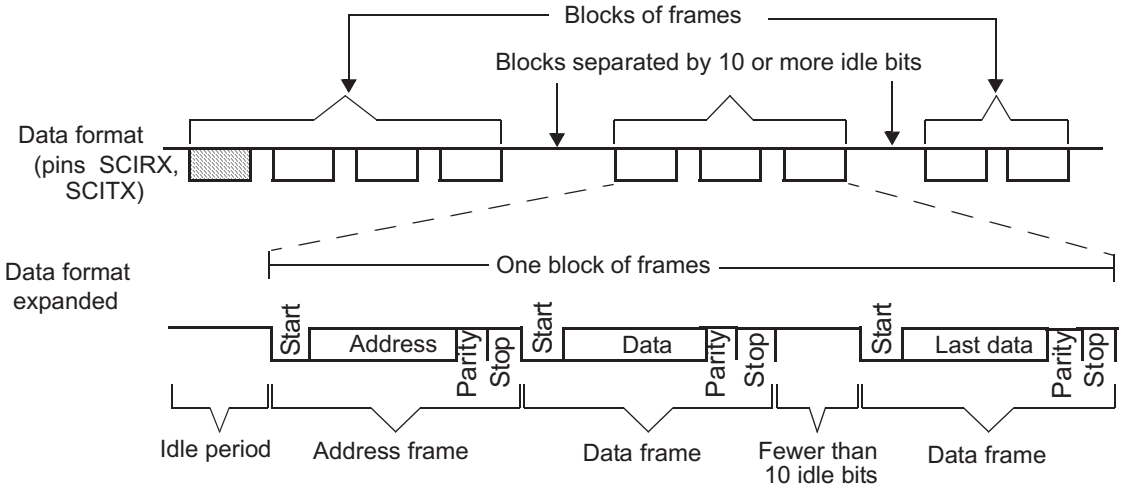
Method 1: In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

Method 2: Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step1 : Write a 1 to the TXWAKE bit.

Step2 : Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.



Step3 : Wait for the SCI to clear the TXWAKE flag.

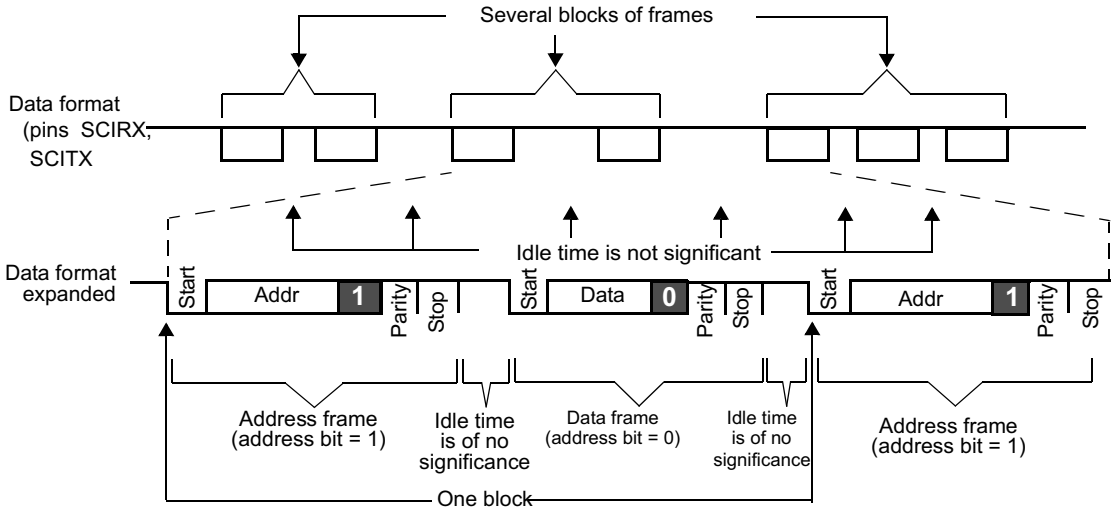
Step4 : Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

Figure 30-4. Idle-Line Multiprocessor Communication Format

Copyright © 2018, Texas Instruments Incorporated



30.2.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. Figure 30-5 illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

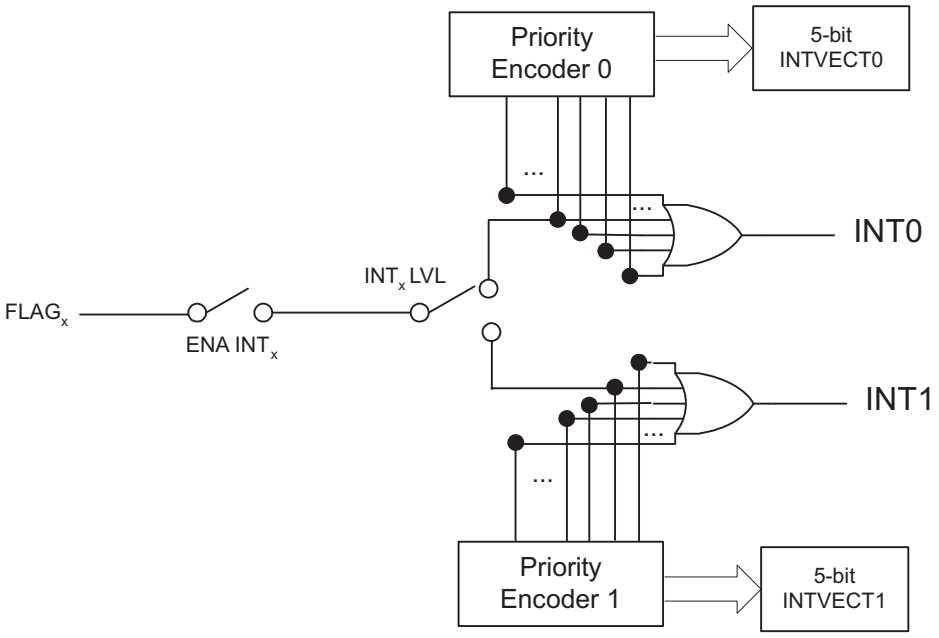
30.3 SCI Interrupts

The SCI module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see Figure 30-6). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISETINT and SCICLRINT registers, respectively.

Each interrupt also has a bit that can be set as interrupt level 0 (INT0) or as interrupt level 1 (INT1). By default, interrupts are in interrupt level 0. SCISETINTLVL sets a given interrupt to level1. SCICLEARINTLVL resets a given interrupt level to the default level 0.



The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

Figure 30-6. General Interrupt Scheme

Copyright © 2018, Texas Instruments Incorporated

Figure 30-7. Interrupt Generation for Given Flags

30.3.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled and SET TX DMA bit must be cleared. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT bit unlike transmit DMA request. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD by the User before any interrupt gets generated. To transmit further data the user can write data to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

30.3.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with both SCI and a DMA controller, the bits SET RX DMA ALL and SET RX DMA must be cleared to select interrupt functionality.

30.3.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interupt is triggered once WAKEUP flag is set.

Copyright © 2018, Texas Instruments Incorporated

30.3.4 Error Interrupts

The following error detection features are supported with Interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)

If any of these errors (PE, FE, BRKDT, OE) is flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register. Further details on these flags are explained in SCIFLR register description.

The SCI module supports following 7 interrupts as seen in Table 30-1.

Table 30-1. SCI Interrupts

Offset (1)	Interrupt
0	Reserved
1	Wakeup
2	Reserved
3	Parity error
4	Reserved
5	Reserved
6	Frame error
7	Break detect error
8	Reserved
9	Overrun error
10	Reserved
11	Receive
12	Transmit
13 - 15	Reserved

(1) Offset 1 is the highest priority. Offset 16 is the lowest priority.

Copyright © 2018, Texas Instruments Incorporated

30.4 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI module. Refer to the DMA module chapter for DMA module configurations.

30.4.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

The receiver DMA request is set when a frame is received successfully and DMA functionality has been previously enabled. The RXRDY flag is set when the SCI transfers newly received data from the SCIRXSHF register to the SCIRD buffer. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive DMA requests are enabled by the SET RX INT bit.

Parity, overrun, break detect, wake-up, and framing errors generate an error interrupt request immediately upon detection, if enabled, even if the device is in the process of a DMA data transfer. The DMA transfer is postponed until the error interrupt is served. The error interrupt can delete this particular DMA request by reading the receive buffer.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames. This is controlled by an extra select bit SET RX DMA ALL.

If the SET RX DMA ALL bit is set and the SET RX DMA bit is set when the SCI sets the RXRDY flag, then a receive DMA request is generated for address and data frames.

If the SET RX DMA ALL bit is cleared and the SET RX DMA bit is set when the SCI sets the RXRDY flag upon receipt of a data frame, then a receive DMA request is generated. Receive interrupt requests are generated for address frames.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received. Table 30-2 specifies the bit values for DMA requests in multiprocessor modes.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

Table 30-2. DMA and Interrupt Requests in Multiprocessor Modes

SET RX INT	SET RX DMA	SET RX DMA ALL	ADDR FRAME INT	ADDR FRAME DMA	DATA FRAME INT	DATA FRAME DMA
0	0	x	N	N	N	N
0	1	0	Y	N	N	Y
0	1	1	N	Y	N	Y
1	0	x	Y	N	Y	N
1	1	0	Y	N	Y	Y
1	1	1	Y	Y	Y	Y

Copyright © 2018, Texas Instruments Incorporated

30.4.2 Transmit DMA Requests

DMA functionality is enabled/disabled by the CPU with SET TX DMA/CLR TX DMA bits, respectively.

The TXRDY flag is set when the SCI transfers the contents of SCITD to SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty.

Transmit DMA requests are enabled by the setting SET TX DMA and SET TX INT bits. If the SET TX DMA bit is set, then a TX DMA request is sent to the DMA when data is written to SCITD and TXRDY is set. In other words, CPU needs to write the first data to start a DMA block transfer. For example, we want to transmit a data buffer of 20 bytes. DMA will be set up to transmit 19 bytes. The first data for DMA to transfer is the second byte in the buffer. CPU will have to write the first byte in the buffer to the SCITD register to start the transfer.

.

30.5 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the SCIRX and SCITX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bitin SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see Section 30.5.1 or Section 30.5.2).

Copyright © 2018, Texas Instruments Incorporated

30.5.1 Receiving Data

The SCI receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the SCIRX pin functions as a general-purpose I/O pin rather than as an SCI function pin. After a valid idle period is detected, data is automatically received as it arrives on the SCIRX pin.

SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from SCIRD register once RXRDY is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit is set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set.

30.5.2 Transmitting Data

The SCI transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the SCITX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit).

NOTE: The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

Copyright © 2018, Texas Instruments Incorporated

30.6 SCI Low-Power Mode

The SCI can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI. During global low-power mode, all clocks to the SCI are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the SCIRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI immediately enters low-power mode whenever it is requested and also any activity on the SCIRX pin does not cause the SCI to exit low-power mode.

NOTE: Enabling Local Low-Power Mode During Receive and Transmit

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

Copyright © 2018, Texas Instruments Incorporated

30.6.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see Table 30-11) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

30.7 SCI Control Registers

These registers are accessible in 8-, 16-, and 32-bit reads or writes. The SCI is controlled and accessed through the registers listed in Table 30-3. Among the features that can be programmed are the SCI communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration. The base address for the control registers is FFF7 E500h for SCI3 and FFF7 E700h for SCI4.

Table 30-3. SCI Control Registers Summary

Offset	Acronym	Register Description	Section
00h	SCIGCR0	SCI Global Control Register 0	Section 30.7.1

30.7.2 SCI Global Control Register 1 (SCIGCR1)

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI. Figure 30-9 and Table 30-5 illustrate this register.

Figure 30-9. SCI Global Control Register 1 (SCIGCR1) [offset = 04h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

NOTE: The SCIGCR1 Control Register Bits should not be changed during Frame Transmission or Reception.

Table 30-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reads return 0. Writes have no effect.
25	TXENA		Transmit enable. Data is transferred from SCITD to the SCITXSHF shift out register only when the TXENA bit is set.
		0	Disable transfers from SCITD to SCITXSHF.
		1	Enable SCI to transfer data from SCITD to SCITXSHF.
			Note: Data written to SCITD or the transmit multi-buffer before TXENA is set is not transmitted. If TXENA is cleared while transmission is ongoing, the data previously written to SCITD is sent.
24	RXENA		Receive enable. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD.
		0	The receiver will not transfer data from the shift buffer to the receive buffer.
		1	The receiver will transfer data from the shift buffer to the receive buffer.
			Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA.
			Note: If RXENA is cleared before a frame is completely received, the data from the frame is not transferred into the receive buffer.
			Note: If RXENA is set before a frame is completely received, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not assured to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame.
23-18	Reserved	0	Reads return 0. Writes have no effect.
17	CONT		Continue on suspend. This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI operates when the program is suspended. The
		0	When debug mode is entered, the SCI state machine is frozen. Transmissions are halted and resume when debug mode is exited.
		1	When debug mode is entered, the SCI continues to operate until the current transmit and receive functions are complete.

Copyright © 2018, Texas Instruments Incorporated

Table 30-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
16	LOOP BACK		Loopback bit. The self-checking option for the SCI can be selected with this bit. If the SCITX and SCIRX pins are configured with SCI functionality, then the SCITX pin is internally connected to the SCIRX pin. Externally, during loop back operation, the SCITX pin outputs a high value and the SCIRX pin is in a high-impedance state. If this bit value is changed while the SCI is transmitting or receiving data, errors may result.
		0	Loop back mode is disabled.
		1	Loop back mode is enabled.
15-10	Reserved	0	Reads return 0. Writes have no effect.
9	POWERDOWN		Power down. When the POWERDOWN bit is set, the SCI attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wake-up interrupt is enabled, then the SCI immediately asserts an error interrupt to prevent low-power mode from being entered. Only Privilege mode writes allowed.
		0	Normal operation.
		1	Low-power mode is enabled.
8	SLEEP		SCI sleep. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode.
		0	Sleep mode is disabled.
		1	Sleep mode is enabled.
			Note: The receiver still operates when the SLEEP bit is set; however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition.
			Note: The SLEEP bit is not automatically cleared when an address byte is detected.
			See Section 30.6.1 for more information on using the SLEEP bit for multiprocessor communication.
7	SWnRST		Software reset (active low). This bit is effective in LIN and SCI modes.
		0	The SCI is in its reset state; no data will be transmitted or received. Writing a 0 to this bit initializes the SCI state machines and operating flags as defined in Table 30-11 and Table 30-12. All affected logic is held in the reset state until a 1 is written to this bit.
		1	The SCI is in its ready state; transmission and reception can be done. After this bit is set to 1, the configuration of the module should not change.
			Note: The SCI should only be configured while SWnRST = 0.
6	Reserved	0	Reads return 0. Writes have no effect.
5	CLOCK		SCI internal clock enable. The CLOCK bit determines the source of the module clock on the SCICLK pin.
		0	The external SCICLK is the clock source.
		1	The internal SCICLK is the clock source.
			Note: If an external clock is selected, then the internal baud rate generator and baud rate registers are bypassed. The maximum frequency allowed for an externally sourced SCI clock is VCLK/16.
4	STOP		SCI number of stop bits per frame.
		0	One stop bit is used.
		1	Two stop bits are used.
			Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.

Table 30-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
3	PARITY		SCI parity odd/even selection. If the PARITY ENA bit is set, PARITY designates odd or even parity.
		0	Odd parity is used.
		1	Even parity is used.
			The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.
			For odd parity, the SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.
			For even parity, the SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.
2	PARITY ENA		Parity enable. This bit enables or disables the parity function.
		0	Parity is disabled; no parity bit is generated during transmission or is expected during reception.
		1	Parity is enabled. A parity bit is generated during transmission and is expected during reception.
1	TIMING MODE		SCI timing mode bit.
		0	Synchronous timing is used.
		1	Asynchronous timing is used.
0	COMM MODE		SCI communication mode bit.
		0	Idle-line mode is used.
		1	Address-bit mode is used.

R-0			R/W-0	R/W-0
7		2	1	0
Reserved			SET WAKEUP INT	SET BRKDT INT
R-0			R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 30-6. SCI Set Interrupt Register (SCISETINT) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26	SET FE INT		Set framing-error interrupt. Setting this bit enables the SCI module to generate an interrupt when a framing error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
25	SET OE INT		Set overrun-error interrupt. Setting this bit enables the SCI module to generate an interrupt when an overrun error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
24	SET PE INT		Set parity interrupt. Setting this bit enables the SCI module to generate an interrupt when a parity error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
23-19	Reserved	0	Reads return 0. Writes have no effect.
18	SET RX DMA ALL		Set receive DMA all. This bit determines if a separate interrupt is generated for the address frames sent in multiprocessor communications. When this bit is 0, RX interrupt requests are generated for address frames and DMA requests are generated for data frames. When this bit is 1, RX DMA requests are generated for both address and data frames.
		0	*Read:* The DMA request is disabled for address frames (the receive interrupt request is enabled for address frames). *Write:* No effect.
		1	*Read or write:* The DMA request is enabled for address and data frames
17	SET RX DMA		Set receiver DMA. To enable receiver DMA requests, this bit must be set. If it is cleared, interrupt requests are generated depending on bit SCISETINT.
		0	*Read:* The DMA request is disabled. *Write:* No effect.
		1	*Read or write:* The DMA request is enabled for address and data frames.

Copyright © 2018, Texas Instruments Incorporated

Table 30-6. SCI Set Interrupt Register (SCISETINT) Field Descriptions (continued)

Bit	Field	Value	Description
16	SET TX DMA		Set transmit DMA. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on SET TX INT bit (SCISETINT).
		0	*Read:* Transmit DMA request is disabled.
			Write: No effect.
		1	*Read or write:* Transmit DMA request is enabled.
15-10	Reserved	0	Reads return 0. Writes have no effect.
9	SET RX INT		Receiver interrupt enable. Setting this bit enables the SCI to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD.
		0	*Read:* The interrupt is disabled.
			Write: No effect.
		1	*Read or write:* The interrupt is enabled.
8	SET TX INT		Set transmitter interrupt. Setting this bit enables the SCI to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set.
		0	*Read:* The interrupt is disabled.
			Write: No effect.
		1	*Read or write:* The interrupt is enabled.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	SET WAKEUP INT		Set wakeup interrupt. Setting this bit enables the SCI to generate a wakeup interrupt and thereby exit low-power mode. If enabled, the wakeup interrupt is asserted when local low-power mode is requested while the receiver is busy or if a low level is detected on the SCIRX pin during low-power mode.
		0	*Read:* The interrupt is disabled.
			Write: No effect.
		1	*Read or write:* The interrupt is enabled.
0	SET BRKDT INT		Set breakdetect interrupt. Setting this bit enables the SCI to generate an error interrupt if a break condition is detected on the SCIRX pin.
		0	*Read:* The interrupt is disabled.
			Write: No effect.
		1	*Read or write:* The interrupt is enabled.

Bit	Field	Value	Description
25	CLR CE INT LVL		Clear overrun-error interrupt.
		0	*Read:* The interrupt level is mapped to the INT0 line. *Write:* No effect.
		1	*Read:* The interrupt level is mapped to the INT1 line. *Write:* The interrupt level is mapped to the INT0 line.
24	CLR PE INT LVL		Clear parity interrupt.
		0	*Read:* The interrupt level is mapped to the INT0 line. *Write:* No effect.
		1	*Read:* The interrupt level is mapped to the INT1 line. *Write:* The interrupt level is mapped to the INT0 line.
23-19	Reserved	0	Reads return 0. Writes have no effect.
18	CLR RX DMA ALL LVL		Clear receive DMA interrupt level.
		0	*Read:* The receive interrupt request for address frames is mapped to the INT0 line. *Write:* No effect.
		1	*Read:* The receive interrupt request for address frames is mapped to the INT1 line. *Write:* The receive interrupt request for address frames is mapped to the INT0 line.
17-10	Reserved	0	Reads return 0. Writes have no effect.
9	CLR RX INT LVL		Clear receiver interrupt.
		0	*Read:* The interrupt level is mapped to the INT0 line. *Write:* No effect.
		1	*Read:* The interrupt level is mapped to the INT1 line. *Write:* The interrupt level is mapped to the INT0 line.
8	CLR TX INT LVL		Clear transmitter interrupt.
		0	*Read:* The interrupt level is mapped to the INT0 line. *Write:* No effect.
		1	*Read:* The interrupt level is mapped to the INT1 line. *Write:* The interrupt level is mapped to the INT0 line.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	CLR WAKEUP INT LVL		Clear wakeup interrupt.
		0	*Read:* The interrupt level is mapped to the INT0 line. *Write:* No effect.
		1	*Read:* The interrupt level is mapped to the INT1 line. *Write:* The interrupt level is mapped to the INT0 line.
0	CLR BRKDT INT LVL		Clear breakdetect interrupt.
		0	*Read:* The interrupt level is mapped to the INT0 line. *Write:* No effect.
		1	*Read:* The interrupt level is mapped to the INT1 line. *Write:* The interrupt level is mapped to the INT0 line.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 30-10. SCI Flags Register (SCIFLR) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved		Reads return 0. Writes have no effect.
26	FE		Framing error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatibility mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI/LIN to generate an error interrupt if the SET FE INT bit (SCISETINT[26]). The framing error flag is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 • Reception of a new character/frame, depending on whether the module is in SCI compatible or LIN mode In multi-buffer mode the frame is defined in the SCIFORMAT register.
		0	*Read:* No framing error has been detected since the last clear. *Write:* No effect.
		1	*Read:* A framing error has been detected since the last clear. *Write:* The bit is cleared to 0.
25	OE		Overrun error flag. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit (SCISETINT[25]) is set. The OE flag is reset by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No overrun error has been detected since the last clear. *Write:* No effect.
		1	*Read:* An overrun error has been detected since the last clear. *Write:* The bit is cleared to 0.

Copyright © 2018, Texas Instruments Incorporated

Table 30-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
24	PE		Parity error flag. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. If the parity function is disabled (SCIGCR[2] = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit (SCISETINT[24]) is set. The PE bit is reset by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reception of a new character or frame, depending on whether the module is in SCI compatible or LIN mode, respectively • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No parity error has been detected since the last clear. *Write:* No effect.
		1	*Read:* A parity error has been detected since the last clear. *Write:* The bit is cleared to 0.
23-13	Reserved	0	Reads return 0. Writes have no effect.
12	RXWAKE		Receiver wakeup detect flag. The SCI sets this bit to indicate that the data currently in SCIRD is an address. RXWAKE is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Upon receipt of a data frame
		0	The data in SCIRD is not an address.
		1	The data in SCIRD is an address.
11	TX EMPTY		Transmitter empty flag. This flag indicates the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF) are empty. **Note: The RESET bit, an active SWnRST (SCIGCR1[7]), or a system reset sets this bit. This bit does not cause an interrupt request.**
		0	Transmitter buffer or shift register (or both) are loaded with data.
		1	Transmitter buffer and shift registers are both empty.
10	TXWAKE		Transmitter wakeup method select. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. **Note: TXWAKE is not cleared by the SWnRST bit.** *Address-bit mode*
		0	Frame to be transmitted will be data (address bit = 0).
		1	Frame to be transmitted will be an address (address bit = 1).
			Idle-line mode
		0	The frame to be transmitted will be data.
		1	The following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).

Copyright © 2018, Texas Instruments Incorporated

Table 30-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
9	RXRDY		Receiver ready flag. The receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU or DMA. The SCI generates a receive interrupt when RXRDY flag bit is set if the SET RX INT bit (SCISETINT[9]) is set. RXRDY is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the SCIRD register in compatibility mode • Reading the last data byte RDy of the response in LIN mode **Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.**
		0	*Read:* No new data is in SCIRD. *Write:* No effect.
		1	*Read:* New data is ready to be read from SCIRD. *Write:* The bit is cleared to 0.
8	TXRDY		Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer is ready to get another character from a CPU or DMA write. Writing data to SCITD automatically clears this bit. This bit is set after the data of the TX buffer is shifted into the SCITXSHF register. This event can trigger a transmit interrupt after data is copied to the TX shift register SCITXSHF, if the interrupt enable bit TXINT is set. **Note: 1) TXRDY is also set to 1 by setting of the RESET bit, enabling SWnRST, or by a system reset.** **2) The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.** **3) The transmit interrupt request can be eliminated until the next series of data written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit (SCIGCR1[25]).**
		0	SCITD is full.
		1	SCITD is ready to receive the next character.
7-4	Reserved	0	Reads return 0. Writes have no effect.
3	BUSY		Bus busy flag. TThis bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the SCI clears the BUSY bit. If SET WAKEUP INT bit (SCISETINT[2]) is set and power down is requested while this bit is set, the SCI automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver, but this bit can also be cleared by the following: • Setting the SWnRST bit • Setting of the RESET bit • A system reset occurring
		0	The receiver is not currently receiving a frame.
		1	The receiver is currently receiving a frame.
2	IDLE		SCI receiver in idle state. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters the idle state if one of the following events occurs: • A system reset • An SCI software reset • A power down • The RX pin is configured as a general I/O pin
		0	The idle period has been detected; the SCI is ready to receive.
		1	The idle period has not been detected; the SCI will not receive any data.

Copyright © 2018, Texas Instruments Incorporated

Table 30-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
1	WAKEUP		Wakeup flag. This bit is set by the SCI when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISETINT[2]) is set. It is cleared by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 For compatibility mode, see the SCI document for more information on low-power mode.
		0	*Read:* The module will not wake up from power-down mode. *Write:* No effect.
		1	*Read:* Wake up from power-down mode. *Write:* The bit is cleared to 0.
0	BRKDT		SCI break-detect flag. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the SCIRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the SET BRKDT INT bit (SCISETINT[0]) is set. The BRKDT bit is reset by the following: • Setting of the SWnRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No break condition has been detected since the last clear. *Write:* No effect.
		1	*Read:* A break condition has been detected. *Write:* The bit is cleared to 0.

Table 30-11. SCI Receiver Status Flags

SCI Flag	Register	Bit	Value After Reset (1)
FE	SCIFLR	26	0
OE	SCIFLR	25	0
PE	SCIFLR	24	0
RXWAKE	SCIFLR	12	0
RXRDY	SCIFLR	9	0
BRKDT	SCIFLR	0	0

(1) The flags are frozen with their reset value while SWnRST = 0.

Table 30-12. SCI Transmitter Status Flags

SCI Flag	Register	Bit	Value After Reset (1)
TX EMPTY	SCIFLR	11	1
TXRDY	SCIFLR	8	1

(1) The flags are frozen with their reset value while SWnRST = 0.

LEGEND: R = Read only; -*n* = value after reset

Table 30-13. SCI Interrupt Vector Offset 0 (SCIINTVECT0) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	INVECT0	0-Fh	Interrupt vector offset for INT0. This register indicates the offset for interrupt line INT0. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. See Table 30-1 for a list of the interrupts. **Note: The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register).**

30.7.9 SCI Interrupt Vector Offset 1 (SCIINTVECT1)

Figure 30-16 and Table 30-14 illustrate this register.

BAUD	
R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 30-16. Baud Rate Selection Register (BRS) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reads return 0. Writes have no effect.
23-0	BAUD	0-FF FFFFh	SCI 24-bit baud selection. The SCI has an internally generated serial clock determined by the VCLK and the prescalers BAUD in this register. The SCI uses the 24-bit integer prescaler BAUD value of this register to select one of over 16,700,000. The baud rate can be calculated using the following formulas: $Asynchronous\ baud\ value = \left(\frac{VCLK\ Frequency}{16(Baud + 1)}\right)$ (59) $Isosynchronous\ baud\ value = \left(\frac{VCLK\ Frequency}{Baud + 1}\right)$ (60) For BAUD = 0, $Asynchronous\ baud\ value = \left(\frac{VCLK\ Frequency}{32}\right)$ (61) $Isosynchronous\ baud\ value = \left(\frac{VCLK\ Frequency}{2}\right)$ (62) Table 30-17 contains comparative baud values for different P values, with VCLK = 50 MHz, for asynchronous mode..

Table 30-17. Comparative Baud Values for Different P Values, Asynchronous Mode [1][2]

24-Bit Register Value		Baud Selected		Percent Error
Decimal	Hex	Ideal	Actual	
26	00001A	115200	115740	0.47
53	000035	57600	57870	0.47

30.7.12 SCI Data Buffers (SCIED, SCIRD, SCITD)

The SCI has three addressable registers in which transmit and receive data is stored.

30.7.12.1 Receiver Emulation Data Buffer (SCIED)

The SCIED register is addressed at a location different from SCIRD, but is physically the same register. Figure 30-19 and Table 30-18 illustrate this register.

Figure 30-19. Receiver Emulation Data Buffer (SCIED) [offset = 30h]

31	16
Reserved	
R-0	

15	8	7	0
Reserved		ED	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 30-18. Receiver Emulation Data Buffer (SCIED) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	ED	0-FFh	Emulator data. Reading SCIED[7:0] does not clear the RXRDY flag (SCIFLR[9]), unlike reading SCIRD. This register should be used only by an emulator that must continually read the data buffer without affecting the RXRDY flag.

30.7.12.2 Receiver Data Buffer (SCIRD)

This register provides a location for the receiver data. Figure 30-20 and Table 30-19 illustrate this register.

Figure 30-20. Receiver Data Buffer (SCIRD) [offset = 34h]

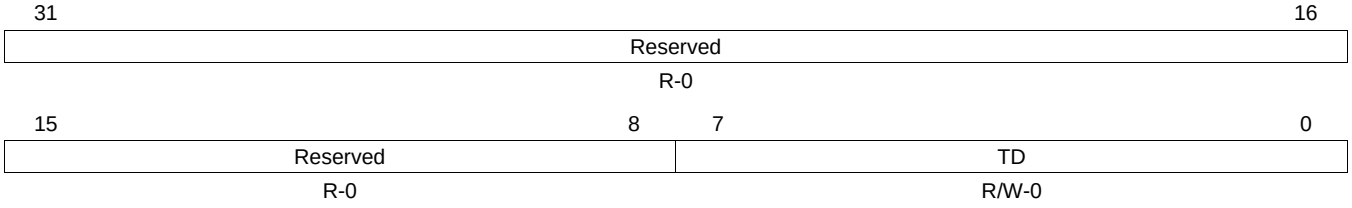
31	16
Reserved	
R-0	

15	8	7	0
Reserved		RD	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 30-19. Receiver Data Buffer (SCIRD) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	RD	0-FFh	Receiver data. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag (SCIFLR[9]) is set and a receive interrupt is generated if SET RX INT bit (SCISETINT[9]) is set. **Note: When the data is read from SCIRD, the RXRDY flag (SCIFLR[9]) is automatically cleared.**



NOTE: When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left-justified format padded with trailing zeros. Therefore, the user software should perform a logical shift on the data by the correct number of positions to make it right justified.

Copyright © 2018, Texas Instruments Incorporated

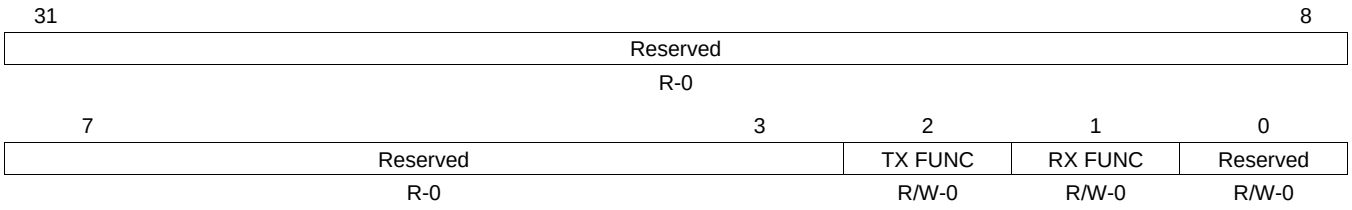
30.7.12.3 Transmit Data Buffer Register (SCITD)

Data to be transmitted is written to the SCITD register. Figure 30-21 and Table 30-20 illustrate this register.

Figure 30-21. Transmit Data Buffer Register (SCITD) [offset = 38h]

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 30-20. Transmit Data Buffer Register (SCITD) Field Descriptions



Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	TD	0-FFh	Transmit data. Data to be transmitted is written to the SCITD register. The transfer of data from this register to the transmit shift register SCITXSHF sets the TXRDY flag (SCIFLR[8]), which indicates that SCITD is ready to be loaded with another byte of data. **Note: If SET TX INT bit (SCISETINT[8] is set, this data transfer also causes an interrupt.**

NOTE: Data written to the SCITD register that is fewer than eight bits long must be right-justified, but it does not need to be padded with leading zeros.

30.7.13 SCI Pin I/O Control Register 0 (SCIPIO0)

Figure 30-22 and Table 30-21 illustrate this register.

Figure 30-22. SCI Pin I/O Control Register 0 (SCIPIO0) [offset = 3Ch]

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 30-21. SCI Pin I/O Control Register 0 (SCIPIO0) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2	TX FUNC		Transfer function. This bit defines the function of pin SCITX.
		0	SCITX is a general-purpose digital I/O pin.
		1	SCITX is the SCI transmit pin.
1	RX FUNC		Receive function. This bit defines the function of pin SCIRX.
		0	SCIRX is a general-purpose digital I/O pin.
		1	SCIRX is the SCI receive pin.
0	Reserved	0	Writes have no effect.

Table 30-26. SCI Pin I/O Control Register 3 (SCIPIO3) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2	TX OUT		Transmit pin out. This pin specifies the logic to be output on pin SCITX, if the following conditions are met: • TX FUNC = 0 (SCITX pin is a general-purpose I/O.) • TX DIR = 1 (SCITX pin is a general-purpose output.) See Table 30-23 for an explanation of this bit's effect in combination with other bits.
		0	The output on the SCITX is at logic low (0).
		1	The output on the SCITX pin is at logic high (1). (Output voltage is V_{OH} or higher if TXPDR = 0 and output is in high impedance state if TXPDR = 1.)
1	RX OUT		Receive pin out. This bit specifies the logic to be output on pin SCIRX, if the following conditions are met: • RX FUNC = 0 (SCIRX pin is a general-purpose I/O.) • RX DIR = 1 (SCIRX pin is a general-purpose output.) See Table 30-24 for an explanation of this bit's effect in combination with the other bits.
		0	The output on the SCIRX pin is at logic low (0).
		1	The output on the SCIRX pin is at logic high (1). (Output voltage is V_{OH} or higher if RXPDR = 0, and output is in high impedance state if RXPDR = 1.)
0	Reserved	0	Writes have no effect.

Table 30-32. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
18-16	TX SHIFT		Transmit shift. These bits define the amount by which the value on TX pin is delayed so that the value on the RX pin is asynchronous. This feature is not applicable to the start bit.
		0	No delay occurs.
		1h	The value is delayed by 1 SCLK.
		2h	The value is delayed by 2 SCLK.
		3h	The value is delayed by 3 SCLK.
		4h	The value is delayed by 4 SCLK.
		5h	The value is delayed by 5 SCLK.
		6h	The value is delayed by 6 SCLK.
		7h	No delay occurs.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	IODFTENA		IODFT enable key. Write access permitted in Privilege mode only.
		Ah	IODFT is enabled.
		All Others	IODFT is disabled.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	LPBENA		Module loopback enable. Write access permitted in Privilege mode only.
			Note: In analog loopback mode the complete communication path through the I/Os can be tested, whereas in digital loopback mode the I/O buffers are excluded from this path.
		0	Digital loopback is enabled.
		1	Analog loopback is enabled in module I/O DFT mode when IODFTENA = 1010.
0	RXPENA		Module analog loopback through receive pin enable. Write access permitted in Privilege mode only.
			This bit defines whether the I/O buffers for the transmit or the receive pin are included in the communication path (in analog loopback mode).
		0	Analog loopback through the transmit pin is enabled.
		1	Analog loopback through the receive pin is enabled.

30.8 GPIO Functionality

The following sections apply to all device pins that can be configured as functional or general-purpose I/O pins.

30.8.1 GPIO Functionality

Figure 30-32 illustrates the GPIO functionality.

Figure 30-32. GPIO Functionality

30.8.2 Under Reset

The following apply if a device is under reset:

- Pull control. The reset pull control on the pins is enabled.
- Input buffer. The input buffer is enabled.
- Output buffer. The output buffer is disabled.

Copyright © 2018, Texas Instruments Incorporated

30.8.3 Out of Reset

The following apply if the device is out of reset:

- Pull control. The pull control is enabled by clearing the PD (pull control disable) bit in the SCIPIO7 register (Section 30.7.20). In this case, if the PSL (pull select) bit in the SCIPIO8 register (Section 30.7.21) is set, the pin will have a pull-up. If the PSL bit is cleared, the pin will have a pull-down. If the PD bit is set in the control register, there is no pull-up or pull-down on the pin.
- Input buffer. The input buffer is always enabled in functional mode.

NOTE: The pull-disable logic depends on the pin direction. It is independent of whether the device is in I/O or functional mode. If the pin is configured as output or transmit, then the pulls are disabled automatically. If the pin is configured as input or receive, the pulls are enabled or disabled depending on bit PD in the pull disable register SCIPIO7 (Section 30.7.20).

- Output buffer. A pin can be driven as an output pin if the TX DIR bit is set in the pin direction control register (SCIPIO1; Section 30.7.14) AND the open-drain feature is not enabled in the SCIPIO6 register (Section 30.7.19).

30.8.4 Open-Drain Feature Enabled on a Pin

The following apply if the open-drain feature is enabled on a pin:

- The output buffer is enabled if a low signal is being driven on to the pin.
- The output buffer is disabled (the direction control signal DIR is internally forced low) if a high signal is being driven on to the pin.

NOTE: The open-drain feature is available only in I/O mode (SCIPIO0; Section 30.7.13).

30.8.5 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 30-33.

Table 30-33. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins

Device under Reset?	Pin Direction (DIR) [1][2]	Pull Disable (PULDIS) [1][3]	Pull Select (PULSEL) [1][4]	Pull Control	Output Buffer	Input Buffer
Yes	X	X	X	Enabled	Disabled	Enabled
No	0	0	0	Pull down	Disabled	Enabled
No	0	0	1	Pull up	Disabled	Enabled
No	0	1	0	Disabled	Disabled	Enabled
No	0	1	1	Disabled	Disabled	Enabled
No	1	X	X	Disabled	Enabled	Enabled

(1) X = Don't care
(2) DIR = 0 for input, = 1 for output
(3) PULDIS = 0 for enabling pull control
= 1 for disabling pull control
(4) PULSEL= 0 for pull-down functionality
= 1 for pull-up functionality

Inter-Integrated Circuit (I2C) Module

This chapter describes the inter-integrated circuit (I2C or I^2C) module. The I2C is a multi-master communication module providing an interface between the Texas Instruments (TI) microcontroller and devices compliant with Philips Semiconductor I^2C-bus specification version 2.1 and connected by an I2C-bus. This module will support any slave or master I2C compatible device.

Topic **Page**

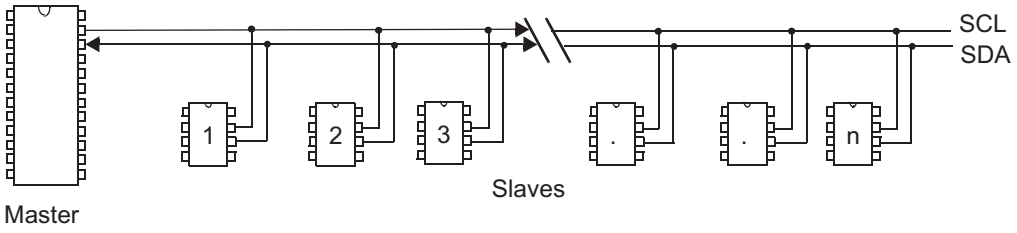
31.1 Overview **1766**
31.2 I2C Module Operation **1770**
31.3 I2C Operation Modes **1774**
31.4 I2C Module Integrity **1776**
31.5 Operational Information **1778**
31.6 I2C Control Registers **1781**
31.7 Sample Waveforms **1802**

Copyright © 2018, Texas Instruments Incorporated

31.1 Overview

The I2C has the following features:

- Compliance to the Philips I^{2}C bus specification, v2.1 (*The I2C Specification,* Philips document number 9398 393 40011)
  - Bit/Byte format transfer
  - 7-bit and 10-bit device addressing modes
  - General call
  - START byte
  - Multi-master transmitter/ slave receiver mode
  - Multi-master receiver/ slave transmitter mode
  - Combined master transmit/receive and receive/transmit mode
  - Transfer rates of 10 kbps up to 400 kbps (Phillips fast-mode rate)
- Free data format
- Two DMA events (transmit and receive)
- DMA event enable/disable capability
- Seven interrupts that can be used by the CPU
- Operates with VBUS frequency from 6.7 MHz up
- Operates with module frequency between 6.7 MHz to 13.3 MHz
- Module enable/disable capability
- The SDA and SCL are optionally configurable as general purpose I/O
- Slew rate control of the outputs
- Open drain control of the outputs
- Programmable pullup/pulldown capability on the inputs
- Supports Ignore NACK mode



NOTE: This I2C module does **not** support:

- High-speed (HS) mode
- C-bus compatibility mode
- The combined format in 10-bit address mode (the I2C sends the slave address second byte every time it sends the slave address first byte)

31.1.1 Introduction to the I2C Module

The I2C module supports any slave or master I2C-compatible device. Figure 31-1 shows an example of multiple I2C serial ports connected for a two-way transfer from one device to another device.

Figure 31-1. Multiple I2C Modules Connection Diagram

Copyright © 2018, Texas Instruments Incorporated

31.1.2 Functional Overview

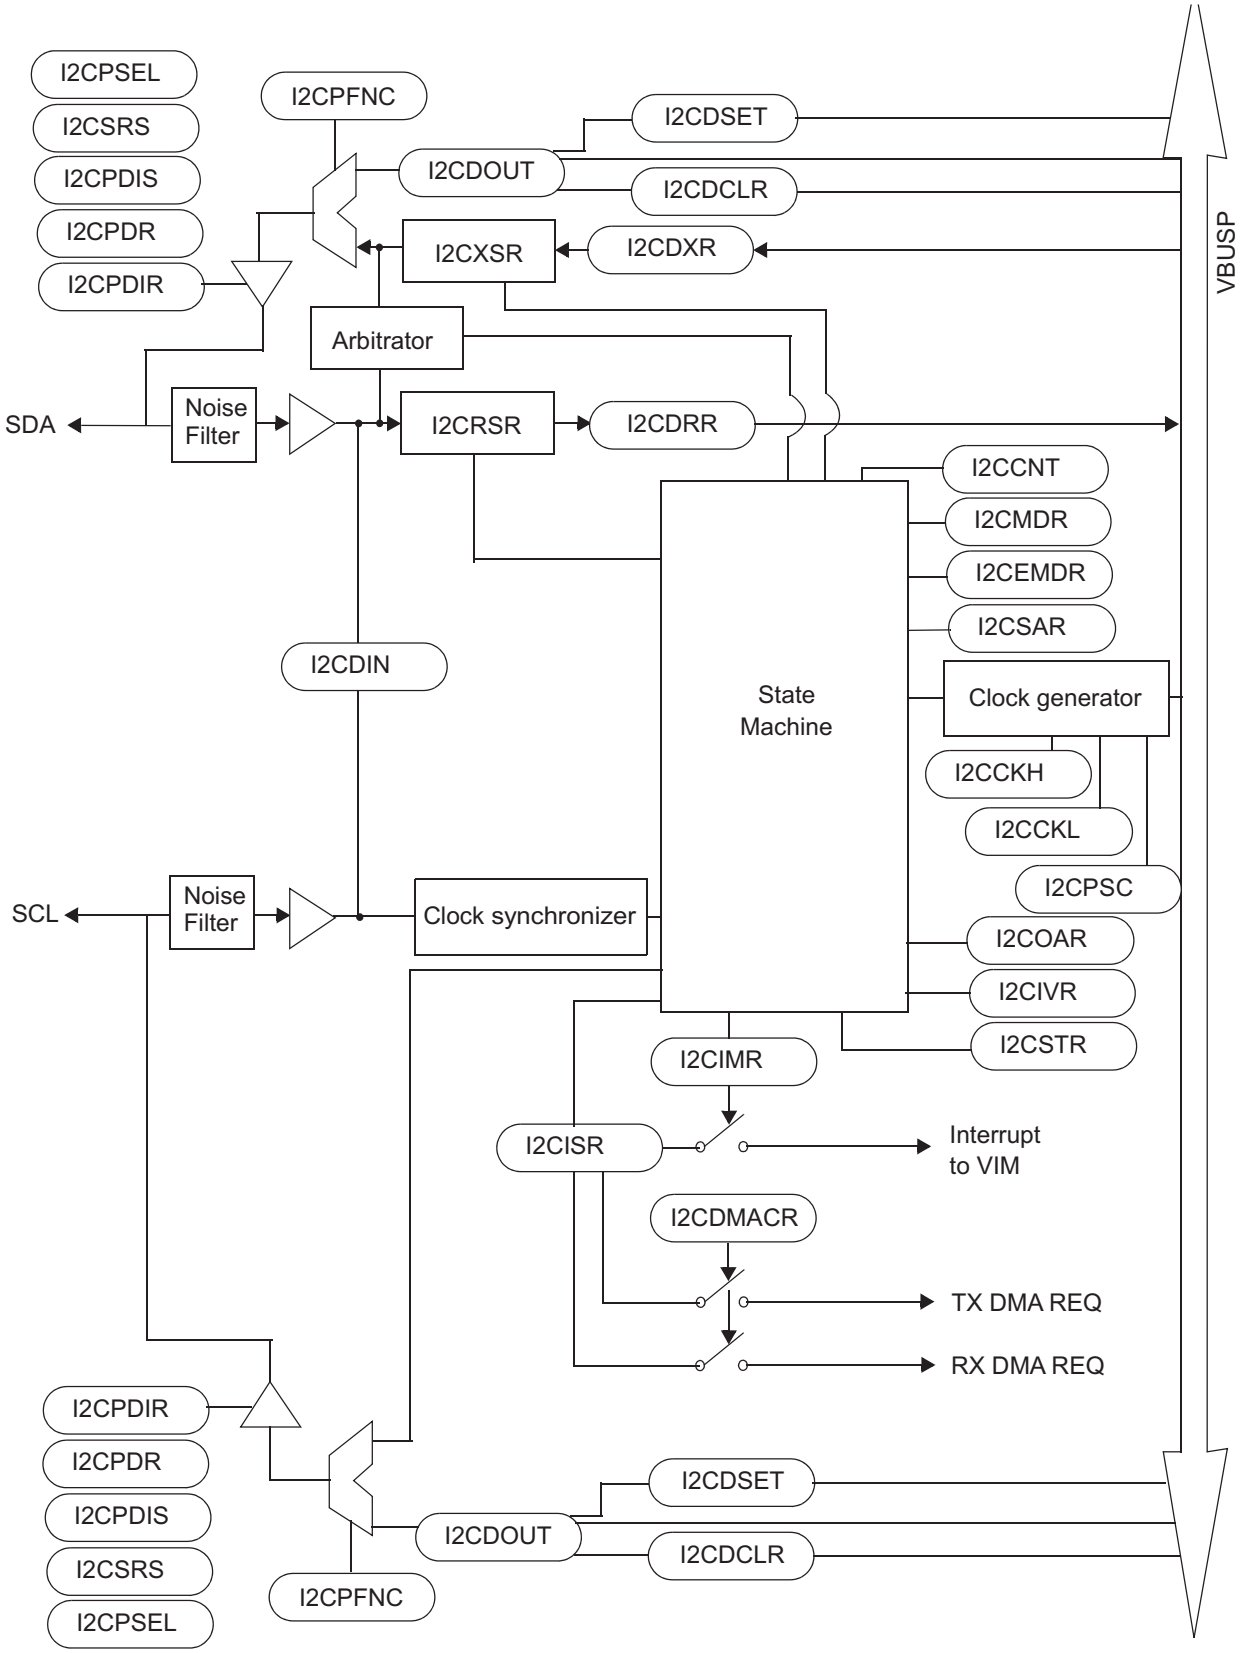
The I2C module is a serial bus that supports multiple master devices. In multimaster mode, one or more devices can be connected to the same bus and are capable of controlling the bus. Each I2C device on the bus is recognized by a unique address and can operate as either a transmitter or a receiver, depending on the function of the device. In addition to being a transmitter or receiver, a device connected to the I2C bus can also be considered a master or a slave when performing data transfers.

NOTE: A master device is the device that initiates the data transfer on a bus and generates the clock signal that permits the transfer. During the transmission, any device addressed by the master is considered the slave.

Data is communicated to devices interfacing to the I2C module using the serial data pin (SDA) and the serial clock pin (SCL) as shown in Figure 31-2. These two wires carry information between the device and the other devices connected to the I2C bus. Both SDA and SCL pins on the device are bidirectional. They must be connected to a positive supply voltage through a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the wired-AND function.

The device has a special mode that can be entered to ignore a NACK generated from non-compliant I2C devices that are incapable of generating an ACK.

The I2C module consists of the following primary blocks:



- A serial Interface: one data pin (SDA) and one clock pin (SCL)
- The device register interface
  - Data registers to temporarily hold received data and transmitted data traveling between the SDA pin and the CPU or the DMA
  - Control and status registers
- A prescaler to divide down the input clock that is driven to the I2C module
- A peripheral bus interface to enable the CPU and DMA to access the I2C module registers
- An arbitrator to handle arbitration between the I2C module (when configured as a master) and another master
- Interrupt generation logic (interrupts can be sent to the CPU)
- A clock synchronizer that synchronizes the I2C input clock (from the system module) and the clock on the SCL pin, and synchronizes data transfers with masters of different clock speeds.
- A noise filter on each of the two serial pins
- DMA event generation logic that synchronizes data reception and data transmission in the I2C module for DMA transmission

  In Figure 31-2, the CPU or the DMA writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

  When the I2C function is not needed, the pins may be controlled as general-purpose input/output (GPIO) pins. The I/O structure of each pin includes:
- programmable slew rate control of the outputs
- open drain mode
- programmable pull enable/disable on the input
- programmable pull up/pull down function on the input

31.1.3 Clock Generation

As shown in Figure 31-3, the I2C module uses the input clock generated from the device clock generator to generate the module clock and master clock. The I2C input clock is the device peripheral clock (VBUS_CLK). The clock is then divided twice more inside the I2C module to produce the module clock and the master clock.

Figure 31-3. Clocking Diagram for the I2C Module

The module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the input clock to produce the module clock. To specify the divide-down value, initialize the I2CPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$ModuleClockFrequency = \frac{I2CInputClockFrequency}{(I2CPSC + 1)} \quad (63)$$

The module clock frequency must be between 6.7MHz and 13.3MHz. The prescaler can only be initialized while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the I2CPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of the communication between the I2C module and a slave. As shown in Figure 31-3, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the I2CCKL to divide down the low portion of the module clock signal and uses the I2CCKH to divide down the high portion of the module clock signal.

The resulting frequency is:

$$MasterClockFrequency = \frac{ModuleClockFrequency}{(I2CCKL + d) + (I2CCKH + d)} \quad (64)$$

$$MasterClockFrequency = \frac{I2CInputClockFrequency}{(I2CPSC + 1)((I2CCKL + d) + (I2CCKH + d))} \quad (65)$$

where *d* depends on the value of I2CPSC:

I2CPSC	d
0	7
1	6
Greater than 1	5

Copyright © 2018, Texas Instruments Incorporated

NOTE: The master clock frequency defined above does not include rise/fall time and latency of the synchronizer inside the module. The actual transfer rate will be slower than the value calculated from the formula above. Also, due to the nature of SCL synchronization, the SCL clock period could change if SCL synchronization is taking place.

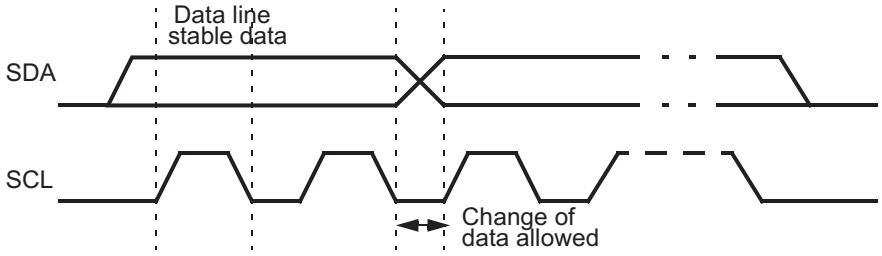
31.2 I2C Module Operation

The following section discusses how the I2C module operates.

31.2.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Because of a variety of different technology devices that can be connected to the I2C-bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of V_{CCIO}. For details, see the device specific data sheet.

31.2.2 I2C Module Reset Conditions



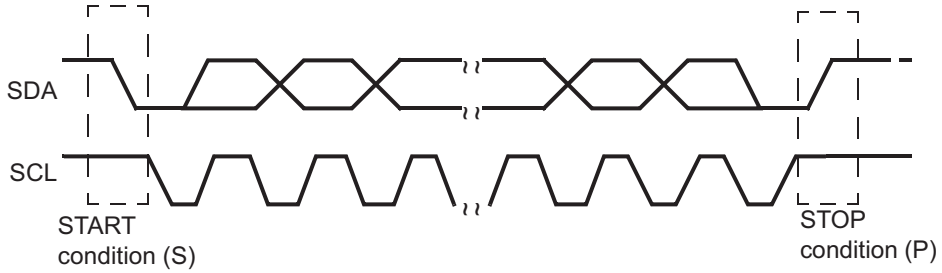
The I2C module can be reset in the following two ways:

- Through the global peripheral reset. A device reset causes a global peripheral reset.
- By clearing the $\overline{\text{IRS}}$ bit in the I2C mode register (I2CMDR). When the global peripheral reset is removed, the $\overline{\text{IRS}}$ bit is cleared to 0, keeping the I2C module in the reset state.

31.2.3 I2C Module Data Validity

The data on the SDA must be stable during the high period of the clock. See Figure 31-4. The high and low state of the data line, the SDA, can only change when the clock signal is low.

Figure 31-4. Bit Transfer on the I2C Bus



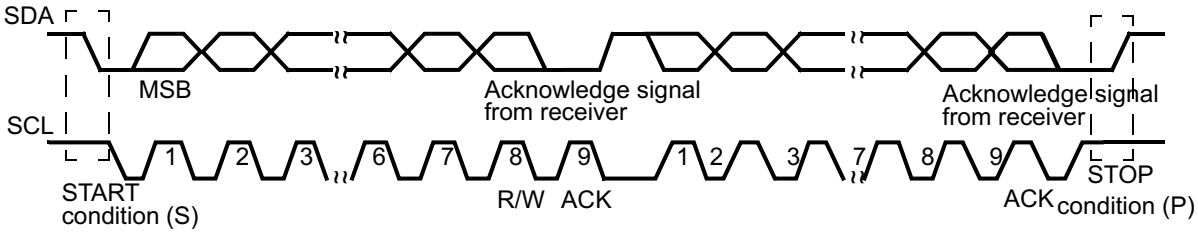
Copyright © 2018, Texas Instruments Incorporated

31.2.4 I2C Module Start and Stop Conditions

START and STOP conditions are generated by a master I2C module.

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of data transfer. The bus is considered to be busy after the START condition, and the bus busy bit (BB) in I2CSR is set to 1.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of data transfer. The bus is considered to be free after the STOP condition, therefore the BB bit in I2CSR is cleared to 0.

Figure 31-5. I2C Module START and STOP Conditions



For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in the I2CMDR must both be set to 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated.

31.2.5 Serial Data Formats

The I2C module operates in byte data format. Each message put on the SDA line is 2 to 8-bits long. The number of messages that can be transmitted or received is unrestricted. The data is transferred with the most significant bit (MSB) first (Figure 31-6). Each message is followed by an acknowledge bit from the I2C if it is in receiver mode. The I2C module does not support little endian systems.

Figure 31-6. I2C Module Data Transfer

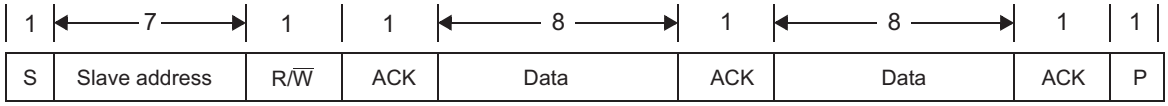
The first byte after a START condition (S) always consists of 8 bits that comprise either a 7-bit address plus the R/$\overline{W}$ bit, or 8 data bits. The eighth bit, R/W, in the first byte determines the direction of the data. When the R/$\overline{W}$ bit is 0, the master writes (transmits) data to a selected slave device; when the R/$\overline{W}$ bit is 1, the master reads (receives) data from the slave device. In acknowledge mode, an extra bit dedicated for the acknowledgement (ACK) bit is inserted after each message.

The I2C module supports the following formats:

- 7-bit addressing format (Figure 31-7)
- 10-bit addressing format (Figure 31-8)
- 7-bit/10-bit addressing format with repeated START condition (Figure 31-9)
- Free-data format (Figure 31-10)

Copyright © 2018, Texas Instruments Incorporated

31.2.5.1 7-Bit Addressing Format



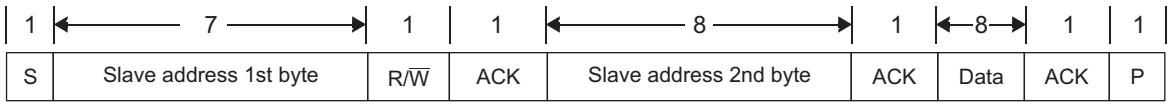
In the 7-bit addressing format (Figure 31-7), the first byte after the START condition consists of a 7-bit slave address followed by the R/$\overline{W}$ bit (in the LSB). The R/$\overline{W}$ bit determines the direction of the data transfer:

- R/$\overline{W}$ = 0: The master writes (transmits) data to the addressed slave.
- R/$\overline{W}$ = 1: The master reads (receives) data from the slave.

An extra clock cycle dedicated for acknowledgement (ACK) is inserted after each byte. If the ACK is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the R/$\overline{W}$ bit). The device I2C allows n to be a number between 2 to 8, programmable by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

To select the 7-bit addressing format, write 0 to the expanded address enable (XA) bit of I2CMDR and make sure the free data format mode is off (FDF = 0 in I2CMDR).

Figure 31-7. I2C Module 7-Bit Addressing Format



31.2.5.2 10-Bit Addressing Format

The 10-bit addressing format is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. In the 10-bit addressing format (Figure 31-8), the first byte is 11110b, the two MSBs of the 10-bit slave address, and the R/$\overline{W}$ bit. The ACK bit is inserted after each byte. The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send an acknowledgement after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use repeated a START condition to change the data direction.

To select the 10-bit addressing format, write 1 to the expanded address enable (XA) bit of I2CMDR and make sure the free data format mode is off (FDF = 0 in I2CMDR).

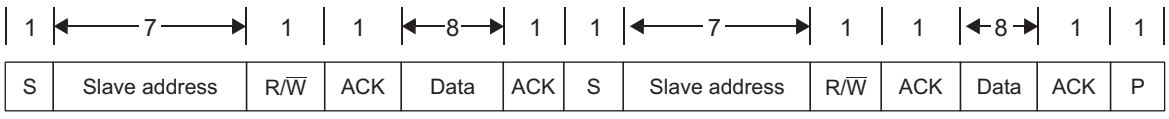


Figure 31-8. I2C Module 10-bit Addressing Format

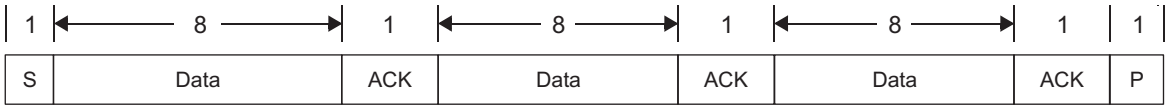
31.2.5.3 Using the Repeated START Condition

At the end of each byte, the master can drive another START condition (Figure 31-9). Using this capability, a master can transmit/receive any number of data bytes before generating a STOP condition. The length of a data byte can be from 2 to 8 bits. The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, or the free data formats.

Figure 31-9. I2C Module 7-Bit Addressing Format with Repeated START



Copyright © 2018, Texas Instruments Incorporated

31.2.5.4 Free Data Format

In this format (Figure 31-10), the first byte after a START condition is a data byte. The ACK bit is inserted after each byte, followed by another 8 bits of data. No address or data direction bit is sent. Therefore, the transmitter and receiver must both support the free data format. The direction of data transmission (transmit or receive) remains constant throughout the transfer.

To select the free data format, write a 1 to the free data format (FDF) bit of the I2CMDR. The free data format is not supported in the digital loop back mode.

Figure 31-10. I2C Module in Free Data Format

31.2.6 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 31-1 summarizes the various ways a NACK can be generated.

Table 31-1. Ways to Generate a NACK Bit

I2C Module Condition	Basic NACK Bit Generation Options	Additional Option
Slave receiver mode	Disable data transfers (STT = 0) Allow an overrun condition (RSFULL = 1) Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.
Master receiver mode and repeat mode (RM = 1)	Generate a STOP condition (STP = 1) Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.
Master receiver mode with non-repeat mode (RM = 0)	If STP = 1, allow the internal data counter to count down to 0 and thus force a STOP condition. If STP = 0, make STP = 1 to generate a STOP condition. Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.

In some applications, the slave cannot generate the ACK signal. If the IGNACK bit is set in the I2CEMDR register, the resulting NACK will be ignored and the I2C block will continue the data transfer.

31.3 I2C Operation Modes

31.3.1 Master Transmitter Mode

All masters begin in this mode. The I2C module is a master and transmits control information and data to a slave. In this mode, data assembled in any of the addressing formats shown in Figure 31-7, Figure 31-8, or Figure 31-9 is shifted out onto the SDA pin and synchronized with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL pin is held low when the intervention of the device is required ($\overline{XSMT}$ = 0) after a byte has been transmitted.

NOTE: If the I2C is configured for two simultaneous master transmissions, wait until the MST and BB have been reset before performing the second master transmission.

Failure to wait for the MST and BB to reset will prevent the start condition on the second transfer from being issued and the bus BB will not be set. Typically the end of the first transfer is handled by polling BB. However, the MST bit is not reset at the same instant as the BB bit. As a result, when the second master transmission is initiated before the resetting of the MST, the MST bit for the second transfer is reset. This prevents the I2C from recognizing itself as the master, thus failing to occupy the bus.

31.3.2 Master Receiver Mode

In this mode, the I2C module is a master and receives data from a slave. This mode can only be entered from the master transmitter mode (the I2C module must first transmit a command to the slave). In any of the addressing formats shown in Figure 31-7, Figure 31-8, or Figure 31-9, the master receiver mode is entered after the slave address byte and the R/$\overline{W}$ bit have been transmitted (if the R/$\overline{W}$ bit is 1). Serial data bits received on the SDA pin are shifted in with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL is held low when the intervention of the device is required (RSFULL = 1) after a byte has been received. At the end of the transfer, the master-receiver signals the end of data to the slave-transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave-transmitter then releases the data line allowing the master-receiver to generate a STOP condition or a repeated START condition.

In many applications, the size of the message is in the initial bytes of the message itself. Since the size of the message is not known to the master before the transmission/reception starts, the master must use the repeat mode in order to force the stop condition when the reception is completed. The repeat mode is enabled by setting the RM bit to 1. Due to the double buffer implementation on the receive side, the master must generate the stop condition (STP =1) after reading the (message size - 1)th data.

31.3.3 Slave Transmitter Mode

In this mode, the I2C module is a slave and transmits data to a master. This mode can only be entered from the slave receiver mode (The I2C module must first receive a command from the master). In any of the addressing formats shown in Figure 31-7, Figure 31-8, or Figure 31-9, the slave transmitter mode is entered if the slave address byte is the same as its own address and the R/$\overline{W}$ bit has been transmitted (if the R/$\overline{W}$ bit is set to 1). The slave transmitter shifts the serial data out on the SDA pin with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low when intervention of the device is required ($\overline{XSMT}$ = 0) after a byte has been transmitted.

31.3.4 Slave Receiver Mode

In this mode, the I2C module is a slave and receives data from a master. All slaves begin in this mode. Serial data bits received on the SDA pin are shifted in with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low while intervention of the device is required (RSFULL = 1) after a byte has been received.

Copyright © 2018, Texas Instruments Incorporated

31.3.5 Low Power Mode

The I2C module can be placed in low-power mode by a global low-power mode initiated by the system (by writing to the Peripheral Power-Down Set Register in the Peripheral Central Resource (PCR) module.

In effect, low-power mode shuts down all the clocks to the module. In global low-power mode, no registers are visible to the software; nothing can be written to or read from any register.

31.3.6 Free Run Mode

The I2C module can be placed in free run mode when the FREE bit (I2CMDR.14) is set to 1. This bit is primarily used on an emulator when encountering a breakpoint while debugging software. When the FREE bit is set to 0, the I2C responds differently depending on whether the SCL is high or low. If the SCL is low, the I2C stops immediately and keeps driving the SCL low whether the I2C is the master transmitter or receiver. If the SCL is high, the I2C waits until the SCL becomes a low and then stops. If the I2C is a slave, it stops when the transmission/reception completes.

31.3.7 Ignore NACK Mode

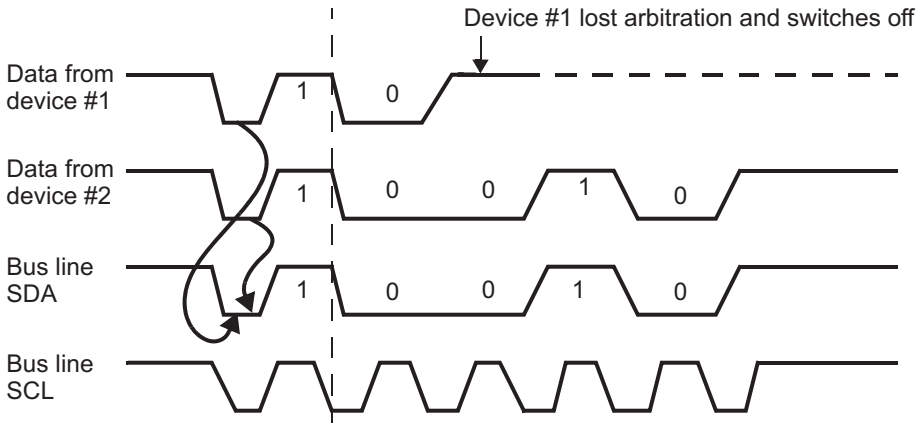
The I2C module can be placed in the ignore NACK mode by setting the IGNACK bit in the I2CEMDR register. This mode allows an I2C module that is configured as a master transmitter to ignore a NACK from a slave device that is not capable of generating a proper ACK signal.

Copyright © 2018, Texas Instruments Incorporated

31.4 I2C Module Integrity

The following section discusses how the I2C module maintains priorities and order among signals and commands.

31.4.1 Arbitration



If two or more master transmitters simultaneously start a transmission on the same bus, an arbitration procedure is invoked. Figure 31-11 illustrates the arbitration procedure between two devices. The arbitration procedure uses the data presented on the SDA bus by the competing transmitters. The first master transmitter that generates a high is overruled by the other master that generates a low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. The master transmitter that loses the arbitration switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration-lost interrupt. The data transmitted by the other master module is salvaged, and the I2C continues to receive data from the master module. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If, during a serial transfer, the arbitration procedure is still in progress when a repeated START condition or STOP condition is transmitted to I2C bus, the master transmitters involved must send the repeated START condition or STOP condition at the same position in the format frame. In other words, arbitration is not allowed between:

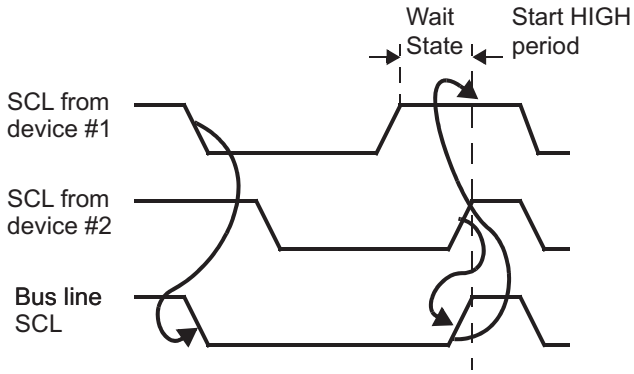
- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

Slaves are not involved in the arbitration procedure.

Figure 31-11. Arbitration Procedure Between Two Master Transmitters

Copyright © 2018, Texas Instruments Incorporated

31.4.2 I2C Clock Generation and Synchronization



Under normal conditions only one master device generates the clock signal; the SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. Figure 31-12 illustrates clock synchronization. The wired-AND property of the SCL line means that a device that first generates a low period on the SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL line is held low by the device with the longest low period. The other devices that finish their low periods must wait for the SCL line to be released before starting their high periods. A synchronized signal on the SCL is obtained where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

NOTE: I2C Protocol Fault

The following conditions violate the clock spec as defined in the Philips I²C bus specification, v2.1 (*The I2C Specification,* Philips document number 9398 393 40011), and will result in an I2C protocol fault: I2CCLKH = 2 I2CCLKL = 2I2CPSC = 2. This will cause the SDA data transition to occur while the SCL is high.

Figure 31-12. Synchronization of Two I2C Clock Generators During Arbitration

31.4.3 Prescaler

The I2C module is operated by the module clock. This clock is generated by way of the I2C prescaler block. The prescaler block consists of a 8-bit register, I2CPSC, used for dividing down the device peripheral clock (VBUS_CLK) to obtain a module clock between 6.7 MHz and 13.3 MHz.

31.4.4 Noise Filter

The noise filter is used to suppress any noises that are 50ns or less. It is designed to suppress noise with one module clock, assuming the lower and upper limits of the module clock are 6.7MHz and 13.3MHz, respectively.

Copyright © 2018, Texas Instruments Incorporated

31.5 Operational Information

The following section provides specific information about how the I2C module operates.

31.5.1 I2C Module Interrupts

The I2C module generates seven types of interrupts. These seven interrupts are accompanied with seven interrupt mask bits in the interrupt mask register (I2CIMR) and with seven interrupt flag bits in the status register (I2CSR).

31.5.1.1 I2C Interrupt Requests

The I2C module generates the interrupt requests described below. All requests are multiplexed through an arbiter into a single I2C interrupt request to the CPU. Each interrupt request has a flag bit and an enable bit. Interrupts must be enabled prior to the occurrence of the expected interrupt condition. When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the interrupt request is forwarded to the CPU as an I2C interrupt request. As an alternative, the CPU can poll all of the bits shown in Table 31-2.

Table 31-2. Interrupt Requests Generated by I2C Module

Flag	Name	Generated
AL	Arbitration-lost interrupt	Generated when the I2C module has lost an arbitration contest with another master-transmitter
NACK	No-acknowledge interrupt	Generated when the master I2C does not receive an acknowledge from the receiver
ARDY	Register-access-ready interrupt	Generated when the previously programmed address, data and command have been performed and the status bits have been updated. The interrupt is used to notify the device that the I2C registers are ready to be accessed.
RXRDY	Receive-data-ready interrupt	Generated when the received data in the receive-shift register (I2CSR) has been copied into the data receive register (I2CDRR). The RXRDY bit can also be polled by the device to determine when to read the received data in the I2CDRR.
TXRDY	Transmit-data-ready interrupt	Generated when the transmitted data has been copied from the data transmit register (I2CDXR) into the transmit-shift register (I2CXSR). The TXRDY bit can also be polled by the device to determine when to write the next data into I2CDXR.
SCD	Stop-condition-detect interrupt	Generated when a STOP condition has been detected.
AAS	Address-as-slave interrupt	Generated when the I2C has recognized its own slave address or an address of all zeroes.

The interrupt vector register (I2CIVR) contains the binary-coded-interrupt vector that indicates the highest priority interrupt that is pending and enabled. When I2CIVR is read, the corresponding interrupt flags for AL, NACK and SCD are automatically cleared, if their interrupts are enabled. Reading the I2CIVR will not clear the AAS, ARDY, RXRDY, or TXRDY interrupt pending flags. Please see Section 31.6.3 for the method to clear these four flags.

If more than one interrupt is pending, a new interrupt will be generated for the next highest priority pending interrupt when you re-enable the I2C interrupt.

A transmit interrupt is generated just after the START condition in master transmitter mode. This ensures that the CPU will get an interrupt even if no slave returns an ACK to the slave address following the START condition.

It is important to note that when the I2C is configured to generate interrupts as a slave transmitter and the backward compatibility mode (BCM) bit is set to 1, an extra transmit interrupt occurs. The application should monitor the ACK from the master to determine whether to load another byte into I2CDXR.

Copyright © 2018, Texas Instruments Incorporated

31.5.2 DMA Controller Events

The I2C module has two events that use the DMA controller to synchronously read received data (I2CREVNT) from I2CDRR, and synchronously write data (I2CWEVNT) to the transmit buffer, I2CDXR. The read and write events have the same timing as I2CRRDY (I2CRINT) and I2CXRDY (I2CXINT), respectively.

The CPU or the DMA controller reads the received data from I2CDRR and writes the data to be transmitted to I2CDXR. The RXRDY bit is automatically cleared when the DMA controller reads the I2CDRR register, and the TXRDY bit is automatically cleared when the DMA controller writes to the I2CDXR register.

Data written to I2CDXR is copied to I2CXSR and shifted out from the SDA pin when the I2C module is configured as a transmitter. When the I2C module is configured as a receiver, received data is shifted into ICRSR and copied to I2CDRR, which can be read by the CPU or the DMA controller.

A transmit event (I2CWEVNT) is generated after a START condition in master transmitter mode. This ensures that the DMA gets an event even if no slave returns an ACK to the slave address following the START condition.

NOTE: Unexpected DMA transmit and receive event

An unexpected DMA transmit event (ICXEVT) and a DMA receive event (ICXRDY) are generated in 10-bit, master transmit, repeat mode. This event occurs soon after the start condition but before the first bit of the address is transmitted. In this event, no DMA activity should be initiated without the slave ACK being received.

31.5.3 I2C Enable/Disable

The I2C module can be enabled or disabled with the I2C reset enable bit (IRS) in the I2C module register (I2CMDR). This occurs in one of two ways:

- Write 0 to the I2C reset bit (IRS) in I2CMDR. All status bits are forced to the default values and the I2C mode remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high impedance state.
- Initiate a device reset by driving the $\overline{\text{PORRST}}$ pin low. The entire device is reset and is held in the reset state until the pin is released and is driven high. When $\overline{\text{PORRST}}$ is released, all I2C module registers are reset to their default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until a 1 is written to the IRS bit.

IRS must be 0 while the I2C module is being configured. Forcing IRS to 0 can be used to save power and also clear error conditions.

31.5.4 General Purpose I/O

Both of the I2C pins can be programmed to be general-purpose I/O pins via the I2C pin control registers (I2CPFNC, I2CDIR, I2CDOUT, and I2CDIN).

When the I2C module is not used, the I2C pins may be programmed to be either general purpose input or general-purpose output pins. This function is controlled in the I2CDIR and I2CPFNC registers. Note that each pin can be programmed to be either an I2C pin or a GIO pin.

If the I2C function is to be used, the application software must ensure that each pin is configured as an I2C pin and not a GIO pin, or else unexpected behavior may result.

Copyright © 2018, Texas Instruments Incorporated

31.5.5 Pull Up/Pull Down Function

I2C module pins can have either an active pull up or active pull down that makes it possible to leave the pins unconnected externally. The pins can be programmed to have the active pull function enabled or disabled by writing to the corresponding bit in the I2CPDIS register. Please see the device-specific data sheet for the default internal pull (pull-up, pull-down or no pull) on the pins.

The pull on the pins is programmable to a setting other than the default internal pull as specified in the data sheet. The pins can be programmed to have either an active pull up or an active pull down function by writing to the corresponding bit in I2CPSEL register. The pull up/pull down function is active on the pin only when the pull enabled is programmed in the I2CPDIS register.

The pull up/pull down functions are deactivated when a bidirectional pin is configured as an output. At system reset, the pull up function of all the pins is enabled. Please see the device-specific data sheet for the current supplied by the pull up/pull down.

31.5.6 Open Drain Function

The I2C pins can be programmed to include an open drain function when they are configured as output pins. This is done by writing to the corresponding bit of the I2CPDR register. When the open drain function is enabled, a low value (0) written to the data output register forces the pin to a low output voltage (V_{OL} or lower), whereas a high value (1) written to the data output register forces the pin to a high-impedance state. The open drain function is disabled when the pin is configured as an input pin.

31.6.1 I2C Own Address Manager (I2COAR)

The 16-bit memory-mapped I2C own address register is used to specify its own address. Figure 31-13 and Table 31-4 describe this register.

Figure 31-13. I2C Own Address Manager Register (I2COAR) [offset = 00]

15	10	9	0
Reserved		OA	
R-0		R/W-0

Table 31-4. I2C Own Address Manager Register (I2COAR) Field Descriptions

Bit	Field	Value	Description
15-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	OA	0-3FFh	Own address These bits reflect the bus address of the I2C module. When the expand address (XA) bit I2CMDR.8 is set to 1, the I2C is in expand address mode (10-bit addressing mode). In either 7 or 10-bit address mode, all 10-bits are both readable and writable. Bits 7, 8, and 9 should only be used in 10-bit address mode. Table 31-5 provides the correct modes for these bits. Note that the user can program the I2C own address to any value as long as it does not conflict with other components in the system.

Table 31-5. Correct Mode for OA Bits

Bits Used	Mode	Value of XA

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 31-7. I2C Status Register (I2CSTR) Field Descriptions

Bit	Field	Value	Description
15	Reserved	0	Reads return 0. Writes have no effect.
14	SDIR		Slave direction. Setting this bit to 1 indicates that the I2C slave is a transmitter. Clearing this bit to 0 indicates that the I2C is a master transmitter/receiver or a slave receiver. This bit is also cleared by the STOP or START conditions. In DLB mode (in which the configuration should be master-transmitter slave-receiver), this bit is cleared to 0. **Writing a 1 to this bit will clear it.**
		0	The I2C is a master transmitter/receiver or a slave receiver.
		1	The I2C is a slave transmitter.
13	NACKSNT		No acknowledge sent. This bit is set to 1 to indicate that a no acknowledgement (NACK) has been sent because the NACKMOD bit was set to 1. **Writing a 1 to this bit will clear it.**
		0	A NACK has not been sent.
		1	A NACK was sent because the NACKMOD was set to 1.
12	BB		Bus busy. This bit indicates the state of the serial bus. On reception of a START condition or if the I2C detects a low state on I2CSCL, the device sets BB = 1. If the nIRS is set to 1 during transaction between other I2C devices, the BB bit is set at the first falling edge of SCL or START condition. BB is cleared to 0 after the reception of a STOP condition. BB is kept to 0 regardless of the SCL state when the I2C is in reset (nIRS = 0).
		0	The bus is free.
		1	The bus is busy.
11	RSFULL		Receiver shift full. This bit is set to 1 to indicate that the receiver has experienced overrun. Overrun occurs when the receive shift register is full and I2CDRR has not been read since the receive shift register to I2CDRR transfer. The contents of I2CDRR are not lost. The I2C core logic is holding for I2CDRR read access. This bit is also set when, in master-repeat-mode, the I2C receives a byte of data. There is no difference between RXRDY and RSFULL in this case. The I2C master will not continue the transfer as long as the received data is in the I2CDRR or receive shift register. **RSFULL is cleared when reading the I2CDRR, resetting the I2C (nIRS = 0), or resetting the device.**
		0	No overrun has occurred.
		1	An overrun has occurred.

Copyright © 2018, Texas Instruments Incorporated

Table 31-7. I2C Status Register (I2CSTR) Field Descriptions (continued)

Bit	Field	Value	Description
10	XSMT		Transmit shift empty. This bit is cleared to 0 to indicate that the transmitter has experienced underflow. Underflow occurs when the transmit shift register is empty and I2CDXR has not been loaded since the last I2CDXR to transmit shift register transfer. The I2C core logic is waiting for I2CDXR write access. **XSMT is set to 1 as a result of writing to I2CDXR, by resetting the I2C block (nIRS = 0), or by resetting the device.** In repeat mode, if the I2C in master transmitter mode is holding transfer with $\overline{\text{XSMT}}$ = 0 (that is, waiting for further action) and the STT or STP bit is set, XSMT is set to 1 by hardware.
		0	An underflow has occurred.
		1	No underflow has occurred.
9	AAS		Address as slave. **This bit cannot be cleared by writing a 1 to the bit or by reading the I2CIVR register.**
		0	This bit is cleared by a STOP condition or detection of any address byte that does not match I2COAR.
		1	This bit is set to 1 by the device when it has recognized its own slave address or an address of all zeros (general call).
8	AD0		Address zero status.
		0	A START or STOP condition was detected. No general call was detected.
		1	An address of all zeros (general call) was detected.
7-6	Reserved	0	Reads return 0. Writes have no effect.
5	SCD		Stop condition detect interrupt flag. This bit is set to 1 when the I2C receives or sends a STOP condition. **This bit is cleared to 0 by writing a 1 to this bit or reading the value 0x0006 from I2CIVR. Writing a 1 to this bit will clear the value 0x0006 from I2CIVR.**
		0	No STOP condition has been sent or received.
		1	A STOP condition has been sent or received.
4	TXRDY		Transmit data ready interrupt flag. This bit is set to 1 to indicate when data in the transmit data register, I2CDXR, has been copied into the transmit shift register. This bit can also be polled by the device to indicate when to write the next transmitted data into the I2CDXR. **Writing a 1 to this bit will set it.** **This bit is cleared to 0 and code 0x0005 in I2CIVR is cleared when the I2CDXR is written. This bit cannot be cleared by reading the I2CIVR register.**
		0	I2CDXR contains data to transmit.
		1	I2CDXR is empty.
3	RXRDY		Receive data ready interrupt flag. This bit is set to 1 to indicate when the data in the receive shift register has been copied into the data receive register (I2CDRR). This bit can also be polled by the device to indicate when to read the received data in the I2CDRR. **Writing a 1 to this bit or reading from I2CDRR will clear this bit, and will also clear code 0x0004 from I2CIVR. This bit cannot be cleared by reading the I2CIVR register.**
		0	The I2CDRR has been read.
		1	The received data has been written into the I2CDRR.

Copyright © 2018, Texas Instruments Incorporated

Table 31-7. I2C Status Register (I2CSTR) Field Descriptions (continued)

Bit	Field	Value	Description
2	ARDY		Register access ready interrupt flag. This bit is set to 1 when the previously programmed address, data and command has been performed and the status bit has been updated. The flag is used by the device to indicate that the I2C registers are ready to be accessed again. **This bit is automatically cleared by hardware when writing data to I2CDXR in transmit mode, reading data from I2CDRR in receive mode, or setting STT or STP bit. Writing a 1 to this bit will clear this bit. This bit cannot be cleared by reading the I2CIVR register.** When RM = 0, ARDY is set when I2CCNT is passed 0 if STP register bit has not been set. When RM = 1, ARDY is set at each byte end. When FDF = 0, ARDY is asserted after the ACK for the slave address. When FDF = 1, there is no slave address. Therefore, ARDY is asserted after sending the start condition.
		0	*Nonrepeat mode, (RM = 0):* I2C registers are not ready to be accessed. *Repeat mode (RM = 1):* I2C registers are not ready to be accessed.
		1	*Nonrepeat mode, (RM = 0):* ICCNT passes 0 (if STP bit has not been set). *Repeat mode (RM = 1)*: The end of each byte was transmitted from I2CDXR.
1	NACK		No acknowledgement interrupt. This bit is set to 1 when the master I2C does not receive an acknowledgement from the receiver. This bit is set only when the I2C has received a no-acknowledge in master mode. This bit is NOT set by no-acknowledgement after Start byte. In master start byte mode, the first byte (address of all zeroes) receives a NACK but does not clear the stop bit. **Writing a 1 to this bit or reading the value 0x0002 from I2CIVR will clear this bit.**
		0	An acknowledge was detected.
		1	No acknowledge was detected or the I2C is operating in the general call, even though an acknowledgement was received. This value clears the STP bit.
0	AL		Arbitration lost interrupt flag. This bit is set to 1 when arbitration has been lost. **Writing a 1 to this bit or reading the value 0x0001 from I2CIVR will clear this bit.**
		0	No loss of arbitration has been detected.
		1	The device in the master transmitter mode senses it has lost an arbitration. This occurs when two or more transmitters start a transmission almost simultaneously or when the I2C attempts to start a transfer while BB=1. When this is set to 1 due to arbitration lost, the device becomes a slave receiver and the MST, STT and STP bits in I2CMDR are cleared to 0.

31.6.4 I2C Clock Divider Low Register (I2CCKL)

The I2C clock divider low register is a 16-bit memory-mapped register used to divide the master clock down to obtain the I2C serial clock low time. Figure 31-16 and Table 31-8 describe this register.

Figure 31-16. I2C Clock Divider Low Register (I2CCKL) [offset = 0Ch]

15	0
CLKL	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 31-8. I2C Clock Divider Low Register (I2CCKL) Field Descriptions

Bit	Field	Description
15-0	CLKL	Low time clock division factor. Used to divide down the module clock to create the low-time portion of the master clock signal that will appear on the SCL pin: $LowTime = \left(\frac{I2CCLKL + d}{ModuleClockFrequency} \right)$ (66) where *d* is the value that depends on the I2CPSC (see Section 31.1.3). This register must be configured while the I2C is still in reset (nIRS = 0).

31.6.5 I2C Clock Control High Register (I2CCKH)

The I2C clock divider high register is a 16-bit memory-mapped register used to divide the master clock down to obtain the I2C serial clock high time. Figure 31-17 and Table 31-9 describe this register.

Figure 31-17. I2C Clock Control High Register (I2CCKH) [offset = 10h]

15	0
CLKH	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 31-9. I2C Clock Control High Register (I2CCKH) Field Descriptions

Bit	Field	Description
15-0	CLKH	High time clock division factor. Used to divide down the module clock to create the high-time portion of the master clock signal that will appear on the SCL pin: $HighTime = \left(\frac{I2CCLKH + d}{ModuleClockFrequency} \right)$ (67) where *d* is the value that depends on the I2CPSC (see Section 31.1.3). This register must be configured while the I2C is still in reset (nIRS = 0).

Copyright © 2018, Texas Instruments Incorporated

31.6.6 I2C Data Count Register (I2CCNT)

The I2C data count register is a 16-bit memory-mapped register used to count received or transmitted data bytes. This register is also used to generate the STOP condition that terminates the transfer after the counter reaches zero. Figure 31-18 and Table 31-10 describe this register.

Figure 31-18. I2C Data Count Register (I2CCNT) [offset = 14h]

15	0
CNT	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 31-10. I2C Data Count Register (I2CCNT) Field Descriptions

Bit	Field	Value	Description
15-0	CNT		Data counter.
			This down counter is used to generate a stop condition if a stop condition is specified (STP = 1).
			Note: ICCNT is a don't care when RM is set to 1.
		0	The data counter is 65536.
		1	The data counter is 1.

31.6.7 I2C Data Receive Register (I2CDRR)

The I2C data receive register is a 16-bit memory-mapped register used by the device to read the received data. Figure 31-19 and Table 31-11 describe this register.

Figure 31-19. I2C Data Receive Register (I2CDRR) [offset = 18h]

15	8	7	0
Reserved		DATARX	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 31-11. I2C Data Receive Register (I2CDRR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	DATARX	0-FFh	Receive data.
			A read from this register clears the RXRDY bit and clears code 4h from the I2CIVR register.

Copyright © 2018, Texas Instruments Incorporated

31.6.8 I2C Slave Address Register (I2CSAR)

The I2C slave address register is a 16-bit memory-mapped register used to specify the address of the slave device to communicate to on the I2C bus. Figure 31-20 and Table 31-12 describe this register.

Figure 31-20. I2C Slave Address Register (I2CSAR) [offset = 1Ch]

15	10	9	0
Reserved		SA	
R-0		R/W-3FFh	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 31-12. I2C Slave Address Register (I2CSAR) Field Descriptions

Bit	Field	Value	Description
15-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	SA		7- or 10-bit programmable slave address. In either mode, all 10-bits are readable and writable. Bits 7, 8, and 9 should only be used in 10-bit address mode. Table 31-13 illustrates the correct mode for each bit.

Table 31-13. Correct Mode for SA Bits

Bits Used	Mode	Value of XA
SA(6–0)	7-bit addressing	0
SA(9–0)	10-bit addressing	1

31.6.9 I2C Data Transmit Register (I2CDXR)

Figure 31-21 and Table 31-14 describe this register.

Figure 31-21. I2C Data Transmit Register (I2CDXR) [offset = 20h]

15	8	7	0
Reserved		DATATX	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 31-14. I2C Data Transmit Register (I2CDXR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	DATATX	0-FFh	Transmit data. Data written to this register will be transmitted on the I2C bus. A write to this register clears the TXRDY bit and clears code 0x05 from the I2CIVR register.

Copyright © 2018, Texas Instruments Incorporated

31.6.10 I2C Mode Register (I2CMDR)

Figure 31-22 and Table 31-15 describe this register.

Figure 31-22. I2C Mode Register (I2CMDR) [offset = 24h]

15	14	13	12	11	10	9	8
NACKMOD	FREE	STT	Reserved	STP	MST	TRX	XA

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 31-15. I2C Mode Register (I2CMDR) Field Descriptions

Bit	Field	Value	Description
15	NACKMOD		No-acknowledge (NACK) mode. This bit is used to send an acknowledge (ACK) or a no-acknowledge (NACK) to the transmitter. This bit is only applicable when the I2C is in receiver mode. In master receiver mode, when the internal data counter decrements to 0, the I2C sends a NACK. The master receiver I2C finishes a transfer when it sends a NACK. The I2C ignores ICCNT when NACKMOD is 1. The NACKMOD bit should be set before the rising edge of the last data bit if a NACK must be sent, and this bit is cleared once a NACK has been sent.
		0	The I2C sends an ACK to the transmitter during the acknowledge cycle.
		1	The I2C sends a NACK to the transmitter during the acknowledge cycle.
14	FREE		Free running bit. This bit is used to determine the state of the I2C when a breakpoint is encountered in the high level language (HLL) debugger.
		0	The I2C stops immediately if SCL is low and keeps driving SCL low if the I2C master is a transmitter/receiver. If SCL is high, I2C waits until SCL becomes low and then stops. If the I2C is a slave, it will stop when the transmission/reception completes.
		1	The I2C runs free.
13	STT		Start condition. The start condition bit works with the STP bit (master only mode). The STT and STP bits are configured to generate different transfer formats (see Table 31-16). The STT and STP bits can be used to terminate the repeat mode. This bit takes one I2C module clock cycle to set.
		0	STT is reset to 0 by the hardware after the START condition has been generated.
		1	STT is set to 1 by the device to generate a START condition. In master mode, setting STT to 1 generates a START condition.
12	Reserved	0	Reads return 0. Writes have no effect.
11	STP		Stop condition (Master mode only). This bit can be set to a 1 by the CPU to generate a stop condition. It is reset to 0 by the hardware after the stop condition has been generated. The stop condition is generated when ICCNT passes 0 when the I2C is in non-repeat mode (RM=0). In repeat mode (RM=1), the stop condition is generated if STP bit is 1. In transmitter mode, I2CTXRDY needs to be 1 (that is, you have to set STP bit unless you write data into I2CDXR).
		0	STP is reset to 0 by the hardware after the STOP condition has been generated.
		1	STP is set to 1 by the device to generate a STOP condition.
10	MST		Master/slave mode bit. This bit determines whether the module will operate in master or slave mode; see Table 31-17. This bit is cleared after generating a STOP condition. The BB bit is cleared first, and MST bit is cleared second. Before starting the next transaction in master mode, this bit must be confirmed to be cleared.
		0	The module is in the slave mode and the clock is received from the master device.
		1	The module is in the master mode and it generates the clock. This bit is cleared when the transfer has completed.

Copyright © 2018, Texas Instruments Incorporated

Table 31-15. I2C Mode Register (I2CMDR) Field Descriptions (continued)

Bit	Field	Value	Description
9	TRX		Transmit/receive bit. This bit determines the direction of data transmission of the I2C module. See Table 31-17.
		0	The module is in the receive mode and data on the SDA line is shifted into the data register I2CDRR.
		1	The module is in the transmit mode and the data in the I2CDXR is shifted out on the SDA line.
8	XA		Expand address enable bit. This bit controls the addressing mode. When XA is set to 1, the I2C does not support the combined format in master mode operations. However, the I2C will acknowledge and support the formats when configured as a slave. This bit needs to be configured even if the I2C is in slave mode.
		0	The mode is set to 7-bit addressing mode (normal address mode).
		1	The mode is set to 10-bit addressing mode (expanded address mode).
7	RM		Repeat mode enable bit (Master mode only). This bit is a 'don't care' if the module is configured in slave mode (MST = 0); see Table 31-16. Each time a byte of data is received, the user should decide whether or not to continue receiving more data. See Figure 31-23 for a diagram of this function.
		0	The mode is not in repeat mode.
		1	In repeat mode, data is continuously transmitted out of the ICDXR or received into the ICDRR until the STP bit is set to 1 regardless of ICCNT value. See Table 31-16 for module conditions.
6	DLB		Digital loop back enable bit. This bit enables the digital loopback mode of the I2C. This bit only applies in Master transmitter mode.
		0	Digital loop back mode is disabled.
		1	Digital loop back mode is enabled. In digital loop back mode, data transmitted out of the I2CDXR will be received in the I2CDRR. The address of the I2COAR is output on SDA.
5	nIRS		I2C reset enable bit. When cleared to 0, this bit will place all status registers in this module to their default state. Resetting nIRS during a data transfer can hang the I2C bus.
		0	I2C is in reset.
		1	I2C is out of reset.
4	STB		Start byte mode enable bit (Master mode only). The Start byte mode bit is set to 1 by the CPU to configure the I2C in Start byte mode. The I2C sends 00000001 regardless of the I2CSAR value. Refer to the Philips I2C specification for more details.
		0	The module is not in START byte mode.
		1	The module is in START byte mode.
3	FDF		Free data format enable bit. This bit configures the module to operate in free data format mode (see Table 31-17) in both master and slave modes. When FDF is 0, ARDY is asserted after ACK for the slave address. When FDF is 1, there is no slave address. Therefore, ARDY is asserted after sending the start condition. FDF mode is not supported in digital loop back mode.
		0	The module is not in free data format mode.
		1	The module is in free data format mode.
2-0	BC		Bit count. This bit defines the number of bits starting from the LSB (excluding the acknowledge bit) that are sent on the bus when data is written to the data transmit register. If the bits BC0, BC1, and BC2 are all 0, then the number of bits sent on the bus is 8. If the bit count bits are a non-zero value, then the number of bits sent on the bus is that value. The value 001 is reserved. When performing a transfer using the bit count of, for example, n (where n is nonzero), only the n least significant bits in the data receive register are valid and correct. The rest of the bits should be disregarded. See Table 31-18 for more information.

31.6.11 I2C Interrupt Vector Register (I2CIVR)

The I2C interrupt vector register is a 16-bit memory-mapped register used to indicate the occurrence of an interrupt. Figure 31-24 and Table 31-19 describe this register.

Figure 31-24. I2C Interrupt Vector Register (I2CIVR) [offset = 28h]

15 12	11 8	7 3	2 0
Reserved	TESTMD	Reserved	INTCODE
R-0	R/W-0	R-0	R/WC-0

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -*n* = value after reset

Table 31-19. I2C Interrupt Vector Register (I2CIVR) Field Descriptions

Bit	Field	Value	Description
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	TESTMD	0-3h	Reserved for internal testing.
7-3	Reserved	0	Reads return 0. Writes have no effect.
2-0	INTCODE	0-3h	Interrupt Code Bits. This binary coded interrupt vector indicates which interrupt has occurred. If there is more than one interrupt pending, reading I2CIVR provides the vector for the highest priority interrupt that is pending. Reading the I2CIVR will clear the corresponding flags in I2CSTR for AL, NACK and SCD as long as those interrupts are enabled. A new interrupt will be generated for each pending source. Reading I2CIVR will clear the INTCODE for AL, NACK, SCD, AAS, RXRDY and TXRDY. Reading I2CIVR **will not** clear the INTCODE for ARDY. The INTCODE for certains codes can also be cleared by either writing a 1 to the corresponding interrupt flag bits in I2CSTR, or by reading and writing to the receive or transmit registers. See Section 31.6.3 for more details. Users must read (clear) the I2CIVR before doing another start otherwise the I2CIVR could contain incorrect (old interrupt flag) value.

Table 31-20. Interrupt Codes for INTCODE Bits

Code	INTCODE(2-0)	Interrupt Occurred
00h	000	None
01h	001 (highest priority)	Arbitration lost (AL)
02h	010	No acknowledgement (NACK)
03h	011	Receive access ready (ARDY)
04h	100	Receive data ready (RXRDY)
05h	101	Transmit data ready (TXRDY)
06h	110	Stop condition detection (SCD)
07h	111 (lowest priority)	Address as slave (AAS)

31.6.12 I2C Extended Mode Register (I2CEMDR)

The I2C extended mode register is a 16-bit memory-mapped register that contains additional mode select bits. Figure 31-25 and Table 31-21 describe this register.

Figure 31-25. I2C Extended Mode Register (I2CEMDR) [offset = 2Ch]

15	2	1	0
Reserved		IGNACK	BCM
R-0		R/W-0	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 31-21. I2C Extended Mode Register (I2CEMDR) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	IGNACK		Ignore NACK mode.
		0	The master transmitter will operate normally, discontinue the data transfer, and set the ARDY and NACK status bits when a NACK signal is received from the slave.
		1	The master transmitter will ignore a NACK received from the slave.
0	BCM		Backwards compatibility mode. When set to 1, the I2C is compatible with previous versions of the I2C. This means the TXRDY interrupt is generated in slave-transmit mode when TXRDY is set and the I2C needs more data to transmit. This behavior causes an extra TXRDY interrupt to be generated because the I2C recognizes the end of transfer after generating an interrupt for the next byte of data. When BCM is 0, the TXRDY interrupt in slave-transmit mode is generated when XSMT = 1. In this case, the I2C generates an interrupt for the next byte after receiving the ACK from previous data. The setting of this bit only applies to slave transmit mode.
		0	The I2C is not in compatibility mode.
		1	The I2C is in compatibility mode.

31.6.13 I2C Prescale Register (I2CPSC)

The I2C prescaler register is a 16-bit memory-mapped register used for dividing down the VBUS_CLK to obtain a module clock frequency between 6.7 MHz and 13.3 MHz. Figure 31-26 and Table 31-22 describe this register.

Figure 31-26. I2C Prescale Register (I2CPSC) [offset = 30h]

15	8	7	0
Reserved		PSC	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 31-22. I2C Prescale Register (I2CPSC) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	PSC	0-FFh	Prescale 8-bit prescaler to divide down the VBUS clock to obtain the I2C module clock. This register must be initialized while the I2C is still in reset (nIRS = 0). The value takes effect on the rising edge of nIRS. See Section 31.1.3 for more information.

31.6.16 I2C DMA Control Register (I2CDMACR)

This register contains the transmit and receive DMA enable bits. Figure 31-29 and Table 31-25 describe this register.

Figure 31-29. I2C DMA Control Register (I2CDMACR) [offset = 3Ch]

15	2	1	0
Reserved		TXDMAEN	RXDMAEN
R-0		R/W-1	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 31-25. I2C DMA Control Register (I2CDMACR) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	TXDMAEN		Transmitter DMA enable. This bit controls the transmit DMA event pin to the system. When this bit is a 1, the DMA transmit event is enabled and the DMA can occur. When this bit is a 0, the DMA transmit event is disabled. Writing a 1 to this bit will send a TXDMA request to the DMA module, if PINFUNC is also cleared to 0.
		0	The transmit DMA is disabled.
		1	The transmit DMA is enabled.
0	RXDMAEN		Receive DMA enable. This bit controls the receive DMA event pin to the system. When this bit is 1, the DMA receive event is enabled and the DMA can occur. When this bit is a 0, the DMA receive event is disabled.
		0	The receive DMA is disabled.
		1	The receive DMA is enabled.

31.6.17 I2C Pin Function Register (I2CPFNC)

Figure 31-30 and Table 31-26 describe this register.

Figure 31-30. I2C Pin Function Register (I2CPFNC) [offset = 48h]

15	1	0
Reserved		PINFUNC
R-0		R/W-0

31.6.20 I2C Data Output Register (I2CDOUT)

This register contains the values sent to the I2C pins. Figure 31-33 and Table 31-29 describe this register.

Figure 31-33. I2C Data Output Register (I2CDOUT) [offset 0x54]

15	2	1	0
Reserved		SDAOUT	SCLOUT
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 31-29. I2C Data Output Register (I2CDOUT) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAOUT		SDA data output. This function is only active if the SDA pin is configured as an I/O pin with PINFUNC = 1. This bit contains the value sent to the SDA pin.
		0	The pin is driven low.
		1	The pin is driven high.
0	SCLOUT		SCL data output. This function is only active if the SCL pin is configured as an I/O pin with PINFUNC = 1. This bit contains the value sent to the SCL pin.
		0	The pin is driven low.
		1	The pin is driven high.

31.6.21 I2C Data Set Register (I2CDSET)

The I2CDSET register is an alias of the I2CDOUT register. Figure 31-34 and Table 31-30 describe this register.

Figure 31-34. I2C Data Set Register (I2CDSET) [offset = 58h]

31.6.25.1 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 31-35.

Table 31-35. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins

Device under Reset?	Pin Direction (DIR) (1)(2)	Pull Disable (PULDIS) (1)(3)	Pull Select (PULSEL) (1)(4)	Pull Control	Output Buffer	Input Buffer
Yes	X	X	X	Enabled	Disabled	Enabled
No	0	0	0	Pull down	Disabled	Enabled
No	0	0	1	Pull up	Disabled	Enabled
No	0	1	0	Disabled	Disabled	Enabled
No	0	1	1	Disabled	Disabled	Enabled
No	1	X	X	Disabled	Enabled	Enabled

(1) X = Don't care
(2) DIR = 0 for input, = 1 for output
(3) PULDIS = 0 for enabling pull control
= 1 for disabling pull control
(4) PULSEL= 0 for pull-down functionality
= 1 for pull-up functionality

31.6.26 I2C Pins Slew Rate Select Register (I2CSRS)

This register controls the slew rate of the signal on the I2C pins. Figure 31-39 and Table 31-36 describe this register.

Figure 31-39. I2C Pins Slew Rate Select Register (I2CSRS) [offset = 6Ch]

32.1 Introduction

This document provides a functional description of the Ethernet Media Access Controller (EMAC) and physical layer (PHY) device Management Data Input/Output (MDIO) module integrated in the microcontroller. Included are the features of the EMAC and MDIO modules, a discussion of their architecture and operation, how these modules connect to the outside world, and a description of the registers for each module.

The EMAC controls the flow of packet data from the system to the PHY. The MDIO module controls PHY configuration and status monitoring.

Both the EMAC and the MDIO modules interface to the system core through a custom interface that allows efficient data transmission and reception. This custom interface is referred to as the EMAC control module and is considered integral to the EMAC/MDIO peripheral.

32.1.1 Purpose of the Peripheral

The EMAC module is used to move data between the device and another host connected to the same network, in compliance with the Ethernet protocol.

32.1.2 Features

The EMAC/MDIO has the following features:

- Synchronous 10/100 Mbps operation.
- Standard Media Independent Interface (MII) and/or Reduced Media Independent Interface (RMII) to physical layer device (PHY).
- EMAC acts as DMA master to either internal or external device memory space.
- Eight receive channels with VLAN tag discrimination for receive quality-of-service (QOS) support.
- Eight transmit channels with round-robin or fixed priority for transmit quality-of-service (QOS) support.
- Ether-Stats and 802.3-Stats statistics gathering.
- Transmit CRC generation selectable on a per channel basis.
- Broadcast frames selection for reception on a single channel.
- Multicast frames selection for reception on a single channel.
- Promiscuous receive mode frames selection for reception on a single channel (all frames, all good frames, short frames, error frames).
- Hardware flow control.
- 8k-byte local EMAC descriptor memory that allows the peripheral to operate on descriptors without affecting the CPU. The descriptor memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention. (This memory is also known as CPPI RAM.)
- Programmable interrupt logic permits the software driver to restrict the generation of back-to-back interrupts, which allows more work to be performed in a single call to the interrupt service routine.

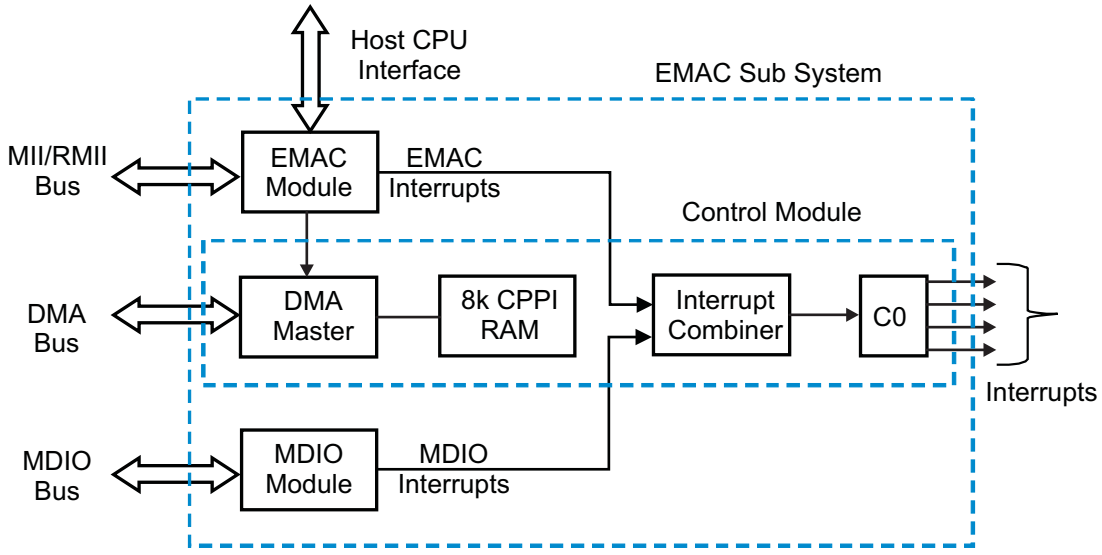
Copyright © 2018, Texas Instruments Incorporated

32.1.3 Functional Block Diagram

Figure 32-1 shows the three main functional modules of the EMAC/MDIO peripheral:

- EMAC control module
- EMAC module
- MDIO module

The EMAC control module is the main interface between the device core processor to the EMAC and MDIO modules. The EMAC control module controls device interrupts and incorporates an 8k-byte internal RAM to hold EMAC buffer descriptors (also known as CPPI RAM).



The MDIO module implements the 802.3 serial management interface to interrogate and control up to 32 Ethernet PHYs connected to the device by using a shared two-wire bus. Host software uses the MDIO module to configure the autonegotiation parameters of each PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC module for correct operation. The module is designed to allow almost transparent operation of the MDIO interface, with very little maintenance from the core processor.

The EMAC module provides an efficient interface between the processor and the network. The EMAC on this device supports 10Base-T (10 Mbits/sec) and 100BaseTX (100 Mbits/sec), half-duplex and full-duplex mode, and hardware flow control and quality-of-service (QOS) support.

Figure 32-1 shows the main interface between the EMAC control module and the CPU. The following connections are made to the device core:

- The DMA bus connection from the EMAC control module allows the EMAC module to read and write both internal and external memory through the DMA memory transfer controller.
- The EMAC control, EMAC, and MDIO modules all have control registers. These registers are memory-mapped into device memory space. Along with these registers, the control module's internal CPPI RAM is mapped into this same range.
- The EMAC and MDIO interrupts are combined into four interrupt signals within the control module. The Vectored Interrupt Manager (VIM) receives all four interrupt signals from the combiner and submits these interrupt requests to the CPU.

Figure 32-1. EMAC and MDIO Block Diagram

Copyright © 2018, Texas Instruments Incorporated

32.1.4 Industry Standard(s) Compliance Statement

The EMAC peripheral conforms to the IEEE 802.3 standard, describing the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer specifications. The IEEE 802.3 standard has also been adopted by ISO/IEC and re-designated as ISO/IEC 8802-3:2000(E).

However, the EMAC deviates from the standard in the way it handles transmit underflow errors. The EMAC MII interface does not use the Transmit Coding Error signal MTXER. Instead of driving the error pin when an underflow condition occurs on a transmitted frame, the EMAC intentionally generates an incorrect checksum by inverting the frame CRC, so that the transmitted frame is detected as an error by the network.

32.2 Architecture

This section discusses the architecture and basic function of the EMAC peripheral.

32.2.1 Clock Control

All internal EMAC logic is clocked synchronously on the VCLKA4_DIVR domain. Please refer to the *Architecture* chapter for more details.

The MDIO clock is based on a divide-down of the VCLK3 peripheral bus clock and is specified to run up to 2.5 MHz (although typical operation would be 1.0 MHz). Because the VCLK3 peripheral clock frequency is configurable, the application software or driver must control the divide-down value.

The transmit and receive clock sources are provided by the external PHY to the MII_TXCLK and MII_RXCLK pins or to the RMII reference clock pin. Data is transmitted and received with respect to the reference clocks of the interface pins.

The MII interface frequencies for the transmit and receive clocks are fixed by the IEEE 802.3 specification as:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps

The RMII interface frequency for the transmit and receive clocks are fixed at 50 MHz for both 10 Mbps and 100 Mbps.

32.2.2 Memory Map

The EMAC peripheral includes internal memory that is used to hold buffer descriptions of the Ethernet packets to be received and transmitted. This internal RAM is 2K × 32 bits in size. Data can be written to and read from the EMAC internal memory by either the EMAC or the CPU. It is used to store buffer descriptors that are 4-words (16-bytes) deep. This 8K local memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention. This EMAC RAM is also referred to as the CPPI buffer descriptor memory because it complies with the Communications Port Programming Interface (CPPI) v3.0 standard.

The packet buffer descriptors can also be placed in other on- and off-chip memories such as the CPU RAM. There are some tradeoffs in terms of interconnect bandwidth when descriptors are placed in the CPU RAM, versus when they are placed in the EMAC's internal memory. In general, the EMAC throughput is better when the descriptors are placed in the local EMAC CPPI RAM.

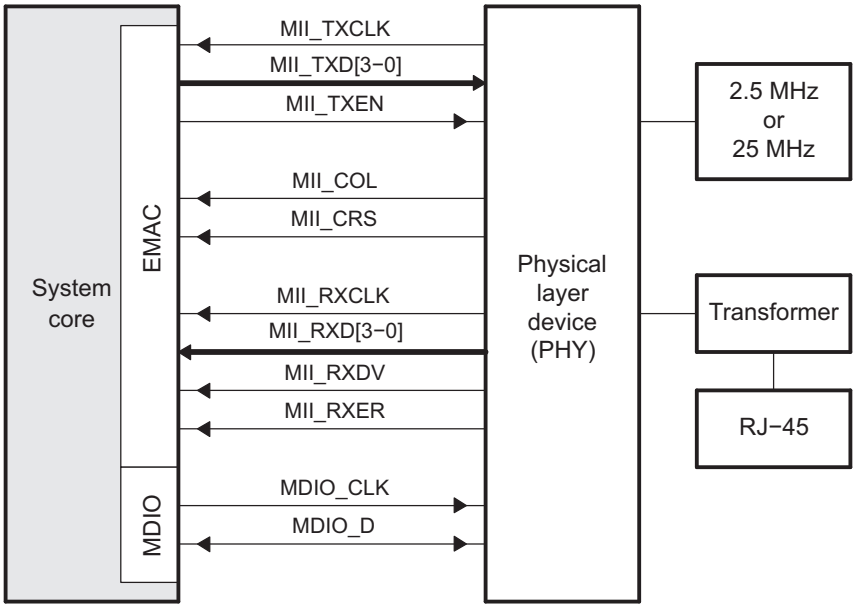
32.2.3 Signal Descriptions

The microcontrollers support both the MII and the RMII interfaces. Only one of these two interfaces can be used at a time. A separate control register in the I/O Multiplexing Module (IOMM) allows the application to indicate the actual interface being used. This is the bit 24 of the PINMMR160 control register. This bit is set by default and selects the RMII interface. The application can select the MII interface by clearing this bit. Please refer to the *I/O Multiplexing and Control Module (IOMM)* chapter for more details on the procedure to configure the PINMMR registers.



Each of the EMAC and MDIO signals for the MII and RMII interfaces are multiplexed with other I/O functions on this microcontroller. Please refer to Section 32.2.4 for information on configuration of the multiplexing control registers to enable the MII / RMII connections to these I/Os.

32.2.3.1 Media Independent Interface (MII) Connections

Figure 32-2 shows a device with integrated EMAC and MDIO interfaced via a MII connection in a typical system. The EMAC module does not include a transmit error (MTXER) pin. In the case of transmit error, CRC inversion is used to negate the validity of the transmitted frame.

The individual EMAC and MDIO signals for the MII interface are summarized in Table 32-1. For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

Figure 32-2. Ethernet Configuration—MII Connections

Copyright © 2018, Texas Instruments Incorporated

Table 32-1. EMAC and MDIO Signals for MII Interface

Signal	Type	Description
MII_TXCLK	I	Transmit clock (MII_TXCLK). The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MII_TXD and MII_TXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MII_TXD[3-0]	O	Transmit data (MII_TXD). The transmit data pins are a collection of 4 data signals comprising 4 bits of data. MTDX0 is the least-significant bit (LSB). The signals are synchronized by MII_TXCLK and valid only when MII_TXEN is asserted.
MII_TXEN	O	Transmit enable (MII_TXEN). The transmit enable signal indicates that the MII_TXD pins are generating nibble data for use by the PHY. It is driven synchronously to MII_TXCLK.
MII_COL	I	Collision detected (MII_COL). In half-duplex operation, the MII_COL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MII_TXCLK nor MII_RXCLK. In full-duplex operation, the MII_COL pin is used for hardware transmit flow control. Asserting the MII_COL pin will stop packet transmissions; packets in the process of being transmitted when MII_COL is asserted will complete transmission. The MII_COL pin should be held low if hardware transmit flow control is not used.
MII_CRS	I	Carrier sense (MII_CRS). In half-duplex operation, the MII_CRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is deasserted when both transmit and receive are idle. This signal is not necessarily synchronous to MII_TXCLK nor MII_RXCLK. In full-duplex operation, the MII_CRS pin should be held low.
MII_RXCLK	I	Receive clock (MII_RXCLK). The receive clock is a continuous clock that provides the timing reference for receive operations. The MII_RXD, MII_RXDV, and MII_RXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MII_RXD[3-0]	I	Receive data (MII_RXD). The receive data pins are a collection of 4 data signals comprising 4 bits of data. MRDX0 is the least-significant bit (LSB). The signals are synchronized by MII_RXCLK and valid only when MII_RXDV is asserted.
MII_RXDV	I	Receive data valid (MII_RXDV). The receive data valid signal indicates that the MII_RXD pins are generating nibble data for use by the EMAC. It is driven synchronously to MII_RXCLK.
MII_RXER	I	Receive error (MII_RXER). The receive error signal is asserted for one or more MII_RXCLK periods to indicate that an error was detected in the received frame. This is meaningful only during data reception when MII_RXDV is active.
MDIO_CLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL).
MDIO_D	I/O	Management data input output (MDIO_D). The MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

NOTE: The MII interface of this device is bonded out to two different sets of package pins. In one set of package pins, the interface is multiplexed with other functions on this device. The application must configure the control registers in the I/O multiplexing module in order to enable the MII functionality on the corresponding I/Os. The IO pins to which the MII interface is brought are pin compatible with other devices in the family. Please refer to Section 32.2.4 for information. This device also has a second set of package pins that brings out the MII interface. The second set of package pins for the MII interface allows the MII interface to operate in parallel with other non-MII functions in the first set of package pins. Please see the device datasheet terminal function table for detail.

32.2.3.2 Reduced Media Independent Interface (RMII) Connections

Figure 32-3 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system.

The individual EMAC and MDIO signals for the RMII interface are summarized in Table 32-2. For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

Figure 32-3. Ethernet Configuration—RMII Connections

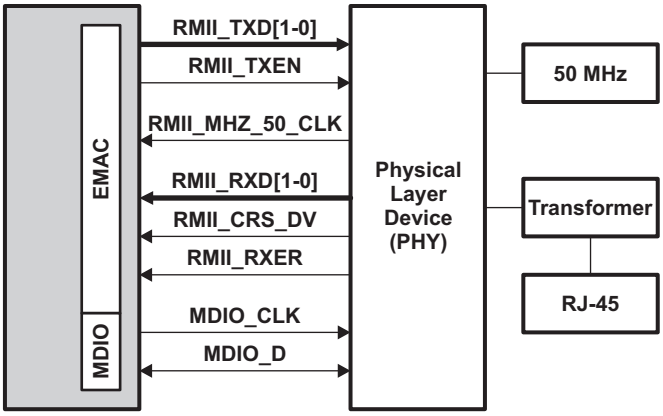

Table 32-2. EMAC and MDIO Signals for RMII Interface

Signal	Type	Description
RMII_TXD[1-0]	O	Transmit data (RMII_TXD). The transmit data pins are a collection of 2 bits of data. RMTDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_TXEN is asserted.
RMII_TXEN	O	Transmit enable (RMII_TXEN). The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK.
RMII_MHZ_50_CLK	I	RMII reference clock (RMII_MHZ_50_CLK). The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RMII_RXD[1-0]	I	Receive data (RMII_RXD). The receive data pins are a collection of 2 bits of data. RMRDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_CRS_DV is asserted and RMII_RXER is deasserted.
RMII_CRS_DV	I	Carrier sense/receive data valid (RMII_CRS_DV). Multiplexed signal between carrier sense and receive data valid.
RMII_RXER	I	Receive error (RMII_RXER). The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_CLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL).
MDIO_D	I/O	Management data input output (MDIO_D). The MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

32.2.4 MII / RMII Signal Multiplexing Control

In Each of the MII and RMII interface signals are multiplexed with other functions on this microcontroller. The application must configure the control registers in the I/O multiplexing module in order to enable the MII/RMII functionality on the corresponding I/Os. Table 32-3 shows the byte to be configured to enable the MDIO functions. Table 32-4 shows the byte to be configured to enable the MII or RMII functions. Please refer to the *I/O Multiplexing and Control Module (IOMM)* chapter for more details on the procedure to configure the PINMMR registers.

Table 32-3. MDIO Multiplexing Control

MDIO Signal Name	Control for Selecting EMAC / MDIO Signal
MDIO_CLK	PINMMR21[31:24] = 0b00000100
MDIO_D	PINMMR23 [7:0] = 0b00000100

Table 32-4. MII/RMII Multiplexing Control

MII / RMII Signal Name	Control for Selecting MII Signal	Control for Selecting RMII Signal
MII_TXCLK	PINMMR30 [23:16] = 0b00000010	-
MII_TXD[3]	PINMMR30 [7:0] = 0b00000100	-
MII_TXD[2]	PINMMR21 [15:8] = 0b00000100	-
MII_TXD[1] / RMII_TXD[1]	PINMMR26 [7:0] = 0b00000100	PINMMR26 [7:0] = 0b00001000
MII_TXD[0] / RMII_TXD[0]	PINMMR27 [7:0] = 0b00000100	PINMMR27 [7:0] = 0b00001000
MII_TXEN / RMII_TXEN	PINMMR24 [23:16] = 0b00000100	PINMMR24 [23:16] = 0b00001000

32.2.5 Ethernet Protocol Overview

A brief overview of the Ethernet protocol is given in the following subsections. See the IEEE 802.3 standard document for in-depth information on the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method.

32.2.5.1 Ethernet Frame Format

All the Ethernet technologies use the same frame structure. The format of an Ethernet frame is shown in Figure 32-4 and described in Table 32-5. The Ethernet packet, which is the collection of bytes representing the data portion of a single Ethernet frame on the wire, is shown outlined in bold. The Ethernet frames are of variable lengths, with no frame smaller than 64 bytes or larger than RXMAXLEN bytes (header, data, and CRC).

Figure 32-4. Ethernet Frame Format

Legend: SFD=Start Frame Delimeter; FCS=Frame Check Sequence (CRC)

Table 32-5. Ethernet Frame Description

Field	Bytes	Description
Preamble	7	Preamble. These 7 bytes have a fixed value of 55h and serve to wake up the receiving EMAC ports and to synchronize their clocks to that of the sender's clock.
SFD	1	Start of Frame Delimiter. This field with a value of 5Dh immediately follows the preamble pattern and indicates the start of important data.
Destination	6	Destination address. This field contains the Ethernet MAC address of the EMAC port for which the frame is intended. It may be an individual or multicast (including broadcast) address. When the destination EMAC port receives an Ethernet frame with a destination address that does not match any of its MAC physical addresses, and no promiscuous, multicast or broadcast channel is enabled, it discards the frame.
Source	6	Source address. This field contains the MAC address of the Ethernet port that transmits the frame to the Local Area Network.
Len	2	Length/Type field. The length field indicates the number of EMAC client data bytes contained in the subsequent data field of the frame. This field can also be used to identify the type of data the frame is carrying.
Data	46 to (RXMAXLEN - 18)	Data field. This field carries the datagram containing the upper layer protocol frame, that is, IP layer datagram. The maximum transfer unit (MTU) of Ethernet is (RXMAXLEN - 18) bytes. This means that if the upper layer protocol datagram exceeds (RXMAXLEN - 18) bytes, then the host has to fragment the datagram and send it in multiple Ethernet packets. The minimum size of the data field is 46 bytes. This means that if the upper layer datagram is less then 46 bytes, the data field has to be extended to 46 bytes by appending extra bits after the data field, but prior to calculating and appending the FCS.
FCS	4	Frame Check Sequence. A cyclic redundancy check (CRC) is used by the transmit and receive algorithms to generate a CRC value for the FCS field. The frame check sequence covers the 60 to 1514 bytes of the packet data. Note that this 4-byte field may or may not be included as part of the packet data, depending on how the EMAC is configured.

32.2.5.2 Ethernet's Multiple Access Protocol

Nodes in an Ethernet Local Area Network are interconnected by a broadcast channel -- when an EMAC port transmits a frame, all the adapters on the local network receive the frame. Carrier Sense Multiple Access with Collision Detection (CSMA/CD) algorithms are used when the EMAC operates in half-duplex mode. When operating in full-duplex mode, there is no contention for use of a shared medium because there are exactly two ports on the local network.

Each port runs the CSMA/CD protocol without explicit coordination with the other ports on the Ethernet network. Within a specific port, the CSMA/CD protocol works as follows:

1. The port obtains data from upper layer protocols at its node, prepares an Ethernet frame, and puts the frame in a buffer.
2. If the port senses that the medium is idle, it starts to transmit the frame. If the port senses that the transmission medium is busy, it waits until it no longer senses energy (plus an Inter-Packet Gap time) and then starts to transmit the frame.
3. While transmitting, the port monitors for the presence of signal energy coming from other ports. If the port transmits the entire frame without detecting signal energy from other Ethernet devices, the port is done with the frame.
4. If the port detects signal energy from other ports while transmitting, it stops transmitting its frame and instead transmits a 48-bit jam signal.
5. After transmitting the jam signal, the port enters an exponential backoff phase. If a data frame encounters back-to-back collisions, the port chooses a random value that is dependent on the number of collisions. The port then waits an amount of time that is a multiple of this random value and returns to step 2.

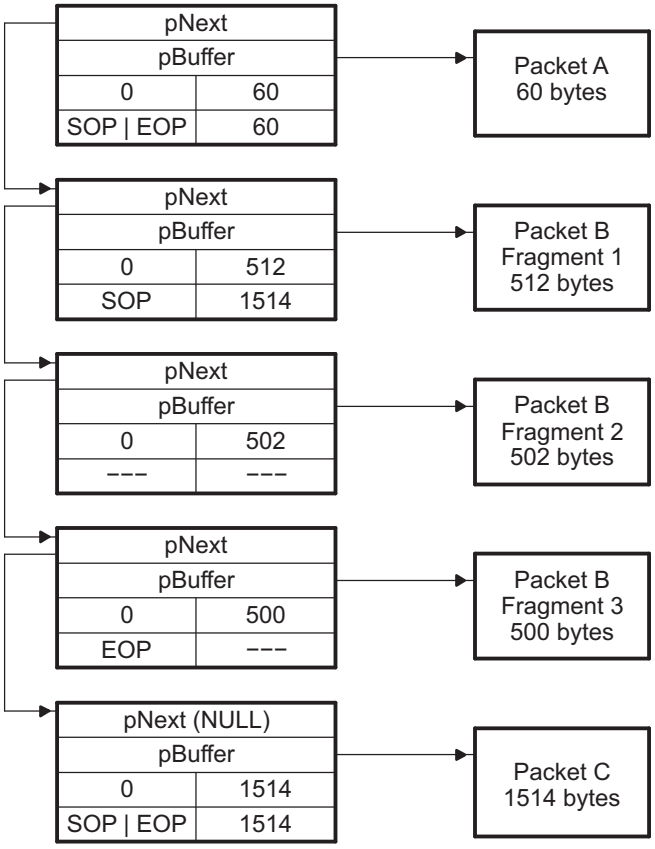
32.2.6 Programming Interface

32.2.6.1 Packet Buffer Descriptors

The buffer descriptor is a central part of the EMAC module and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data. The basic descriptor format is shown in Figure 32-5 and described in Table 32-6.

For example, consider three packets to be transmitted: Packet A is a single fragment (60 bytes), Packet B is fragmented over three buffers (1514 bytes total), and Packet C is a single fragment (1514 bytes). The linked list of descriptors to describe these three packets is shown in Figure 32-6.

Figure 32-5. Basic Descriptor Format



Word Offset	Bit Fields 31 16	15 0
0	Next Descriptor Pointer	
1	Buffer Pointer	
2	Buffer Offset	Buffer Length
3	Flags	Packet Length

Copyright © 2018, Texas Instruments Incorporated

Table 32-6. Basic Descriptor Description

Word Offset	Field	Field Description
0	Next Descriptor Pointer	The next descriptor pointer is used to create a single linked list of descriptors. Each descriptor describes a packet or a packet fragment. When a descriptor points to a single buffer packet or the first fragment of a packet, the start of packet (SOP) flag is set in the flags field. When a descriptor points to a single buffer packet or the last fragment of a packet, the end of packet (EOP) flag is set. When a packet is fragmented, each fragment must have its own descriptor and appear sequentially in the descriptor linked list.
1	Buffer Pointer	The buffer pointer refers to the actual memory buffer that contains packet data during transmit operations, or is an empty buffer ready to receive packet data during receive operations.
2	Buffer Offset	The buffer offset is the offset from the start of the packet buffer to the first byte of valid data. This field only has meaning when the buffer descriptor points to a buffer that actually contains data.
	Buffer Length	The buffer length is the actual number of valid packet data bytes stored in the buffer. If the buffer is empty and waiting to receive data, this field represents the size of the empty buffer.
3	Flags	The flags field contains more information about the buffer, such as, is it the first fragment in a packet (SOP), the last fragment in a packet (EOP), or contains an entire contiguous Ethernet packet (both SOP and EOP). The flags are described in Section 32.2.6.4 and Section 32.2.6.5.
	Packet Length	The packet length only has meaning for buffers that both contain data and are the start of a new packet (SOP). In the case of SOP descriptors, the packet length field contains the length of the entire Ethernet packet, regardless if it is contained in a single buffer or fragmented over several buffers.

32.2.6.2 Transmit and Receive Descriptor Queues

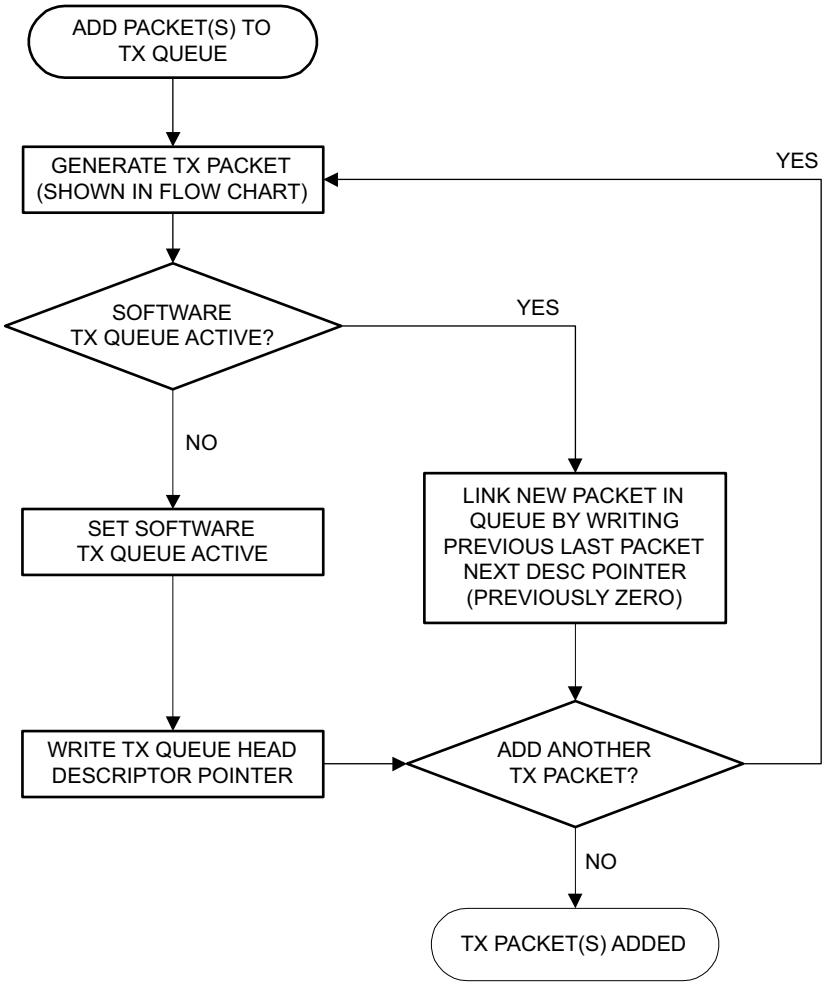
The EMAC module processes descriptors in linked lists as discussed in Section 32.2.6.1. The lists used by the EMAC are maintained by the application software through the use of the head descriptor pointer registers (HDP). The EMAC supports eight channels for transmit and eight channels for receive. The corresponding head descriptor pointers are:

- TX*n*HDP - Transmit Channel *n* DMA Head Descriptor Pointer Register
- RX*n*HDP - Receive Channel *n* DMA Head Descriptor Pointer Register

After an EMAC reset and before enabling the EMAC for send and receive, all 16 head descriptor pointer registers must be initialized to 0.

The EMAC uses a simple system to determine if a descriptor is currently owned by the EMAC or by the application software. There is a flag in the buffer descriptor flags called OWNER. When this flag is set, the packet that is referenced by the descriptor is considered to be owned by the EMAC. Note that ownership is done on a packet based granularity, not on descriptor granularity, so only SOP descriptors make use of the OWNER flag. As packets are processed, the EMAC patches the SOP descriptor of the corresponding packet and clears the OWNER flag. This is an indication that the EMAC has finished processing all descriptors up to and including the first with the EOP flag set, indicating the end of the packet (note this may only be one descriptor with both the SOP and EOP flags set).

To add a descriptor or a linked list of descriptors to an EMAC descriptor queue for the first time, the software application simply writes the pointer to the descriptor or first descriptor of a list to the corresponding HDP register. Note that the last descriptor in the list must have its “next” pointer cleared to 0. This is the only way the EMAC has of detecting the end of the list. Therefore, in the case where only a single descriptor is added, its “next descriptor” pointer must be initialized to 0.



The HDP must never be written to while a list is active. To add additional descriptors to a descriptor list already owned by the EMAC, the NULL “next” pointer of the last descriptor of the previous list is patched with a pointer to the first descriptor of the new list. The list of new descriptors to be appended to the existing list must itself be NULL terminated before the pointer patch is performed.

There is a potential race condition where the EMAC may read the “next” pointer of a descriptor as NULL in the instant before an application appends additional descriptors to the list by patching the pointer. This case is handled by the software application always examining the buffer descriptor flags of all EOP packets, looking for a special flag called end of queue (EOQ). The EOQ flag is set by the EMAC on the last descriptor of a packet when the descriptor’s “next” pointer is NULL. This is the way the EMAC indicates to the software application that it believes it has reached the end of the list. When the software application sees the EOQ flag set, the application may at that time submit the new list, or the portion of the appended list that was missed by writing the new list pointer to the same HDP that started the process.

This process applies when adding packets to a transmit list, and empty buffers to a receive list. Figure 32-7, Figure 32-8, and Figure 32-9 illustrate transmit operations.

32.2.6.3 Transmit and Receive EMAC Interrupts

The EMAC processes descriptors in linked list chains as discussed in Section 32.2.6.1, using the linked list queue mechanism discussed in Section 32.2.6.2.

The EMAC synchronizes descriptor list processing through the use of interrupts to the software application. The interrupts are controlled by the application using the interrupt masks, global interrupt enable, and the completion pointer register (CP). The CP is also called the interrupt acknowledge register.

The EMAC supports eight channels for transmit and eight channels for receive. The corresponding completion pointer registers are:

- TX*n*CP - Transmit Channel *n* Completion Pointer (Interrupt Acknowledge) Register
- RX*n*CP - Receive Channel *n* Completion Pointer (Interrupt Acknowledge) Register

These registers serve two purposes. When read, they return the pointer to the last descriptor that the EMAC has processed. When written by the software application, the value represents the last descriptor processed by the software application. When these two values do not match, the interrupt is active.

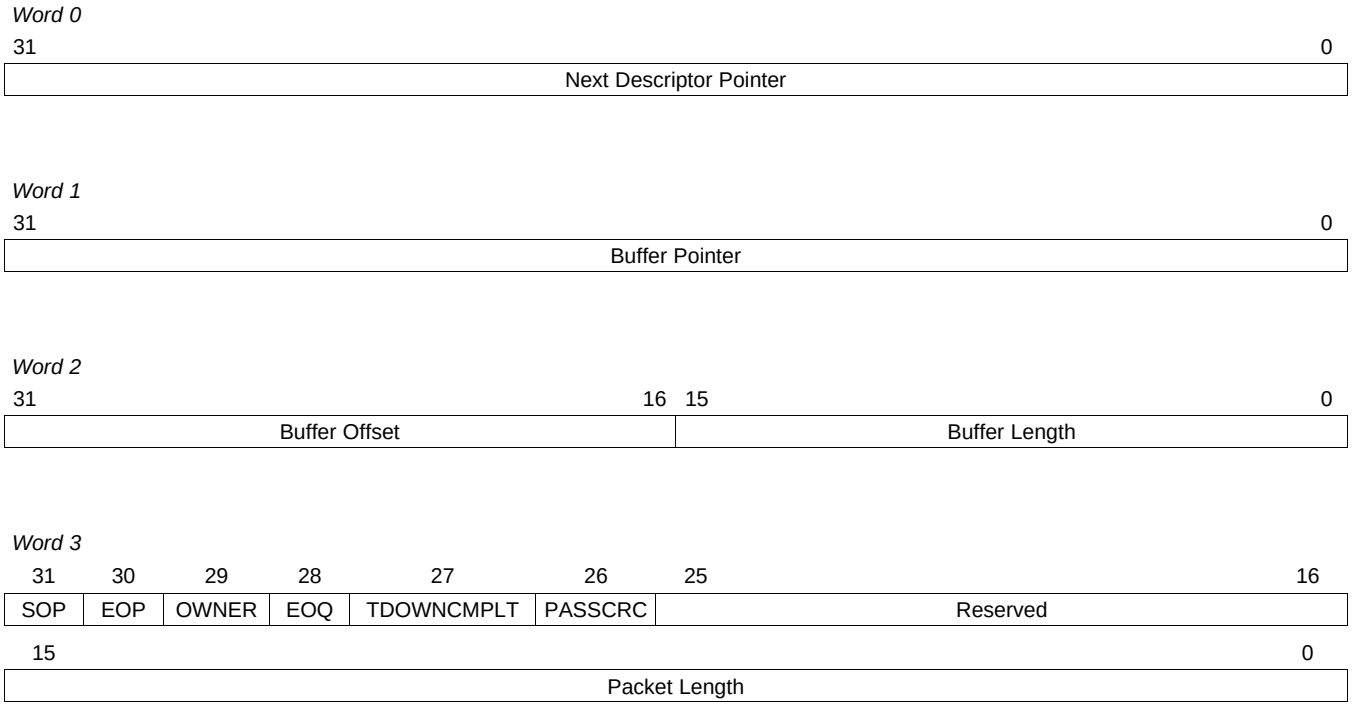
Interrupts in the EMAC control module are routed to the Vectored Interrupt Manager (VIM) as four separate interrupt requests. The interrupt configuration determines whether or not an active interrupt request actually interrupts the CPU. In general the following settings are required for basic EMAC transmit and receive interrupts:

1. EMAC transmit and receive interrupts are enabled by setting the mask registers RXINTMASKSET and TXINTMASKSET
2. Global interrupts are set in the EMAC control module: C0RXEN and C0TXEN
3. The VIM is configured to accept C0_RX_PULSE and C0_TX_PULSE interrupts from the EMAC control module
4. The normal mode (IRQ) interrupts are enabled in the Cortex-R4F CPU

Whether or not the interrupt is enabled, the current state of the receive or transmit channel interrupt can be examined directly by the software application reading the EMAC receive interrupt status (unmasked) register (RXINTSTATRAW) and transmit interrupt status (unmasked) register (TXINTSTATRAW).

After servicing transmit or receive interrupts, the application software must acknowledge both the EMAC and EMAC control module interrupts.

EMAC interrupts are acknowledged when the application software updates the value of TX*n*CP or RX*n*CP with a value that matches the internal value kept by the EMAC. This mechanism ensures that the application software never misses an EMAC interrupt because the interrupt acknowledgment is tied directly to the buffer descriptor processing.



EMAC control module interrupts are acknowledged when the application software writes the appropriate C0TX or C0RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). The MACEOIVECTOR behaves as an interrupt pulse interlock -- once the EMAC control module has issued an interrupt pulse to the CPU, it will not generate further pulses of the same type until the original pulse has been acknowledged.

32.2.6.4 Transmit Buffer Descriptor Format

A transmit (TX) buffer descriptor (Figure 32-10) is a contiguous block of four 32-bit data words aligned on a 32-bit boundary that describes a packet or a packet fragment. Example 32-1 shows the transmit buffer descriptor described by a C structure.

32.2.6.4.1 Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is 0, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

32.2.6.4.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

32.2.6.4.3 Buffer Offset

This 16-bit field indicates how many unused bytes are at the start of the buffer. For example, a value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer, while a value of 000Fh indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

Note that this value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set). It can not be used to specify the offset of subsequent packet fragments. Also, since the buffer pointer may point to any byte–aligned address, this field may be entirely superfluous, depending on the device driver architecture.

The range of legal values for this field is 0 to (Buffer Length – 1).

32.2.6.4.4 Buffer Length

This 16-bit field indicates how many valid data bytes are in the buffer. On single fragment packets, this value is also the total length of the packet data to be transmitted. If the buffer offset field is used, the offset bytes are not counted as part of this length. This length counts only valid data bytes. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

32.2.6.4.5 Packet Length

This 16-bit field specifies the number of data bytes in the entire packet. Any leading buffer offset bytes are not included. The sum of the buffer length fields of each of the packet's fragments (if more than one) must be equal to the packet length. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC. This value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set).

32.2.6.4.6 Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

Copyright © 2018, Texas Instruments Incorporated

32.2.6.4.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

32.2.6.4.8 Ownership (OWNER) Flag

When set, this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

32.2.6.4.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

32.2.6.4.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission.

Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

32.2.6.4.11 Pass CRC (PASSCRC) Flag

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC.

When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

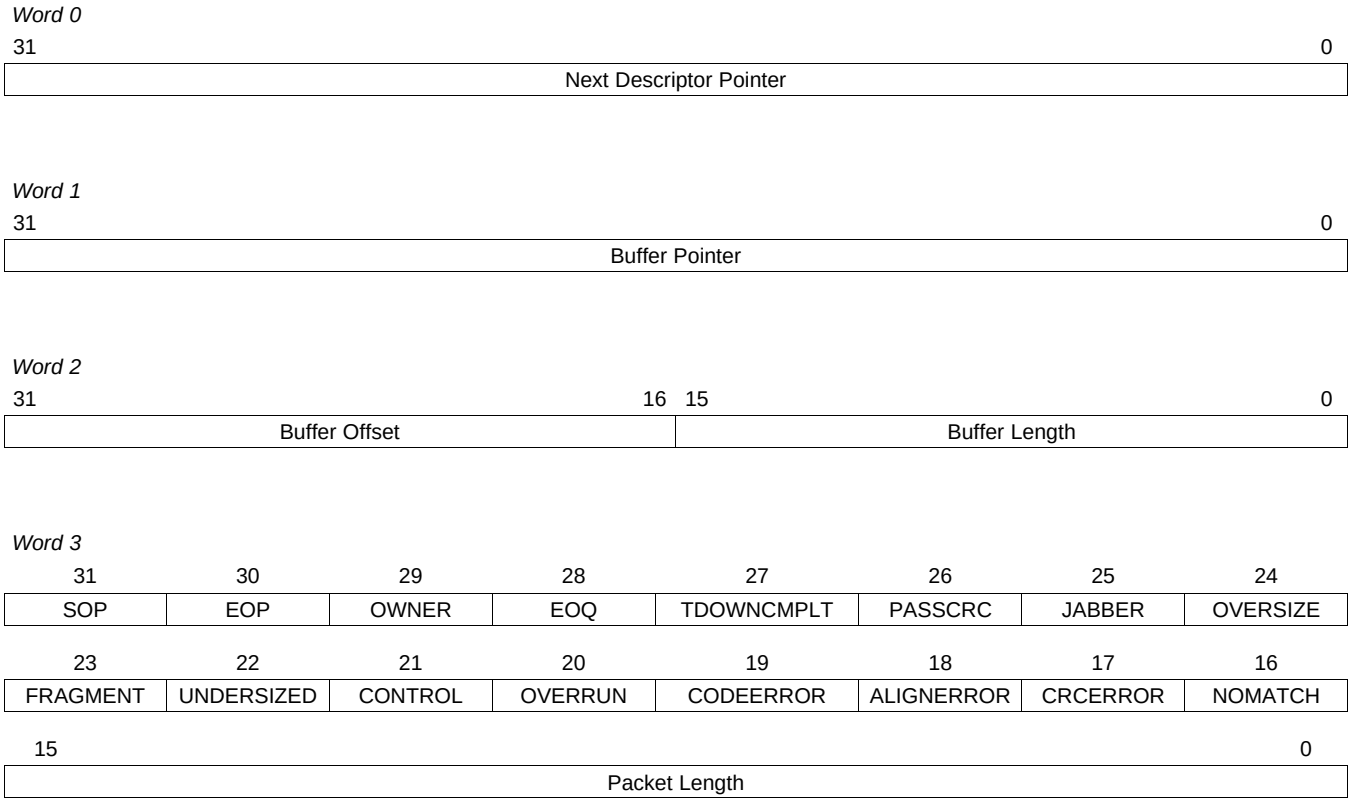
Copyright © 2018, Texas Instruments Incorporated

32.2.6.5 Receive Buffer Descriptor Format

A receive (RX) buffer descriptor (Figure 32-11) is a contiguous block of four 32-bit data words aligned on a 32-bit boundary that describes a packet or a packet fragment. Example 32-2 shows the receive buffer descriptor described by a C structure.

32.2.6.5.1 Next Descriptor Pointer

This pointer points to the 32–bit word aligned memory address of the next buffer descriptor in the receive queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is 0, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.



The value of pNext should never be altered once the descriptor is in an active receive queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more empty buffers can be added to the pool, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the receiver will halt the receive channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

32.2.6.5.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

#define EMAC_DSC_FLAG_NOMATCH 0x00010000u
```

32.2.6.5.3 Buffer Offset

This 16-bit field must be initialized to 0 by the software application before adding the descriptor to a receive queue.

Whether or not this field is updated depends on the setting of the RXBUFFEROFFSET register. When the offset register is set to a nonzero value, the received packet is written to the packet buffer at an offset given by the value of the register, and this value is also written to the buffer offset field of the descriptor.

When a packet is fragmented over multiple buffers because it does not fit in the first buffer supplied, the buffer offset only applies to the first buffer in the list, which is where the start of packet (SOP) flag is set in the corresponding buffer descriptor. In other words, the buffer offset field is only updated by the EMAC on SOP descriptors.

The range of legal values for the BUFFEROFFSET register is 0 to (Buffer Length – 1) for the smallest value of buffer length for all descriptors in the list.

Copyright © 2018, Texas Instruments Incorporated

32.2.6.5.4 Buffer Length

This 16-bit field is used for two purposes:

- Before the descriptor is first placed on the receive queue by the application software, the buffer length field is first initialized by the software to have the physical size of the empty data buffer pointed to by the buffer pointer field.
- After the empty buffer has been processed by the EMAC and filled with received data bytes, the buffer length field is updated by the EMAC to reflect the actual number of valid data bytes written to the buffer.

32.2.6.5.5 Packet Length

This 16-bit field specifies the number of data bytes in the entire packet. This value is initialized to 0 by the software application for empty packet buffers. The value is filled in by the EMAC on the first buffer used for a given packet. This is signified by the EMAC setting a start of packet (SOP) flag. The packet length is set by the EMAC on all SOP buffer descriptors.

32.2.6.5.6 Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

32.2.6.5.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

32.2.6.5.8 Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

32.2.6.5.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

32.2.6.5.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

Copyright © 2018, Texas Instruments Incorporated

32.2.6.5.11 Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

32.2.6.5.12 Jabber Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

32.2.6.5.13 Oversize Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an oversized frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

32.2.6.5.14 Fragment Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

32.2.6.5.15 Undersized Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is undersized and was not discarded because the RXCSFEN bit was set in the RXMBPENABLE.

32.2.6.5.16 Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RXCMFEN bit was set in the RXMBPENABLE.

32.2.6.5.17 Overrun Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

32.2.6.5.18 Code Error (CODEERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a code error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

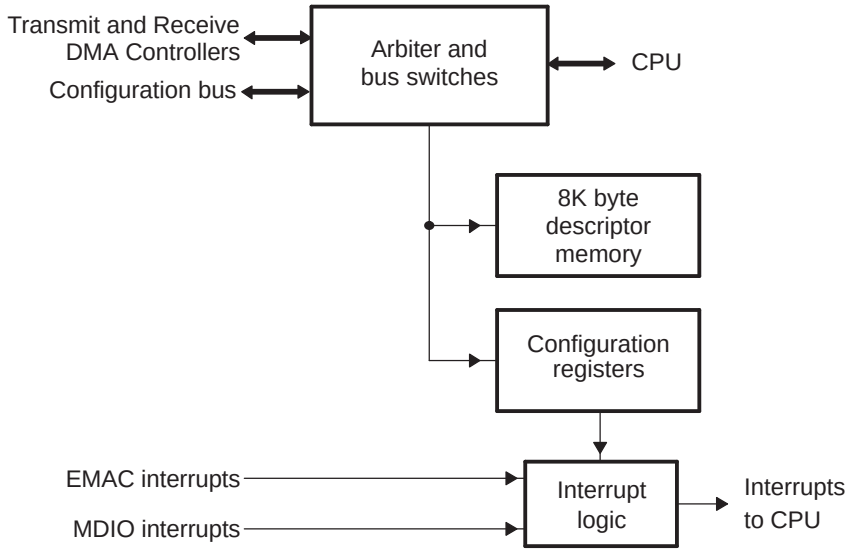
32.2.6.5.19 Alignment Error (ALIGNERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained an alignment error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

32.2.6.5.20 CRC Error (CRCERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a CRC error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

32.2.6.5.21 No Match (NOMATCH) Flag



This flag is set by the EMAC in the SOP buffer descriptor, if the received packet did not pass any of the EMAC's address match criteria and was not discarded because the RXCAFEN bit was set in the RXMBPENABLE. Although the packet is a valid Ethernet data packet, it was only received because the EMAC is in promiscuous mode.

32.2.7 EMAC Control Module

The EMAC control module (Figure 32-12) interfaces the EMAC and MDIO modules to the rest of the system, and also provides a local memory space to hold EMAC packet buffer descriptors. Local memory is used to help avoid contention with device memory spaces. Other functions include the bus arbiter and the interrupt logic control.

Figure 32-12. EMAC Control Module Block Diagram

32.2.7.1 Internal Memory

The EMAC control module includes 8K bytes of internal memory (CPPI buffer descriptor memory). The internal memory block is essential for allowing the EMAC to operate more independently of the CPU. It also prevents memory underflow conditions when the EMAC issues read or write requests to descriptor memory. (Memory accesses to read or write the actual Ethernet packet data are protected by the EMAC's internal FIFOs).

A descriptor is a 16-byte memory structure that holds information about a single Ethernet packet buffer, which may contain a full or partial Ethernet packet. Thus with the 8K memory block provided for descriptor storage, the EMAC module can send and received up to a combined 512 packets before it needs to be serviced by application or driver software.

32.2.7.2 Interrupt Control

Interrupt conditions generated by the EMAC and MDIO modules are combined into four interrupt signals that are routed to the Vectored Interrupt Manager (VIM); the VIM then relays the interrupt signals to the CPU. The EMAC control module uses two sets of registers to control the interrupt signals to the CPU:

- C0RXTHRESHEN, C0RXEN, C0TXEN, and C0MISCEN registers enable the pulse signals that are mapped to the VIM
- INTCONTROL, C0RXIMAX, and C0TXIMAX registers enable interrupt pacing to limit the number of interrupt pulses generated per millisecond

Interrupts must be acknowledged by writing the appropriate value to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). The MACEOIVECTOR behaves as an interrupt pulse interlock -- once the EMAC control module has issued an interrupt pulse to the CPU, it will not generate further pulses of the same type until the original pulse has been acknowledged.

Copyright © 2018, Texas Instruments Incorporated

32.2.7.3 Bus Arbiter

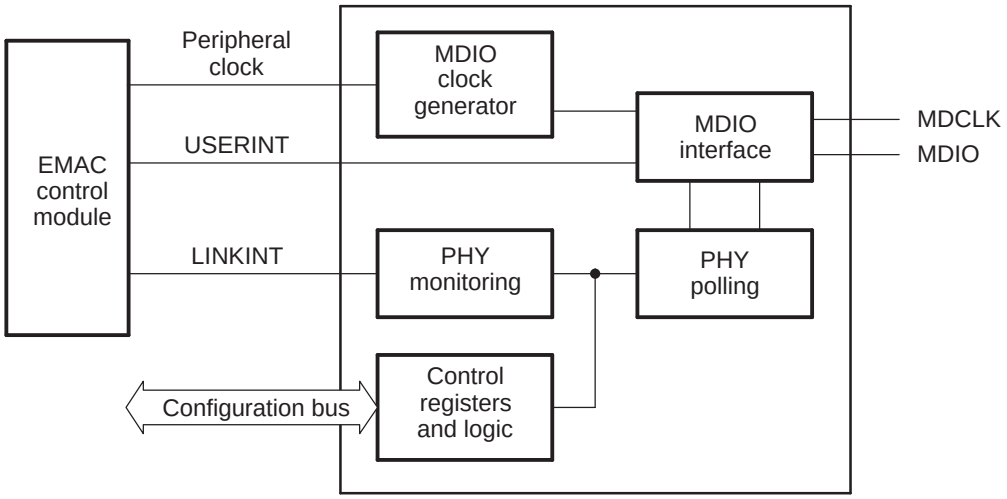
The EMAC control module bus arbiter operates transparently to the rest of the system. It is used:

- To arbitrate between the CPU and EMAC buses for access to internal descriptor memory.
- To arbitrate between internal EMAC buses for access to system memory.

32.2.8 MDIO Module

The MDIO module is used to manage up to 32 physical layer (PHY) devices connected to the Ethernet Media Access Controller (EMAC). The device supports a single PHY being connected to the EMAC at any given time. The MDIO module is designed to allow almost transparent operation of the MDIO interface with little maintenance from the CPU.

The MDIO module continuously polls 32 MDIO addresses in order to enumerate all PHY devices in the system. Once a PHY device has been detected, the MDIO module reads the MDIO PHY link status register (LINK) to monitor the PHY link state. Link change events are stored in the MDIO module, which can interrupt the CPU. This storing of the events allows the CPU to poll the link status of the PHY device without continuously performing MDIO module accesses. However, when the CPU must access the MDIO module for configuration and negotiation, the MDIO module performs the MDIO read or write operation independent of the CPU. This independent operation allows the processor to poll for completion or interrupt the CPU once the operation has completed.



The MDIO module does not support the "Clause 45" interface.

32.2.8.1 MDIO Module Components

The MDIO module (Figure 32-13) interfaces to the PHY components through two MDIO pins (MDIO_CLK and MDIO), and to the CPU through the EMAC control module and the configuration bus. The MDIO module consists of the following logical components:

- MDIO clock generator
- Global PHY detection and link state monitoring
- Active PHY monitoring
- PHY register user access

Figure 32-13. MDIO Module Block Diagram

Copyright © 2018, Texas Instruments Incorporated

32.2.8.1.1 MDIO Clock Generator

The MDIO clock generator controls the MDIO clock based on a divide-down of the VCLK3 peripheral clock in the EMAC control module. The MDIO clock is specified to run up to 2.5 MHz, although typical operation would be 1.0 MHz. Since the VCLK3 peripheral clock frequency is configurable, the application software or driver controls the divide-down amount. See the device datasheet for peripheral clock speed specifications.

32.2.8.1.2 Global PHY Detection and Link State Monitoring

The MDIO module continuously polls all 32 MDIO addresses in order to enumerate the PHY devices in the system. The module tracks whether or not a PHY on a particular address has responded, and whether or not the PHY currently has a link. Using this information allows the software application to quickly determine which MDIO address the PHY is using.

32.2.8.1.3 Active PHY Monitoring

Once a PHY candidate has been selected for use, the MDIO module transparently monitors its link state by reading the MDIO PHY link status register (LINK). Link change events are stored on the MDIO device and can optionally interrupt the CPU. This allows the system to poll the link status of the PHY device without continuously performing costly MDIO accesses.

32.2.8.1.4 PHY Register User Access

When the CPU must access MDIO for configuration and negotiation, the PHY access module performs the actual MDIO read or write operation independent of the CPU. This allows the CPU to poll for completion or receive an interrupt when the read or write operation has been performed. The user access registers USERACCESS*n* allows the software to submit the access requests for the PHY connected to the device.

Copyright © 2018, Texas Instruments Incorporated

32.2.8.2 MDIO Module Operational Overview

The MDIO module implements the 802.3 serial management interface to interrogate and control an Ethernet PHY, using a shared two-wired bus. It separately performs autodetection and records the current link status of up to 32 PHYs, polling all 32 MDIO addresses.

Application software uses the MDIO module to configure the autonegotiation parameters of the PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC.

In this device, the Ethernet PHY attached to the system can be directly controlled and queried. The Media Independent Interface (MII) address of this PHY device is specified in one of the PHYADRMON bits in the MDIO user PHY select register (USERPHYSEL*n*). The MDIO module can be programmed to trigger a CPU interrupt on a PHY link change event, by setting the LINKINTENB bit in USERPHYSEL*n*. Reads and writes to registers in this PHY device are performed using the MDIO user access register (USERACCESS*n*).

The MDIO module powers-up in an idle state until specifically enabled by setting the ENABLE bit in the MDIO control register (CONTROL). At this time, the MDIO clock divider and preamble mode selection are also configured. The MDIO preamble is enabled by default, but can be disabled when the connected PHY does not require it. Once the MDIO module is enabled, the MDIO interface state machine continuously polls the PHY link status (by reading the generic status register) of all possible 32 PHY addresses and records the results in the MDIO PHY alive status register (ALIVE) and MDIO PHY link status register (LINK). The corresponding bit for the connected PHY (0-31) is set in ALIVE, if the PHY responded to the read request. The corresponding bit is set in LINK, if the PHY responded and also is currently linked. In addition, any PHY register read transactions initiated by the application software using USERACCESS*n* causes ALIVE to be updated.

The USERPHYSEL*n* is used to track the link status of the connected PHY address. A change in the link status of the PHY being monitored sets the appropriate bit in the MDIO link status change interrupt registers (LINKINTRAW and LINKINTMASKED), if enabled by the LINKINTENB bit in USERPHYSEL*n*.

While the MDIO module is enabled, the host issues a read or write transaction over the MII management interface using the DATA, PHYADR, REGADR, and WRITE bits in USERACCESS*n*. When the application sets the GO bit in USERACCESS*n*, the MDIO module begins the transaction without any further intervention from the CPU. Upon completion, the MDIO module clears the GO bit and sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS*n* used. The corresponding USERINTMASKED bit (0 or 1) in the MDIO user command complete interrupt register (USERINTMASKED) may also be set, depending on the mask setting configured in the MDIO user command complete interrupt mask set register (USERINTMASKSET) and the MDIO user interrupt mask clear register (USERINTMASKCLEAR).

A round-robin arbitration scheme is used to schedule transactions that may be queued using both USERACCESS0 and USERACCESS1. The application software must check the status of the GO bit in USERACCESS*n* before initiating a new transaction, to ensure that the previous transaction has completed. The application software can use the ACK bit in USERACCESS*n* to determine the status of a read transaction.

Copyright © 2018, Texas Instruments Incorporated

32.2.8.2.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO control register (CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in CONTROL.
3. The MDIO PHY alive status register (ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (USERPHYSEL*n*), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) to use the MDIO user access register (USERACCESS*n*). Since only one PHY is used in this device, the application software can use one USERACCESS*n* to trigger a completion interrupt; the other USERACCESS*n* is not setup.

32.2.8.2.2 Writing Data To a PHY Register

The MDIO module includes a user access register (USERACCESS*n*) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS*n*) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in USERACCESS*n* corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in USERACCESS*n* for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS*n* used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

32.2.8.2.3 Reading Data From a PHY Register

The MDIO module includes a user access register (USERACCESS*n*) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS*n*) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in USERACCESS*n* corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in USERACCESS*n* after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in USERACCESS*n*. Once the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS*n* used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

32.2.8.2.4 Example of MDIO Register Access Code

The MDIO module uses the MDIO user access register (USERACCESS*n*) to access the PHY control registers. Software functions that implement the access process may simply be the following four macros:

- PHYREG_read(regadr, phyadr) — Start the process of reading a PHY register
- PHYREG_write(regadr, phyadr, data) — Start the process of writing a PHY register
- PHYREG_wait( ) — Synchronize operation (make sure read/write is idle)
- PHYREG_waitResults(results) — Wait for read to complete and return data read

Note that it is not necessary to wait after a write operation, as long as the status is checked before every operation to make sure the MDIO hardware is idle. An alternative approach is to call PHYREG_wait() after every write, and PHYREG_waitResults( ) after every read, then the hardware can be assumed to be idle when starting a new operation.

The implementation of these macros using the chip support library (CSL) is shown in Example 32-3 (USERACCESS0 is assumed).

Note that this implementation does not check the ACK bit in USERACCESS*n* on PHY register reads (does not follow the procedure outlined in Section 32.2.8.2.3). Since the MDIO PHY alive status register (ALIVE) is used to initially select a PHY, it is assumed that the PHY is acknowledging read operations. It is possible that a PHY could become inactive at a future point in time. An example of this would be a PHY that can have its MDIO addresses changed while the system is running. It is not very likely, but this condition can be tested by periodically checking the PHY state in ALIVE.

Example 32-3. MDIO Register Access Macros

```
#define PHYREG_read(regadr, phyadr)
    MDIO_REGS->USERACCESS0 =
        CSL_FMK(MDIO_USERACCESS0_GO,1u)                        | /
        CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)                | /
        CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)
#define PHYREG_write(regadr, phyadr, data)
    MDIO_REGS->USERACCESS0 =
        CSL_FMK(MDIO_USERACCESS0_GO,1u)                        | /
        CSL_FMK(MDIO_USERACCESS0_WRITE,1)                      | /
        CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)                | /
        CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)                | /
        CSL_FMK(MDIO_USERACCESS0_DATA, data)
#define PHYREG_wait()
    while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_GO) )
#define PHYREG_waitResults( results ) {
    while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_GO) );
results = CSL_FEXT(MDIO_REGS->USERACCESS0, MDIO_USERACCESS0_DATA); }
```

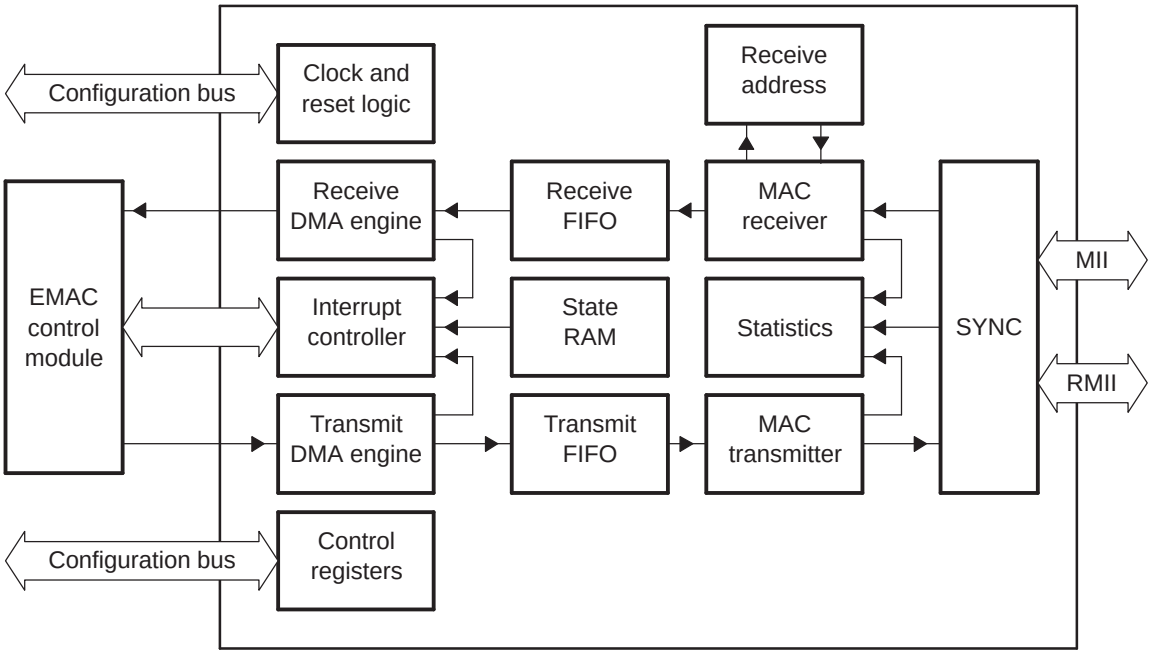
32.2.9 EMAC Module



This section discusses the architecture and basic function of the EMAC module.

32.2.9.1 EMAC Module Components

The EMAC module (Figure 32-14) interfaces to the outside world through the Media Independent Interface (MII) or Reduced Media Independent Interface (RMII). The interface between the EMAC module and the system core is provided through the EMAC control module. The EMAC consists of the following logical components:

- The receive path includes: receive DMA engine, receive FIFO, and MAC receiver
- The transmit path includes: transmit DMA engine, transmit FIFO, and MAC transmitter
- Statistics logic
- State RAM
- Interrupt controller
- Control registers and logic
- Clock and reset logic

Figure 32-14. EMAC Module Block Diagram

32.2.9.1.1 Receive DMA Engine

The receive DMA engine is the interface between the receive FIFO and the system core. It interfaces to the CPU through the bus arbiter in the EMAC control module. This DMA engine is totally independent of the device DMA.

32.2.9.1.2 Receive FIFO

The receive FIFO consists of three cells of 64-bytes each and associated control logic. The FIFO buffers receive data in preparation for writing into packet buffers in device memory.

Copyright © 2018, Texas Instruments Incorporated

32.2.9.1.3 MAC Receiver

The MAC receiver detects and processes incoming network frames, de-frames them, and puts them into the receive FIFO. The MAC receiver also detects errors and passes statistics to the statistics RAM.

32.2.9.1.4 Transmit DMA Engine

The transmit DMA engine is the interface between the transmit FIFO and the CPU. It interfaces to the CPU through the bus arbiter in the EMAC control module.

32.2.9.1.5 Transmit FIFO

The transmit FIFO consists of three cells of 64-bytes each and associated control logic. The FIFO buffers data in preparation for transmission.

32.2.9.1.6 MAC Transmitter

The MAC transmitter formats frame data from the transmit FIFO and transmits the data using the CSMA/CD access protocol. The frame CRC can be automatically appended, if required. The MAC transmitter also detects transmission errors and passes statistics to the statistics registers.

32.2.9.1.7 Statistics Logic

The Ethernet statistics are counted and stored in the statistics logic RAM. This statistics RAM keeps track of 36 different Ethernet packet statistics.

32.2.9.1.8 State RAM

State RAM contains the head descriptor pointers and completion pointers registers for both transmit and receive channels.

32.2.9.1.9 EMAC Interrupt Controller

The interrupt controller contains the interrupt related registers and logic. The 26 raw EMAC interrupts are input to this submodule and masked module interrupts are output.

32.2.9.1.10 Control Registers and Logic

The EMAC is controlled by a set of memory-mapped registers. The control logic also signals transmit, receive, and status related interrupts to the CPU through the EMAC control module.

32.2.9.1.11 Clock and Reset Logic

The clock and reset submodule generates all the EMAC clocks and resets. For more details on reset capabilities, see Section 32.2.15.1.

32.2.9.2 EMAC Module Operational Overview

After reset, initialization, and configuration, the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the state RAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory. The DMA controller writes the packet into the transmit FIFO in bursts of 64-byte cells. When the threshold number of cells, configurable using the TXCELLTHRESH bit in the FIFO control register (FIFOCONTROL), have been written to the transmit FIFO, or a complete packet, whichever is smaller, the MAC transmitter then initiates the packet transmission. The SYNC block transmits the packet over the MII or RMII interfaces in accordance with the 802.3 protocol. Transmit statistics are counted by the statistics block.

Copyright © 2018, Texas Instruments Incorporated

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The SYNC submodule receives packets and strips off the Ethernet related protocol. The packet data is input to the MAC receiver, which checks for address match and processes errors. Accepted packets are then written to the receive FIFO in bursts of 64-byte cells. The receive DMA controller then writes the packet data to memory. Receive statistics are counted by the statistics block.

The EMAC module operates independently of the CPU. It is configured and controlled by its register set mapped into device memory. Information about data packets is communicated by use of 16-byte descriptors that are placed in an 8K-byte block of RAM in the EMAC control module (CPPI buffer descriptor memory).

For transmit operations, each 16-byte descriptor describes a packet or packet fragment in the system's internal or external memory. For receive operations, each 16-byte descriptor represents a free packet buffer or buffer fragment. On both transmit and receive, an Ethernet packet is allowed to span one or more memory fragments, represented by one 16-byte descriptor per fragment. In typical operation, there is only one descriptor per receive buffer, but transmit packets may be fragmented, depending on the software architecture.

An interrupt is issued to the CPU whenever a transmit or receive operation has completed. However, it is not necessary for the CPU to service the interrupt while there are additional resources available. In other words, the EMAC continues to receive Ethernet packets until its receive descriptor list has been exhausted. On transmit operations, the transmit descriptors need only be serviced to recover their associated memory buffer. Thus, it is possible to delay servicing of the EMAC interrupt if there are real-time tasks to perform.

Eight channels are supplied for both transmit and receive operations. On transmit, the eight channels represent eight independent transmit queues. The EMAC can be configured to treat these channels as an equal priority "round-robin" queue or as a set of eight fixed-priority queues. On receive, the eight channels represent eight independent receive queues with packet classification. Packets are classified based on the destination MAC address. Each of the eight channels is assigned its own MAC address, enabling the EMAC module to act like eight virtual MAC adapters. Also, specific types of frames can be sent to specific channels. For example, multicast, broadcast, or other (promiscuous, error, etc.), can each be received on a specific receive channel queue.

The EMAC keeps track of 36 different statistics, plus keeps the status of each individual packet in its corresponding packet descriptor.

32.2.10 MAC Interface

The following sections discuss the operation of the Media Independent Interface (MII) and Reduced Media Independent Interface (RMII) in 10 Mbps and 100 Mbps mode. An IEEE 802.3 compliant Ethernet MAC controls the interface.

32.2.10.1 Data Reception

32.2.10.1.1 Receive Control

Data received from the PHY is interpreted and output to the EMAC receive FIFO. Interpretation involves detection and removal of the preamble and start-of-frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation. Address detection and frame filtering is performed outside the MAC interface.

32.2.10.1.2 Receive Inter-Frame Interval

The 802.3 standard requires an interpacket gap (IPG), which is 96 bit times. However, the EMAC can tolerate a reduced IPG of 8 bit times with a correct preamble and start frame delimiter. This interval between frames must comprise (in the following order):

1. An Interpacket Gap (IPG).
2. A 7-byte preamble (all bytes 55h).
3. A 1-byte start of frame delimiter (5Dh).

Copyright © 2018, Texas Instruments Incorporated

32.2.10.1.3 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the EMAC from further frame reception. Two forms of receive buffer flow control are available:

- Collision-based flow control for half-duplex mode
- IEEE 802.3x pause frames flow control for full-duplex mode

In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control prevents reception of frames on the EMAC until all of the triggering conditions clear, at which time frames may again be received by the EMAC.

Receive flow control is enabled by the RXBUFFERFLOWEN bit in the MAC control register (MACCONTROL). The EMAC is configured for collision or IEEE 802.3X flow control using the FULLDUPLEX bit in MACCONTROL. Receive flow control is triggered when the number of free buffers in any enabled receive channel free buffer count register (RX*n*FREEBUFFER) is less than or equal to the receive channel flow control threshold register (RX*n*FLOWTHRESH) value. Receive flow control is independent of receive QOS, except that both use the free buffer values.

32.2.10.1.3.1 Collision-Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in half-duplex mode (the FULLDUPLEX bit is cleared in MACCONTROL). When receive flow control is enabled and triggered, the EMAC generates collisions for received frames. The jam sequence transmitted is the 12-byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3h. The jam sequence begins no later than approximately as the source address starts to be received. Note that these forced collisions are not limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm.

Receive flow control does not depend on the value of the incoming frame destination address. A collision is generated for any incoming packet, regardless of the destination address, if any EMAC enabled channel's free buffer register value is less than or equal to the channel's flow threshold value.

32.2.10.1.3.2 IEEE 802.3x-Based Receive Buffer Flow Control

IEEE 802.3x-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in full-duplex mode (the FULLDUPLEX bit is set in MACCONTROL). When receive flow control is enabled and triggered, the EMAC transmits a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The EMAC transmits a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle or following the completion of the frame currently being transmitted). The pause frame contains the maximum possible value for the pause time (FFFFh). The EMAC counts the receive pause frame time (decrements FF00h to 0) and retransmits an outgoing pause frame, if the count reaches 0. When the flow control request is removed, the EMAC transmits a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval are received normally (provided the receive FIFO is not full).

Pause frames are transmitted if enabled and triggered, regardless of whether or not the EMAC is observing the pause time period from an incoming pause frame.

The EMAC transmits pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01h.
- The 48-bit source address (set using the MACSRCADDRLO and MACSRCADDRHI registers).
- The 16-bit length/type field containing the value 88.08h.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time value of FF.FFh. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request have a pause time value of 00.00h.
- Zero padding to 64-byte data length (EMAC transmits only 64-byte pause frames).

Copyright © 2018, Texas Instruments Incorporated

- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

If the RXBUFFERFLOWEN bit in MACCONTROL is cleared to 0 while the pause time is nonzero, then the pause time is cleared to 0 and a zero count pause frame is sent.

32.2.10.2 Data Transmission

The EMAC passes data to the PHY from the transmit FIFO (when enabled). Data is synchronized to the transmit clock rate. Transmission begins when there are TXCELLTHRESH cells of 64 bytes each, or a complete packet, in the FIFO.

32.2.10.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted), the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full-duplex mode, the carrier sense (MII_CRS) and collision-sensing (MII_COL) modes are disabled.

32.2.10.2.2 CRC Insertion

If the SOP buffer descriptor PASSCRC flag is cleared, the EMAC generates and appends a 32-bit Ethernet CRC onto the transmitted data. For the EMAC-generated CRC case, a CRC (or placeholder) at the end of the data is allowed but not required. The buffer byte count value should not include the CRC bytes, if they are present.

If the SOP buffer descriptor PASSCRC flag is set, then the last four bytes of the transmit data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the buffer byte count value. The MAC performs no error checking on the outgoing CRC.

32.2.10.2.3 Adaptive Performance Optimization (APO)

The EMAC incorporates adaptive performance optimization (APO) logic that may be enabled by setting the TXPACE bit in the MAC control register (MACCONTROL). Transmission pacing to enhance performance is enabled when the TXPACE bit is set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions), thereby, increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions, or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision, or excessive collision), the pacing counter is decremented by 1, down to 0.

With pacing enabled, a new frame is permitted to immediately (after one interpacket gap) attempt transmission only if the pacing counter is 0. If the pacing counter is nonzero, the frame is delayed by the pacing delay of approximately four interpacket gap (IPG)delays. APO only affects the IPG preceding the first attempt at transmitting a frame; APO does not affect the back-off algorithm for retransmitted frames.

32.2.10.2.4 Interpacket-Gap (IPG) Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision and MII_CRS is deasserted within approximately 48 bit times of MII_TXEN being deasserted, then 96 bit times is measured from MII_TXEN. If the frame suffered a collision or MII_CRS is not deasserted until more than approximately 48 bit times after MII_TXEN is deasserted, then 96 bit times (approximately, but not less) is measured from MII_CRS.

32.2.10.2.5 Back Off

The EMAC implements the 802.3 binary exponential back-off algorithm.

Copyright © 2018, Texas Instruments Incorporated

32.2.10.2.6 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the EMAC from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TXFLOWEN bits in the MAC control register (MACCONTROL) are set. Pause frames are not acted upon in half-duplex mode. Pause frame action is taken if enabled, but normally the frame is filtered and not transferred to memory. MAC control frames are transferred to memory, if the RXCMFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) is set. The TXFLOWEN and FULLDUPLEX bits affect whether or not MAC control frames are acted upon, but they have no affect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC control frames with an opcode field of 0001h. Incoming pause frames are only acted upon by the EMAC if:

- TXFLOWEN bit is set in MACCONTROL
- The frame's length is 64 to RXMAXLEN bytes inclusive
- The frame contains no CRC error or align/code errors

The pause time value from valid frames is extracted from the two bytes following the opcode. The pause time is loaded into the EMAC transmit pause timer and the transmit pause time period begins. If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- If the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer immediately expires, or
- If the new pause time value is 0, then the transmit pause timer immediately expires, else
- The EMAC transmit pause timer immediately is set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame is discarded).

If the TXFLOWEN bit in MACCONTROL is cleared, then the pause timer immediately expires.

The EMAC does not start the transmission of a new data frame any sooner than 512 bit-times after a pause frame with a nonzero pause time has finished being received (MII_RXDV going inactive). No transmission begins until the pause timer has expired (the EMAC may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received is completed and unaffected.

Incoming pause frames consist of:

- A 48-bit destination address equal to one of the following:
  - The reserved multicast destination address 01.80.C2.00.00.01h
  - Any EMAC 48-bit unicast address. Pause frames are accepted, regardless of whether the channel is enabled or not.
- The 16-bit length/type field containing the value 88.08h.
- The 48-bit source address of the transmitting device.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The EMAC recognizes any pause frame between 64 bytes and RXMAXLEN bytes in length.

32.2.10.2.7 Speed, Duplex, and Pause Frame Support

The MAC operates at 10 Mbps or 100 Mbps, in half-duplex or full-duplex mode, and with or without pause frame support as configured by the host.

Copyright © 2018, Texas Instruments Incorporated

32.2.11 Packet Receive Operation

32.2.11.1 Receive DMA Host Configuration

To configure the receive DMA for operation the host must:

- Initialize the receive addresses.
- Initialize the receive channel *n* DMA head descriptor pointer registers (RX*n*HDP) to 0.
- Write the MAC address hash *n* registers (MACHASH1 and MACHASH2), if multicast addressing is desired.
- If flow control is to be enabled, initialize:
  - the receive channel *n* free buffer count registers (RX*n*FREEBUFFER)
  - the receive channel *n* flow control threshold register (RX*n*FLOWTHRESH)
  - the receive filter low priority frame threshold register (RXFILTERLOWTHRESH)
- Enable the desired receive interrupts using the receive interrupt mask set register (RXINTMASKSET) and the receive interrupt mask clear register (RXINTMASKCLEAR).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Write the receive buffer offset register (RXBUFFEROFFSET) value (typically 0).
- Setup the receive channel(s) buffer descriptors and initialize RX*n*HDP.
- Enable the receive DMA controller by setting the RXEN bit in the receive control register (RXCONTROL).
- Configure and enable the receive operation, as desired, in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) and by using the receive unicast set register (RXUNICASTSET) and the receive unicast clear register (RXUNICASTCLEAR).

32.2.11.2 Receive Channel Enabling

Each of the eight receive channels has an enable bit (RXCH*n*EN) in the receive unicast set register (RXUNICASTSET) that is controlled using RXUNICASTSET and the receive unicast clear register (RXUNICASTCLEAR). The RXCH*n*EN bits determine whether the given channel is enabled (when set to 1) to receive frames with a matching unicast or multicast destination address.

The RXBROADEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) determines if broadcast frames are enabled or filtered. If broadcast frames are enabled (when set to 1), then they are copied to only a single channel selected by the RXBROADCH bit in RXMBPENABLE.

The RXMULTEN bit in RXMBPENABLE determines if hash matching multicast frames are enabled or filtered. Incoming multicast addresses (group addresses) are hashed into an index in the hash table. If the indexed bit is set then the frame hash matches and will be transferred to the channel selected by the RXMULTCH bit in RXMBPENABLE when multicast frames are enabled. The multicast hash bits are set in the MAC address hash *n* registers (MACHASH1 and MACHASH2).

The RXPROMCH bit in RXMBPENABLE selects the promiscuous channel to receive frames selected by the RXCMFEN, RXCSFEN, RXCEFEN, and RXCAFEN bits. These four bits allow reception of MAC control frames, short frames, error frames, and all frames (promiscuous), respectively.

32.2.11.3 Receive Address Matching

All eight MAC addresses corresponding to the eight receive channels share the upper 40 bits. Only the lower byte is unique for each address. All eight receive addresses should be initialized, because pause frames are acted upon regardless of whether a channel is enabled or not.

A MAC address is written by first writing the address number (channel) to be written into the MAC index register (MACINDEX). The upper 32 bits of address are then written to the MAC address high bytes register (MACADDRHI), which is followed by writing the lower 16 bits of address to the MAC address low bytes register (MACADDRLO). Since all eight MAC addresses share the upper 40 bits of address, MACADDRHI needs to be written only the first time (for the first channel configured).

Copyright © 2018, Texas Instruments Incorporated

32.2.11.4 Hardware Receive QOS Support

Hardware receive quality of service (QOS) is supported, when enabled, by the Tag Protocol Identifier format and the associated Tag Control Information (TCI) format priority field. When the incoming frame length/type value is equal to 81.00h, the EMAC recognizes the frame as an Ethernet Encoded Tag Protocol Type. The two octets immediately following the protocol type contain the 16-bit TCI field. Bits 15-13 of the TCI field contain the received frames priority (0 to 7). The received frame is a low-priority frame, if the priority value is 0 to 3; the received frame is a high-priority frame, if the priority value is 4 to 7. All frames that have a length/type field value not equal to 81.00h are low-priority frames. Received frames that contain priority information are determined by the EMAC as:

- A 48-bit (6 bytes) destination address equal to:
  - The destination station's individual unicast address.
  - The destination station's multicast address (MACHASH1 and MACHASH2).
  - The broadcast address of all ones.
- A 48-byte (6 bytes) source address.
- The 16-bit (2 bytes) length/type field containing the value 81.00h.
- The 16-bit (2 bytes) TCI field with the priority field in the upper 3 bits.
- Data bytes
- The 4 bytes CRC.

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) and the receive channel *n* free buffer count registers (RX*n*FREEBUFFER) are used in conjunction with the priority information to implement receive hardware QOS. Low-priority frames are filtered if the number of free buffers (RX*n*FREEBUFFER) for the frame channel is less than or equal to the filter low threshold (RXFILTERLOWTHRESH) value. Hardware QOS is enabled by the RXQOSEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

32.2.11.5 Host Free Buffer Tracking

The host must track free buffers for each enabled channel (including unicast, multicast, broadcast, and promiscuous), if receive QOS or receive flow control is used. Disabled channel free buffer values are do not cares. During initialization, the host should write the number of free buffers for each enabled channel to the appropriate receive channel *n* free buffer count registers (RX*n*FREEBUFFER). The EMAC decrements the appropriate channel’s free buffer value for each buffer used. When the host reclaims the frame buffers, the host should write the channel free buffer register with the number of reclaimed buffers (write to increment). There are a maximum of 65,535 free buffers available. RX*n*FREEBUFFER only needs to be updated by the host if receive QOS or flow control is used.

32.2.11.6 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the receive teardown register (RXTEARDOWN). When a teardown command is issued to an enabled receive channel, the following occurs:

- Any current frame in reception completes normally.
- The TDOWNCMPLT flag is set in the next buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A receive interrupt for the channel is issued to the host.
- The corresponding receive channel *n* completion pointer register (RX*n*CP) contains the value FFFF FFCh.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to RX*n*CP (note that there is no buffer descriptor in this case). Software may read RX*n*CP to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

Copyright © 2018, Texas Instruments Incorporated

32.2.11.7 Receive Frame Classification

Received frames are proper (good) frames, if they are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length (inclusive) and contain no code, align, or CRC errors.

Received frames are long frames, if their frame count exceeds the value in RXMAXLEN. The RXMAXLEN reset (default) value is 5EEh (1518 in decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames; long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames, if their frame count is less than 64 bytes. Short frames that address match and contain no errors are undersized frames; short frames with CRC, code, or alignment errors are fragment frames. If the frame length is less than or equal to 20, then the frame CRC is passed, regardless of whether the RXPASSCRC bit is set or cleared in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

A received long packet always contains RXMAXLEN number of bytes transferred to memory (if the RXCEFEN bit is set in RXMBPENABLE), regardless of the value of the RXPASSCRC bit. Following is an example with RXMAXLEN set to 1518:

- If the frame length is 1518, then the packet is not a long packet and there are 1514 or 1518 bytes transferred to memory depending on the value of the RXPASSCRC bit.
- If the frame length is 1519, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last three bytes are the first three CRC bytes.
- If the frame length is 1520, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last two bytes are the first two CRC bytes.
- If the frame length is 1521, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last byte is the first CRC byte.
- If the frame length is 1522, there are 1518 bytes transferred to memory. The last byte is the last data byte.

32.2.11.8 Promiscuous Receive Mode

When the promiscuous receive mode is enabled by setting the RXCAFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE), nonaddress matching frames that would normally be filtered are transferred to the promiscuous channel. Address matching frames that would normally be filtered due to errors are transferred to the address match channel when the RXCAFEN and RXCEFEN bits in RXMBPENABLE are set. A frame is considered to be an address matching frame only if it is enabled to be received on a unicast, multicast, or broadcast channel. Frames received to disabled unicast, multicast, or broadcast channels are considered nonaddress matching.

MAC control frames address match only if the RXCMFEN bit in RXMBPENABLE is set. The RXCEFEN and RXCSFEN bits in RXMBPENABLE determine whether error frames are transferred to memory or not, but they do not determine whether error frames are address matching or not. Short frames are a special type of error frames.

A single channel is selected as the promiscuous channel by the RXPROMCH bit in RXMBPENABLE. The promiscuous receive mode is enabled by the RXCMFEN, RXCEFEN, RXCSFEN, and RXCAFEN bits in RXMBPENABLE. Table 32-7 shows the effects of the promiscuous enable bits. Proper frames are frames that are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length inclusive and contain no code, align, or CRC errors.

Copyright © 2018, Texas Instruments Incorporated

Table 32-7. Receive Frame Treatment Summary

Address Match	RXCAFEN	RXCEFEN	RXCMFEN	RXCSFEN	Receive Frame Treatment
0	0	X	X	X	No frames transferred.
0	1	0	0	0	Proper frames transferred to promiscuous channel.
0	1	0	0	1	Proper/undersized data frames transferred to promiscuous channel.
0	1	0	1	0	Proper data and control frames transferred to promiscuous channel.
0	1	0	1	1	Proper/undersized data and control frames transferred to promiscuous channel.
0	1	1	0	0	Proper/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control or undersized/fragment frames are transferred.
0	1	1	0	1	Proper/undersized/fragment/oversize/jabber/code/ align/CRC data frames transferred to promiscuous channel. No control frames are transferred.
0	1	1	1	0	Proper/oversize/jabber/code/align/CRC data and control frames transferred to promiscuous channel. No undersized frames are transferred.
0	1	1	1	1	All nonaddress matching frames with and without errors transferred to promiscuous channel.
1	X	0	0	0	Proper data frames transferred to address match channel.
1	X	0	0	1	Proper/undersized data frames transferred to address match channel.
1	X	0	1	0	Proper data and control frames transferred to address match channel.
1	X	0	1	1	Proper/undersized data and control frames transferred to address match channel.
1	X	1	0	0	Proper/oversize/jabber/code/align/CRC data frames transferred to address match channel. No control or undersized frames are transferred.
1	X	1	0	1	Proper/oversize/jabber/fragment/undersized/code/ align/CRC data frames transferred to address match channel. No control frames are transferred.
1	X	1	1	0	Proper/oversize/jabber/code/align/CRC data and control frames transferred to address match channel. No undersized/fragment frames are transferred.
1	X	1	1	1	All address matching frames with and without errors transferred to the address match channel

Copyright © 2018, Texas Instruments Incorporated

32.2.11.9 Receive Overrun

The types of receive overrun are:

- FIFO start of frame overrun (FIFO_SOF)
- FIFO middle of frame overrun (FIFO_MOF)
- DMA start of frame overrun (DMA_SOF)
- DMA middle of frame overrun (DMA_MOF)

The statistics counters used to track these types of receive overrun are:

- Receive start of frame overruns register (RXSOFOVERRUNS)
- Receive middle of frame overruns register (RXMOFOVERRUNS)
- Receive DMA overruns register (RXDMAOVERRUNS)

Start of frame overruns happen when there are no resources available when frame reception begins. Start of frame overruns increment the appropriate overrun statistic(s) and the frame is filtered.

Middle of frame overruns happen when there are some resources to start the frame reception, but the resources run out during frame reception. In normal operation, a frame that overruns after starting the frame reception is filtered and the appropriate statistic(s) are incremented; however, the RXCEFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) affects overrun frame treatment. Table 32-8 shows how the overrun condition is handled for the middle of frame overrun.

Table 32-8. Middle of Frame Overrun Treatment

Address Match	RXCAFEN	RXCEFEN	Middle of Frame Overrun Treatment
0	0	X	Overrun frame filtered.
0	1	0	Overrun frame filtered.
0	1	1	As much frame data as possible is transferred to the promiscuous channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN and NOMATCH flags are set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated and be a jabber or oversize).
1	X	0	Overrun frame filtered with the appropriate overrun statistic(s) incremented.
1	X	1	As much frame data as possible is transferred to the address match channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN flag is set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated).

Copyright © 2018, Texas Instruments Incorporated

32.2.12 Packet Transmit Operation

The transmit DMA is an eight channel interface. Priority between the eight queues may be either fixed or round-robin as selected by the TXPTYPE bit in the MAC control register (MACCONTROL). If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round-robin priority proceeds from channel 0 to channel 7.

32.2.12.1 Transmit DMA Host Configuration

To configure the transmit DMA for operation the host must perform:

- Write the MAC source address low bytes register (MACSRCADDRLO) and the MAC source address high bytes register (MACSRCADDRHI) (used for pause frames on transmit).
- Initialize the transmit channel *n* DMA head descriptor pointer registers (TX*n*HDP) to 0.
- Enable the desired transmit interrupts using the transmit interrupt mask set register (TXINTMASKSET) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Setup the transmit channel(s) buffer descriptors in host memory.
- Enable the transmit DMA controller by setting the TXEN bit in the transmit control register (TXCONTROL).
- Write the appropriate TX*n*HDP with the pointer to the first descriptor to start transmit operations.

32.2.12.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the transmit teardown register (TXTEARDOWN). When a teardown command is issued to an enabled transmit channel, the following occurs:

- Any frame currently in transmission completes normally.
- The TDOWNCMPLT flag is set in the next SOP buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A transmit interrupt is issued to inform the host of the channel teardown.
- The corresponding transmit channel *n* completion pointer register (TX*n*CP) contains the value FFFF FFFCh.
- The host should acknowledge a teardown interrupt with an FFFF FFFCh acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to TX*n*CP (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location (TX*n*CP) to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

Copyright © 2018, Texas Instruments Incorporated

32.2.13 Receive and Transmit Latency

The transmit and receive FIFOs each contain three 64-byte cells. The EMAC begins transmission of a packet on the wire after TXCELLTHRESH (configurable through the FIFO control register) cells, or a complete packet, are available in the FIFO.

Transmit underrun cannot occur for packet sizes of TXCELLTHRESH times 64 bytes (or less). For larger packet sizes, transmit underrun occurs if the memory latency is greater than the time required to transmit a 64-byte cell on the wire; this is 5.12 μs in 100 Mbps mode and 51.2 μs in 10 Mbps mode. The memory latency time includes all buffer descriptor reads for the entire cell data.

Receive overrun is prevented if the receive memory cell latency is less than the time required to transmit a 64-byte cell on the wire: 5.12 μs in 100 Mbps mode, or 51.2 μs in 10 Mbps mode. The latency time includes any required buffer descriptor reads for the cell data.

Latency to system's internal and external RAM can be controlled through the use of the transfer node priority allocation register available at the device level. Latency to descriptor RAM is low because RAM is local to the EMAC, as it is part of the EMAC control module.

32.2.14 Transfer Node Priority

The device contains a chip-level master priority register that is used to set the priority of the transfer node used in issuing memory transfer requests to system memory.

Although the EMAC has internal FIFOs to help alleviate memory transfer arbitration problems, the average transfer rate of data read and written by the EMAC to internal or external processor memory must be at least that of the Ethernet wire rate. In addition, the internal FIFO system can not withstand a single memory latency event greater than the time it takes to fill or empty a TXCELLTHRESH number of internal 64 byte FIFO cells.

For 100 Mbps operation, these restrictions translate into the following rules:

- The short-term average, each 64-byte memory read/write request from the EMAC must be serviced in no more than 5.12 μs.
- Any single latency event in request servicing can be no longer than (5.12 × TXCELLTHRESH) μs.

32.2.15 Reset Considerations

32.2.15.1 Software Reset Considerations

The peripheral clock is controlled by the Global Clock Module (GCM), while the reset to the EMAC, MDIO and EMAC control module is controlled by the system module. See the "Architecture" chapter of the Technical Reference Manual for more on how to enable or disable the peripheral clock to the EMAC, MDIO and EMAC control module. For more on how the EMAC, MDIO, and EMAC control module are disabled or placed in reset at runtime, see Section 32.2.18.

Within the peripheral itself, the EMAC component of the Ethernet MAC peripheral can be placed in a reset state by writing to the soft reset register (SOFTRESET). Writing a 1 to the SOFTRESET bit causes the EMAC logic to be reset and the register values to be set to their default values. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the configuration bus; it is the responsibility of the software to verify that there are no pending frames to be transferred. After writing a 1 to the SOFTRESET bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred; if a 0 is read, then a reset has occurred.

After a software reset operation, all the EMAC registers need to be reinitialized for proper data transmission, including the FULLDUPLEX bit setting in the MAC control register (MACCONTROL).

Unlike the EMAC module, the MDIO and EMAC control modules cannot be placed in reset from a register inside their memory map.

32.2.15.2 Hardware Reset Considerations

When a hardware reset occurs, the EMAC peripheral has its register values reset and all the components return to their default state. After the hardware reset, the EMAC needs to be initialized before being able to resume its data transmission, as described in Section 32.2.16.

A hardware reset is the only means of recovering from the error interrupts (HOSTPEND), which are triggered by errors in packet buffer descriptors. Before doing a hardware reset, you should inspect the error codes in the MAC status register (MACSTATUS) that gives information about the type of software error that needs to be corrected. For detailed information on error interrupts, see Section 32.2.17.1.4.

Copyright © 2018, Texas Instruments Incorporated

32.2.16 Initialization

32.2.16.1 Enabling the EMAC/MDIO Peripheral

When the device is powered on, the EMAC peripheral becomes enabled as soon as the system reset is released, and the EMAC peripheral registers are set to their default values. The application software can configure the EMAC peripheral registers as required.

32.2.16.2 EMAC Control Module Initialization

The EMAC control module is used for global interrupt enables and to pace interrupts using 1ms time windows. There is also an 8K block of CPPI RAM local to the EMAC that is used to hold packet buffer descriptors.

Note that although the EMAC control module and the EMAC module have slightly different functions, in practice, the type of maintenance performed on the EMAC control module is more commonly conducted from the EMAC module software (as opposed to the MDIO module).

The initialization of the EMAC control module consists of two parts:

1. Configuration of the interrupt to the CPU.
2. Initialization of the EMAC control module:
   - Setting the interrupt pace counts using the EMAC control module registers INTCONTROL, C0RXIMAX, and C0TXIMAX
   - Initializing the EMAC and MDIO modules
   - Enabling interrupts in the EMAC control module using the EMAC control module interrupt control registers C0RXTHRESHEN, C0RXEN, C0TXEN, and C0MISCEN.

The process of mapping the EMAC interrupts to the CPU is done through the Vectored Interrupt Manager (VIM). Once the interrupt is mapped to a CPU interrupt, general masking and unmasking of interrupts (to control reentrancy) should be done at the chip level by manipulating the interrupt core enable mask registers.

32.2.16.3 MDIO Module Initialization

The MDIO module is used to initially configure and monitor one or more external PHY devices. Other than initializing the software state machine (details on this state machine can be found in the IEEE 802.3 standard), all that needs to be done for the MDIO module is to enable the MDIO engine and to configure the clock divider. To set the clock divider, supply an MDIO clock of 1 MHz. For example, if the peripheral clock is 50 MHz, the divider can be set to 50.

Both the state machine enable and the MDIO clock divider are controlled through the MDIO control register (CONTROL). If none of the potentially connected PHYs require the access preamble, the PREAMBLE bit in CONTROL can also be set to speed up PHY register access.

If the MDIO module is to operate on an interrupt basis, the interrupts can be enabled at this time using the MDIO user command complete interrupt mask set register (USERINTMASKSET) for register access and the MDIO user PHY select register (USERPHYSEL*n*) if a target PHY is already known.

Once the MDIO state machine has been initialized and enabled, it starts polling all 32 PHY addresses on the MDIO bus, looking for an active PHY. Since it can take up to 50 μs to read one register, it can be some time before the MDIO module provides an accurate representation of whether a PHY is available. Also, a PHY can take up to 3 seconds to negotiate a link. Thus, it is advisable to run the MDIO software off a time-based event rather than polling.

For more information on PHY control registers, see your PHY device documentation.

32.2.16.4 EMAC Module Initialization

The EMAC module is used to send and receive data packets over the network. This is done by maintaining up to eight transmit and receive descriptor queues. The EMAC module configuration must also be kept up-to-date based on PHY negotiation results returned from the MDIO module. Most of the work in developing an application or device driver for Ethernet is programming this module.

The following is the initialization procedure a device driver would follow to get the EMAC to the state where it is ready to receive and send Ethernet packets. Some of these steps are not necessary when performed immediately after device reset.

1. If enabled, clear the device interrupt enable bits in the EMAC control module interrupt control registers C0RXTHRESHEN, C0RXEN, C0TXEN, and C0MISCEN.
2. Clear the MAC control register (MACCONTROL), receive control register (RXCONTROL), and transmit control register (TXCONTROL) (not necessary immediately after reset).
3. Initialize all 16 header descriptor pointer registers (RX*n*HDP and TX*n*HDP) to 0.
4. Clear all 36 statistics registers by writing 0 (not necessary immediately after reset).
5. Setup the local Ethernet MAC address by programming the MAC index register (MACINDEX), MAC address high bytes register (MACADDRHI), and MAC address low bytes register (MACADDRLO). Be sure to program all eight MAC address registers - whether the receive channel is to be enabled or not. Duplicate the same MAC address across all unused channels. When using more than one receive channel, start with channel 0 and progress upwards.
6. If buffer flow control is to be enabled, initialize the receive channel *n* free buffer count registers (RX*n*FREEBUFFER), receive channel *n* flow control threshold register (RX*n*FLOWTHRESH), and receive filter low priority frame threshold register (RXFILTERLOWTHRESH).
7. Most device drivers open with no multicast addresses, so clear the MAC address hash registers (MACHASH1 and MACHASH2) to 0.
8. Write the receive buffer offset register (RXBUFFEROFFSET) value (typically 0).
9. Initially clear all unicast channels by writing FFh to the receive unicast clear register (RXUNICASTCLEAR). If unicast is desired, it can be enabled now by writing the receive unicast set register (RXUNICASTSET). Some drivers will default to unicast on device open while others will not.
10. Setup the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) with an initial configuration. The configuration is based on the current receive filter settings of the device driver. Some drivers may enable things like broadcast and multicast packets immediately, while others may not.
11. Set the appropriate configuration bits in MACCONTROL (do not set the GMIIEN bit yet).
12. Clear all unused channel interrupt bits by writing the receive interrupt mask clear register (RXINTMASKCLEAR) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
13. Enable the receive and transmit channel interrupt bits in the receive interrupt mask set register (RXINTMASKSET) and the transmit interrupt mask set register (TXINTMASKSET) for the channels to be used, and enable the HOSTMASK and STATMASK bits using the MAC interrupt mask set register (MACINTMASKSET).
14. Initialize the receive and transmit descriptor list queues.
15. Prepare receive by writing a pointer to the head of the receive buffer descriptor list to RX*n*HDP.
16. Enable the receive and transmit DMA controllers by setting the RXEN bit in RXCONTROL and the TXEN bit in TXCONTROL. Then set the GMIIEN bit in MACCONTROL.
17. Enable the device interrupt in EMAC control module registers C0RXTHRESHEN, C0RXEN, C0TXEN, and C0MISCEN.

32.2.17 Interrupt Support

32.2.17.1 EMAC Module Interrupt Events and Requests

The EMAC module generates 26 interrupt events:

- TXPEND*n*: Transmit packet completion interrupt for transmit channels 0 through 7
- RXPEND*n*: Receive packet completion interrupt for receive channels 0 through 7
- RXTHRESHPEND*n*: Receive packet completion interrupt for receive channels 0 through 7 when flow control is enabled and the number of free buffers is below the threshold
- STATPEND: Statistics interrupt
- HOSTPEND: Host error interrupt

32.2.17.1.1 Transmit Packet Completion Interrupts

The transmit DMA engine has eight channels, with each channel having a corresponding interrupt (TXPEND*n*). The transmit interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight transmit channel interrupts may be individually enabled by setting the appropriate bit in the transmit interrupt mask set register (TXINTMASKSET) to 1. Each of the eight transmit channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 to the transmit interrupt mask clear register (TXINTMASKCLEAR). The raw and masked transmit interrupt status may be read by reading the transmit interrupt status (unmasked) register (TXINTSTATRAW) and the transmit interrupt status (masked) register (TXINTSTATMASKED), respectively.

When the EMAC completes the transmission of a packet, the EMAC issues an interrupt to the CPU (via the EMAC control module) when it writes the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges an interrupt by writing the address of the last buffer descriptor processed to the queue's associated transmit completion pointer in the transmit DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC port (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has transmitted more packets than the CPU has processed interrupts for), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has transferred), the pending interrupt is cleared. The value that the EMAC is expecting is found by reading the transmit channel *n* completion pointer register (TX*n*CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC control module after processing packets by writing the appropriate C0RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See Section 32.5.12 for the acknowledge key values.

32.2.17.1.2 Receive Packet Completion Interrupts

The receive DMA engine has eight channels, which each channel having a corresponding interrupt (RXPEND*n*). The receive interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight receive channel interrupts may be individually enabled by setting the appropriate bit in the receive interrupt mask set register (RXINTMASKSET) to 1. Each of the eight receive channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively.

Copyright © 2018, Texas Instruments Incorporated

When the EMAC completes a packet reception, the EMAC issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer in the receive DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has received more packets than the CPU has processed interrupts for), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has received), the pending interrupt is de-asserted. The value that the EMAC is expecting is found by reading the receive channel *n* completion pointer register (RX*n*CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC control module after processing packets by writing the appropriate C0TX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See Section 32.5.12 for the acknowledge key values.

32.2.17.1.3 Statistics Interrupt

The statistics level interrupt (STATPEND) is issued when any statistics value is greater than or equal to 8000 0000h, if enabled by setting the STATMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. As long as the most-significant bit of any statistics value is set, the interrupt remains asserted.

The application software must akcnowledge the EMAC control module after receiving statistics interrupts by writing the appropriate C0MISC key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See Section 32.5.12 for the acknowledge key values.

32.2.17.1.4 Host Error Interrupt

The host error interrupt (HOSTPEND) is issued, if enabled, under error conditions dealing with the handling of buffer descriptors, detected during transmit or receive DMA transactions. The failure of the software application to supply properly formatted buffer descriptors results in this error. The error bit can only be cleared by resetting the EMAC module in hardware.

The host error interrupt is enabled by setting the HOSTMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The host error interrupt is disabled by clearing the appropriate bit by writing a 1 in the MAC interrupt mask clear register (MACINTMASKCLEAR). The raw and masked host error interrupt status may be read by reading the MAC interrupt status (unmasked) register (MACINTSTATRAW) and the MAC interrupt status (masked) register (MACINTSTATMASKED), respectively.

The transmit host error conditions are:

- SOP error
- Ownership bit not set in SOP buffer
- Zero next buffer descriptor pointer with EOP
- Zero buffer pointer
- Zero buffer length
- Packet length error

Copyright © 2018, Texas Instruments Incorporated

The receive host error conditions are:

- Ownership bit not set in input buffer
- Zero buffer pointer

The application software must acknowledge the EMAC control module after receiving host error interrupts by writing the appropriate C0MISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See Section 32.5.12 for the acknowledge key values.

32.2.17.1.5 Receive Threshold Interrupts

Each of the eight receive channels have a corresponding receive threshold interrupt (RX*n*THRESHPEND). The receive threshold interrupts are level interrupts that remain asserted until the triggering condition is cleared by the host. Each of the eight threshold interrupts may be individually enabled by setting to 1 the appropriate bit in the RXINTMASKSET register. Each of the eight channel interrupts may be individually disabled by clearing to 0 the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked interrupt receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED),respectively.

An RX*n*THRESHPEND interrupt bit is asserted when enabled and when the channel's associated free buffer count (RX*n*FREEBUFFER) is less than or equal to the channel's associated flow control threshold register (RX*n*FLOWTHRESH). The receive threshold interrupts use the same free buffer count and threshold logic as does flow control, but the interrupts are independently enabled from flow control. The threshold interrupts are intended to give the host an indication that resources are running low for a particular channel(s).

The applications software must acknowledge the EMAC control module after receiving threshold interrupts by writing the appropriate C0RXTHRESH key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See Section 32.5.12 for the acknowledge key values.

32.2.17.2 MDIO Module Interrupt Events and Requests

The MDIO module generates two interrupt events:

- LINKINT0: Serial interface link change interrupt. Indicates a change in the state of the PHY link selected by the USERPHYSEL0 register
- USERINT0: Serial interface user command event complete interrupt selected by the USERACCESS0 register

32.2.17.2.1 Link Change Interrupt

The MDIO module asserts a link change interrupt (LINKINT0) if there is a change in the link state of the PHY corresponding to the address in the PHYADRMON bit in the MDIO register USERPHYSEL0, and if the LINKINTENB bit is also set in USERPHYSEL0. This interrupt event is also captured in the LINKINTRAW bit in the MDIO link status change interrupt register (LINKINTRAW). LINKINTRAW bits 0 and 1 correspond to USERPHYSEL0 and USERPHYSEL1, respectively.

When the interrupt is enabled and generated, the corresponding LINKINTMASKED bit is also set in the MDIO link status change interrupt register (LINKINTMASKED). The interrupt is cleared by writing back the same bit to LINKINTMASKED (write to clear).

The application software must acknowledge the EMAC control module after receiving MDIO interrupts by writing the appropriate C0MISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See Section 32.5.12 for the acknowledge key values.

Copyright © 2018, Texas Instruments Incorporated

32.2.17.2.2 User Access Completion Interrupt

When the GO bit in one of the MDIO register USERACCESS0 transitions from 1 to 0 (indicating completion of a user access) and the corresponding USERINTMASKSET bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) corresponding to USERACCESS0 is set, a user access completion interrupt (USERINT) is asserted. This interrupt event is also captured in the USERINTRAW bit in the MDIO user command complete interrupt register (USERINTRAW). USERINTRAW bits 0 and bit 1 correspond to USERACCESS0 and USERACCESS1, respectively.

When the interrupt is enabled and generated, the corresponding USERINTMASKED bit is also set in the MDIO user command complete interrupt register (USERINTMASKED). The interrupt is cleared by writing back the same bit to USERINTMASKED (write to clear).

The application software must acknowledge the EMAC control module after receiving MDIO interrupts by writing the appropriate C0MISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See Section 32.5.12 for the acknowledge key values.

32.2.17.3 Proper Interrupt Processing

All the interrupts signaled from the EMAC and MDIO modules are level driven, so if they remain active, their level remains constant; the CPU core may require edge- or pulse-triggered interrupts. In order to properly convert the level-driven interrupt signal to an edge- or pulse-triggered signal, the application software must make use of the interrupt control logic contained in the EMAC control module.

Section 32.2.7.2 discusses the interrupt control contained in the EMAC control module. For safe interrupt processing, upon entry to the ISR, the software application should disable interrupts using the EMAC control module registers C0RXTHRESHEN, C0RXEN, C0TXEN, C0MISCEN, and then reenable them upon leaving the ISR. If any interrupt signals are active at that time, this creates another rising edge on the interrupt signal going to the CPU interrupt controller, thus triggering another interrupt. The EMAC control module also uses the EMAC control module registers INTCONTROL, C0TXIMAX, and C0RXIMAX to implement interrupt pacing. The application software must acknowledge the EMAC control module by writing the appropriate key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See Section 32.5.12 for the acknowledge key values.

32.2.17.4 Interrupt Multiplexing

The EMAC control module combines different interrupt signals from both the EMAC and MDIO modules into four interrupt signals (C0RXTHRESHPULSE, C0RXPULSE, C0TXPULSE, C0MISCPULSE) that are routed to the Vectored Interrupt Manager (VIM). The VIM is capable of relaying all four interrupt signals to the CPU.

When an interrupt is generated, the reason for the interrupt can be read from the MAC input vector register (MACINVECTOR) located in the EMAC memory map. MACINVECTOR combines the status of the following 28 interrupt signals: TXPEND*n*, RXPEND*n*, RXTHRESHPEND*n*, STATPEND, HOSTPEND, LINKINT0, and USERINT0.

For more details on the interrupt mapping, see your device-specific datasheet and VIM chapter of the Technical Reference Manual.

Copyright © 2018, Texas Instruments Incorporated

32.2.18 Power Management

Each of the three main components of the EMAC peripheral can be placed in a reduced-power mode to conserve power during periods of low activity. The peripheral clock to the EMAC peripheral is controlled by the processor Global Clock Module (GCM). The GCM allows the application to enable or disable the peripheral clock to the EMAC peripheral.

The power conservation modes available for each of the three components of the EMAC/MDIO peripheral are:

- *Idle/Disabled state*. This mode stops the clocks going to the peripheral, and prevents all the register accesses. After reenabling the peripheral from this idle state, all the registers values prior to setting into the disabled state are restored, and data transmission can proceed. No reinitialization is required.
- *System reset.* The EMAC peripheral is reset by the system reset signal output from the System module. Refer to the "Architecture" chapter of the Technical Reference Manual to identify the causes of a system reset. Upon a system reset, the registers are reset to their default value. When powering-up after a system reset, all the EMAC submodules need to be reinitialized before any data transmission can happen.

For more information on the use of the GCM, see your device-specific Technical Reference Manual.

32.2.19 Emulation Considerations

EMAC emulation control is implemented for compatibility with other peripherals. The SOFT and FREE bits in the emulation control register (EMCONTROL) allow EMAC operation to be suspended.

When the emulation suspend state is entered, the EMAC stops processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission is completed normally without suspension. For transmission, any complete or partial frame in the transmit cell FIFO is transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics are kept for ignored frames.

Table 32-9 shows how the SOFT and FREE bits affect the operation of the emulation suspend.

NOTE: Emulation suspend has not been tested.

Table 32-9. Emulation Control

CLKDIV
R/W-FFh

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -*n* = value after reset

Table 32-26. MDIO Control Register (CONTROL) Field Descriptions

Bit	Field	Value	Description
31	IDLE		State machine IDLE status bit.
		0	State machine is not in idle state.
		1	State machine is in idle state.
30	ENABLE		State machine enable control bit. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit.
		0	Disables the MDIO state machine.
		1	Enable the MDIO state machine.
29	Reserved	0	Reserved
28-24	HIGHEST_USER_CHANNEL	0-1Fh	Highest user channel that is available in the module. It is currently set to 1. This implies that MDIOUserAccess1 is the highest available user access channel.
23-21	Reserved	0	Reserved
20	PREAMBLE		Preamble disable.
		0	Standard MDIO preamble is used.
		1	Disables this device from sending MDIO frame preambles.
19	FAULT		Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to this bit clears this bit, writing a 0 has no effect.
		0	No failure.
		1	Physical layer fault; the MDIO state machine is reset.
18	FAULTENB		Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection.
		0	Disables the physical layer fault detection.
		1	Enables the physical layer fault detection.
17-16	Reserved	0	Reserved
15-0	CLKDIV	0-FFFFh	Clock Divider bits. This field specifies the division ratio between the peripheral clock and the frequency of MDIO_CLK. MDIO_CLK is disabled when CLKDIV is cleared to 0. MDIO_CLK frequency = peripheral clock frequency/(CLKDIV + 1).

32.4.3 PHY Acknowledge Status Register (ALIVE)

The PHY acknowledge status register (ALIVE) is shown in Figure 32-30 and described in Table 32-27.

Figure 32-30. PHY Acknowledge Status Register (ALIVE) (offset = 08h)

31	0
ALIVE	
R/W1C-0	

LEGEND: R/W = Read/Write; W1C = Write 1 to clear (writing a 0 has no effect); -*n* = value after reset

Table 32-27. PHY Acknowledge Status Register (ALIVE) Field Descriptions

Bit	Field	Value	Description
31-0	ALIVE		MDIO Alive bits. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY; the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect.
		0	The PHY fails to acknowledge the access.
		1	The most recent access to the PHY with an address corresponding to the register bit number was acknowledged by the PHY.

32.4.4 PHY Link Status Register (LINK)

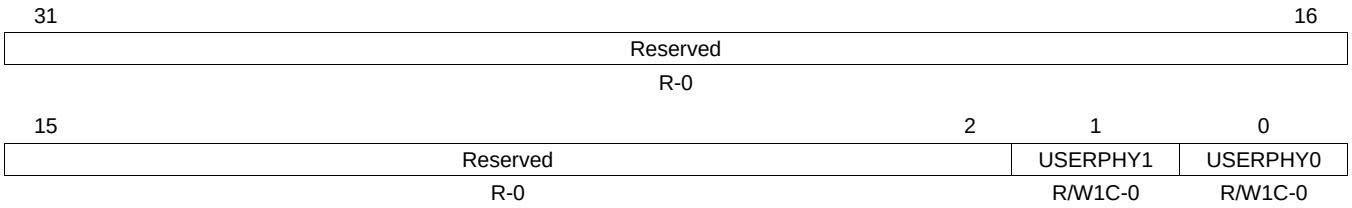
The PHY link status register (LINK) is shown in Figure 32-31 and described in Table 32-28.

Figure 32-31. PHY Link Status Register (LINK) (offset = 0Ch)

31	0
LINK	
R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 32-28. PHY Link Status Register (LINK) Field Descriptions



Bit	Field	Value	Description
31-0	LINK		MDIO Link state bits. This register is updated after a read of the generic status register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect.
		0	The PHY indicates it does not have a link or fails to acknowledge the read transaction.
		1	The PHY with the corresponding address has a link and the PHY acknowledges the read transaction.

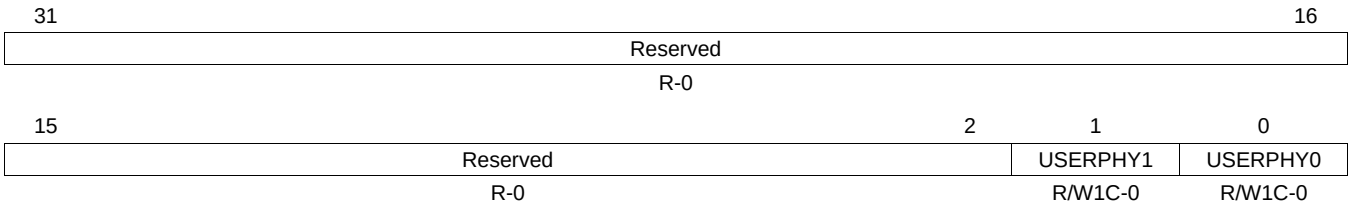
32.4.5 MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)

The MDIO link status change interrupt (unmasked) register (LINKINTRAW) is shown in Figure 32-32 and described in Table 32-29.

Figure 32-32. MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW) (offset = 10h)

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -*n* = value after reset

Table 32-29. MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW) Field Descriptions



Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	USERPHY1		MDIO Link change event, raw value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL1. Writing a 1 will clear the event, writing a 0 has no effect.
		0	No MDIO link change event.
		1	An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL1.
0	USERPHY0		MDIO Link change event, raw value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL0. Writing a 1 will clear the event, writing a 0 has no effect.
		0	No MDIO link change event.
		1	An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL0.

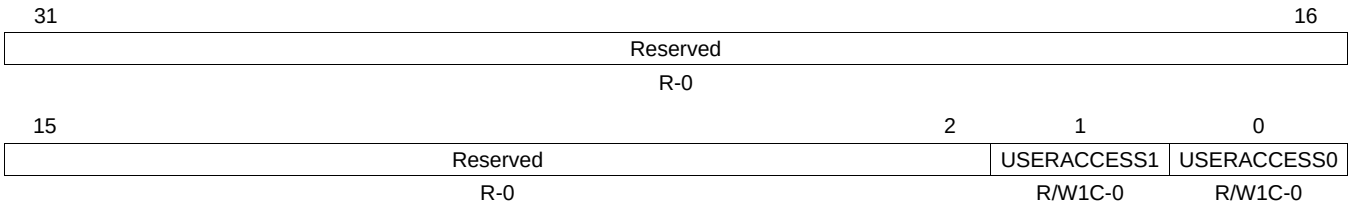
32.4.6 MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED)

The MDIO link status change interrupt (masked) register (LINKINTMASKED) is shown in Figure 32-33 and described in Table 32-30.

Figure 32-33. MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED) (offset = 14h)

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -*n* = value after reset

Table 32-30. MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED) Field Descriptions



Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	USERPHY1		MDIO Link change interrupt, masked value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL1 and the corresponding LINKINTENB bit was set. Writing a 1 will clear the event, writing a 0 has no effect.
		0	No MDIO link change event.
		1	An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL1 and the LINKINTENB bit in USERPHYSEL1 is set to 1.
0	USERPHY0		MDIO Link change interrupt, masked value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL0 and the corresponding LINKINTENB bit was set. Writing a 1 will clear the event, writing a 0 has no effect.
		0	No MDIO link change event.
		1	An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL0 and the LINKINTENB bit in USERPHYSEL0 is set to 1.

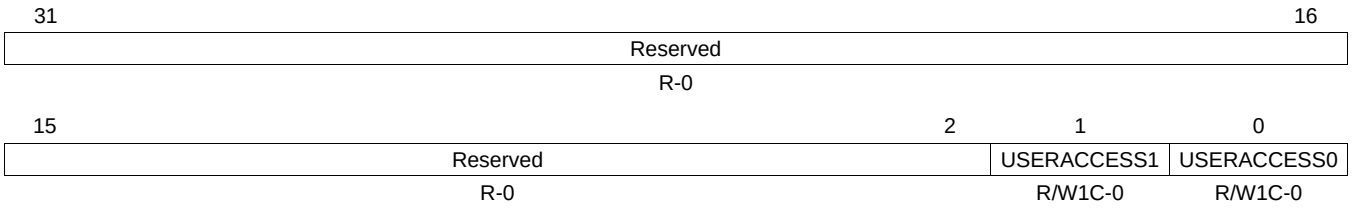
32.4.7 MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW)

The MDIO user command complete interrupt (unmasked) register (USERINTRAW) is shown in Figure 32-34 and described in Table 32-31.

Figure 32-34. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW) (offset = 20h)

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -*n* = value after reset

Table 32-31. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW) Field Descriptions



Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	USERACCESS1		MDIO User command complete event bit. When asserted, the bit indicates that the previously scheduled PHY read or write command using the USERACCESS1 register has completed. Writing a 1 will clear the event, writing a 0 has no effect.
		0	No MDIO user command complete event.
		1	The previously scheduled PHY read or write command using MDIO user access register USERACCESS1 has completed.
0	USERACCESS0		MDIO User command complete event bit. When asserted, the bit indicates that the previously scheduled PHY read or write command using the USERACCESS0 register has completed. Writing a 1 will clear the event, writing a 0 has no effect.
		0	No MDIO user command complete event.
		1	The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed.

32.4.8 MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED)

The MDIO user command complete interrupt (masked) register (USERINTMASKED) is shown in Figure 32-35 and described in Table 32-32.

Figure 32-35. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED) (offset = 24h)

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -*n* = value after reset

Table 32-32. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	USERACCESS1		Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS1 register has completed. Writing a 1 will clear the interrupt, writing a 0 has no effect.
		0	No MDIO user command complete event.
		1	The previously scheduled PHY read or write command using MDIO user access register USERACCESS1 has completed and the corresponding bit in USERINTMASKSET is set to 1.
0	USERACCESS0		Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS0 register has completed. Writing a 1 will clear the interrupt, writing a 0 has no effect.
		0	No MDIO user command complete event.
		1	The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed and the corresponding bit in USERINTMASKSET is set to 1.

R/W-0

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set (writing a 0 has no effect); -*n* = value after reset

Table 32-35. MDIO User Access Register 0 (USERACCESS0) Field Descriptions

Bit	Field	Value	Description
31	GO	0-1	Go bit. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so; this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is writeable only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to USERACCESS0 are blocked when the GO bit is 1.
30	WRITE		Write enable bit. Setting this bit to 1 causes the MDIO transaction to be a register write; otherwise, it is a register read.
		0	The user command is a read operation.
		1	The user command is a write operation.
29	ACK	0-1	Acknowledge bit. This bit is set if the PHY acknowledged the read transaction.
28-26	Reserved	0	Reserved
25-21	REGADR	0-1Fh	Register address bits. This field specifies the PHY register to be accessed for this transaction.
20-16	PHYADR	0-1Fh	PHY address bits. This field specifies the PHY to be accessed for this transaction.
15-0	DATA	0-FFFFh	User data bits. These bits specify the data value read from or to be written to the specified PHY register.

Table 32-60. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved
30	RXPASSCRC		Pass receive CRC enable bit.
		0	Received CRC is discarded for all channels and is not included in the buffer descriptor packet length field.
		1	Received CRC is transferred to memory for all channels and is included in the buffer descriptor packet length.
29	RXQOSEN		Receive quality of service enable bit.
		0	Receive QOS is disabled.
		1	Receive QOS is enabled.
28	RXNOCHAIN		Receive no buffer chaining bit.
		0	Received frames can span multiple buffers.
		1	The Receive DMA controller transfers each frame into a single buffer, regardless of the frame or buffer size. All remaining frame data after the first buffer is discarded. The buffer descriptor buffer length field will contain the entire frame byte count (up to 65535 bytes).
27-25	Reserved	0	Reserved
24	RXCMFEN		Receive copy MAC control frames enable bit. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in MACCONTROL, regardless of the value of RXCMFEN. Frames transferred to memory due to RXCMFEN will have the CONTROL bit set in their EOP buffer descriptor.
		0	MAC control frames are filtered (but acted upon if enabled).
		1	MAC control frames are transferred to memory.
23	RXCSFEN		Receive copy short frames enable bit. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RXCSFEN will have the FRAGMENT or UNDERSIZE bit set in their EOP buffer descriptor. Fragments are short frames that contain CRC / align / code errors and undersized are short frames without errors.
		0	Short frames are filtered.
		1	Short frames are transferred to memory.

32.5.25 Receive Buffer Offset Register (RXBUFFEROFFSET)

The receive buffer offset register (RXBUFFEROFFSET) is shown in Figure 32-66 and described in Table 32-64.

Figure 32-66. Receive Buffer Offset Register (RXBUFFEROFFSET) (offset = 110h)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

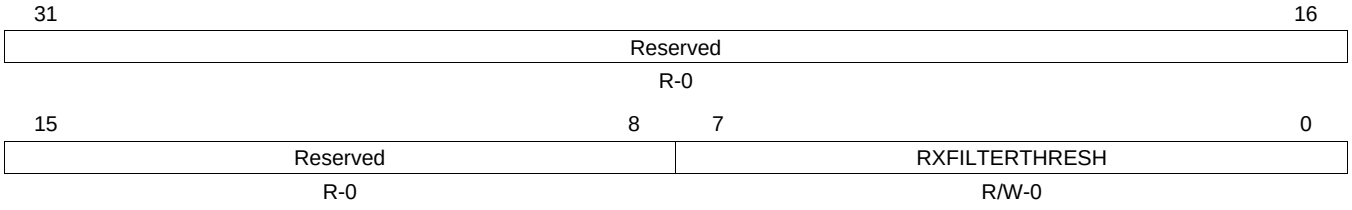

Table 32-64. Receive Buffer Offset Register (RXBUFFEROFFSET) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	RXBUFFEROFFSET	0-FFFFh	Receive buffer offset value. These bits are written by the EMAC into each frame SOP buffer descriptor Buffer Offset field. The frame data begins after the RXBUFFEROFFSET value of bytes. A value of 0 indicates that there are no unused bytes at the beginning of the data, and that valid data begins on the first byte of the buffer. A value of Fh (15) indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.

32.5.26 Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) is shown in Figure 32-67 and described in Table 32-65.

Figure 32-67. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH) (offset = 114h)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 32-65. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RXFILTERTHRESH	0-FFh	Receive filter low threshold. These bits contain the free buffer count threshold value for filtering low priority incoming frames. This field should remain 0, if no filtering is desired.

Copyright © 2018, Texas Instruments Incorporated

32.5.27 Receive Channel Flow Control Threshold Registers (RX0FLOWTHRESH-RX7FLOWTHRESH)

The receive channel 0-7 flow control threshold register (RX*n*FLOWTHRESH) is shown in Figure 32-68 and described in Table 32-66.

Figure 32-68. Receive Channel *n* Flow Control Threshold Register (RX*n*FLOWTHRESH) (offset = 120h-13Ch)

31	16
Reserved	
R-0	

15	8	7	0
Reserved		RX*n*FLOWTHRESH	
R-0		R/W-0

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RX*n*FLOWTHRESH	0-FFh	Receive flow threshold. These bits contain the threshold value for issuing flow control on incoming frames for channel *n* (when enabled).

32.5.28 Receive Channel Free Buffer Count Registers (RX0FREEBUFFER-RX7FREEBUFFER)

The receive channel 0-7 free buffer count register (RX*n*FREEBUFFER) is shown in Figure 32-69 and described in Table 32-67.

R-0	

15	0
RX*n*FREEBUF	
WI-0	

LEGEND: R = Read only; WI = Write to increment; -*n* = value after reset

Table 32-67. Receive Channel *n* Free Buffer Count Register (RX*n*FREEBUFFER) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	RX*n*FREEBUF	0-FFh	Receive free buffer count. These bits contain the count of free buffers available. The RXFILTERTHRESH value is compared with this field to determine if low priority frames should be filtered. The RX*n*FLOWTHRESH value is compared with this field to determine if receive flow control should be issued against incoming packets (if enabled). This is a write-to-increment field. This field rolls over to 0 on overflow. If hardware flow control or QOS is used, the host must initialize this field to the number of available buffers (one register per channel). The EMAC decrements the associated channel register for each received frame by the number of buffers in the received frame. The host must write this field with the number of buffers that have been freed due to host processing.

Table 32-68. MAC Control Register (MACCONTROL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	RMIISPEED		RMII interface transmit and receive speed select.
		0	Operate RMII interface in 10 Mbps speed mode.
		1	Operate RMII interface in 100 Mbps speed mode.
14	RXOFFLENBLOCK		Receive offset / length word write block.
		0	Do not block the DMA writes to the receive buffer descriptor offset / buffer length word.
		1	Block all EMAC DMA controller writes to the receive buffer descriptor offset / buffer length words during packet processing. When this bit is set, the EMAC will never write the third word to any receive buffer descriptor.
13	RXOWNERSHIP		Receive ownership write bit value.
		0	The EMAC writes the Receive ownership bit to 0 at the end of packet processing.
		1	The EMAC writes the Receive ownership bit to 1 at the end of packet processing. If you do not use the ownership mechanism, you can set this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.
12	Reserved	0	Reserved
11	CMDIDLE		Command Idle bit.
		0	Idle is not commanded.
		1	Idle is commanded (read IDLE in the MACSTATUS register).
10	TXSHORTGAPEN		Transmit Short Gap enable.
		0	Transmit with a short IPG is disabled. Normal 96-bit time IPG is inserted between packets.
		1	Transmit with a short IPG is enabled. Shorter 88-bit time IPG is inserted between packets.
9	TXPTYPE		Transmit queue priority type.
		0	The queue uses a round-robin scheme to select the next channel for transmission.
		1	The queue uses a fixed-priority (channel 7 highest priority) scheme to select the next channel for transmission.
8-7	Reserved	0	Reserved
6	TXPACE		Transmit pacing enable bit.
		0	Transmit pacing is disabled.
		1	Transmit pacing is enabled.

Copyright © 2018, Texas Instruments Incorporated

Table 32-68. MAC Control Register (MACCONTROL) Field Descriptions (continued)

Bit	Field	Value	Description
5	GMIIEN		GMII enable bit. This bit must be set before the MAC transmits or receives data in any of the supported interface modes. (for instance, MII, RMII). This bit does not select the interface mode but rather holds or releases the MAC TX and RX state machines from reset.
		0	The MAC RX and TX state machines are held in reset.
		1	The MAC RX and TX state machines are released from reset and transmit and receive are enabled.
4	TXFLOWEN		Transmit flow control enable bit. This bit determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode, regardless of this bit setting. The RXMBPENABLE bits determine whether or not received pause frames are transferred to memory.
		0	Transmit flow control is disabled. Full-duplex mode: incoming pause frames are not acted upon.
		1	Transmit flow control is enabled. Full-duplex mode: incoming pause frames are acted upon.
3	RXBUFFERFLOWEN		Receive buffer flow control enable bit.
		0	Receive flow control is disabled. Half-duplex mode: no flow control generated collisions are sent. Full-duplex mode: no outgoing pause frames are sent.
		1	Receive flow control is enabled. Half-duplex mode: collisions are initiated when receive buffer flow control is triggered. Full-duplex mode: outgoing pause frames are sent when receive flow control is triggered.
2	Reserved	0	Reserved
1	LOOPBACK		Loopback mode. The loopback mode forces internal full-duplex mode regardless of the FULLDUPLEX bit. The loopback bit should be changed only when GMIIEN bit is deasserted.
		0	Loopback mode is disabled.
		1	Loopback mode is enabled.
0	FULLDUPLEX		Full-duplex mode.
		0	Half-duplex mode is enabled.
		1	Full-duplex mode is enabled.

32.5.30 MAC Status Register (MACSTATUS)

The MAC status register (MACSTATUS) is shown in Figure 32-71 and described in Table 32-69.

Figure 32-71. MAC Status Register (MACSTATUS) (offset = 164h)

31	30–24	23–20	19	18–16
IDLE	Reserved	TXERRCODE	Rsvd	TXERRCH
R-0	R-0	R-0	R-0	R-0

15–12	11	10–8
RXERRCODE	Reserved	RXERRCH
R-0	R-0	R-0

7–3	2	1	0
Reserved	RXQOSACT	RXFLOWACT	TXFLOWACT
R-0	R-0	R-0	R-0

LEGEND: R = Read only; -*n* = value after reset

Table 32-69. MAC Status Register (MACSTATUS) Field Descriptions

Bit	Field	Value	Description
31	IDLE		EMAC idle bit. This bit is cleared to 0 at reset; one clock after reset, it goes to 1.
		0	The EMAC is not idle.
		1	The EMAC is in the idle state.
30-24	Reserved	0	Reserved
23-20	TXERRCODE		Transmit host error code. These bits indicate that EMAC detected transmit DMA related host errors. The host should read this field after a host error interrupt (HOSTPEND) to determine the error. Host error interrupts require hardware reset in order to recover. A 0 packet length is an error, but it is not detected.
		0	No error.
		1h	SOP error; the buffer is the first buffer in a packet, but the SOP bit is not set in software.
		2h	Ownership bit not set in SOP buffer.
		3h	Zero next buffer descriptor pointer without EOP.
		4h	Zero buffer pointer.
		5h	Zero buffer length.
		6h	Packet length error (sum of buffers is less than packet length).
		7h-Fh	Reserved
19	Reserved	0	Reserved
18-16	TXERRCH		Transmit host error channel. These bits indicate which transmit channel the host error occurred on. This field is cleared to 0 on a host read.
		0	The host error occurred on transmit channel 0.
		1h	The host error occurred on transmit channel 1.
		2h	The host error occurred on transmit channel 2.
		3h	The host error occurred on transmit channel 3.
		4h	The host error occurred on transmit channel 4.
		5h	The host error occurred on transmit channel 5.
		6h	The host error occurred on transmit channel 6.
		7h	The host error occurred on transmit channel 7.

Table 32-69. MAC Status Register (MACSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
15-12	RXERRCODE		Receive host error code. These bits indicate that EMAC detected receive DMA related host errors. The host should read this field after a host error interrupt (HOSTPEND) to determine the error. Host error interrupts require hardware reset in order to recover.
		0	No error.
		1h	Reserved
		2h	Ownership bit not set in SOP buffer.
		3h	Reserved
		4h	Zero buffer pointer.
		5h-Fh	Reserved
11	Reserved	0	Reserved
10-8	RXERRCH		Receive host error channel. These bits indicate which receive channel the host error occurred on. This field is cleared to 0 on a host read.
		0	The host error occurred on receive channel 0.
		1h	The host error occurred on receive channel 1.
		2h	The host error occurred on receive channel 2.
		3h	The host error occurred on receive channel 3.
		4h	The host error occurred on receive channel 4.
		5h	The host error occurred on receive channel 5.
		6h	The host error occurred on receive channel 6.
		7h	The host error occurred on receive channel 7.
7-3	Reserved	0	Reserved
2	RXQOSACT		Receive Quality of Service (QOS) active bit. When asserted, indicates that receive quality of service is enabled and that at least one channel freebuffer count (RX*n*FREEBUFFER) is less than or equal to the RXFILTERLOWTHRESH value.
		0	Receive quality of service is disabled.
		1	Receive quality of service is enabled.
1	RXFLOWACT		Receive flow control active bit. When asserted, at least one channel freebuffer count (RX*n*FREEBUFFER) is less than or equal to the channel's corresponding RX*n*FILTERTHRESH value.
		0	Receive flow control is inactive.
		1	Receive flow control is active.
0	TXFLOWACT		Transmit flow control active bit. When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted, except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete.
		0	Transmit flow control is inactive.
		1	Transmit flow control is active.

R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 32-70. Emulation Control Register (EMCONTROL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	SOFT		Emulation soft bit. This bit is used in conjunction with FREE bit to determine the emulation suspend mode. This bit has no effect if FREE = 1.
		0	Soft mode is disabled. EMAC stops immediately during emulation halt.
		1	Soft mode is enabled. During emulation halt, EMAC stops after completion of current operation.
0	FREE		Emulation free bit. This bit is used in conjunction with SOFT bit to determine the emulation suspend mode.
		0	Free-running mode is disabled. During emulation halt, SOFT bit determines operation of EMAC.
		1	Free-running mode is enabled. During emulation halt, EMAC continues to operate.

32.5.32 FIFO Control Register (FIFOCONTROL)

The FIFO control register (FIFOCONTROL) is shown in Figure 32-73 and described in Table 32-71.

Figure 32-73. FIFO Control Register (FIFOCONTROL) (offset = 16Ch)

Table 32-71. FIFO Control Register (FIFOCONTROL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	TXCELLTHRESH		Transmit FIFO cell threshold. Indicates the number of 64-byte packet cells required to be in the transmit FIFO before the packet transfer is initiated. Packets with fewer cells will be initiated when the complete packet is contained in the FIFO. The default value is 2, but 3 is also valid. 0 and 1 are not valid values.
		0-1h	Not a valid value.
		2h	Two 64-byte packet cells required to be in the transmit FIFO.
		3h	Three 64-byte packet cells required to be in the transmit FIFO.

Reserved		SOFTRESET
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 32-73. Soft Reset Register (SOFTRESET) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	SOFTRESET		Software reset. Writing a 1 to this bit causes the EMAC logic to be reset. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the Configuration bus. After writing a 1 to this bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred. If a 0 is read, then a reset has occurred.
		0	A software reset has not occurred.
		1	A software reset has occurred.

32.5.37 MAC Hash Address Register 1 (MACHASH1)

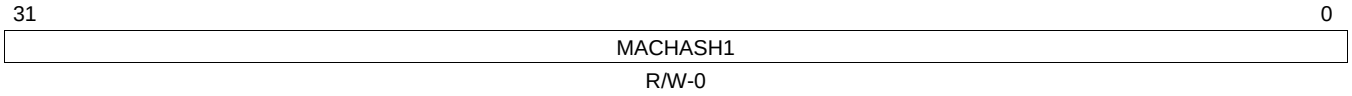
The MAC hash registers allow group addressed frames to be accepted on the basis of a hash function of the address. The hash function creates a 6-bit data value (Hash_fun) from the 48-bit destination address (DA) as follows:

```
Hash_fun(0)=DA(0) XOR DA(6) XOR DA(12) XOR DA(18) XOR DA(24) XOR DA(30) XOR DA(36) XOR DA(42);

Hash_fun(1)=DA(1) XOR DA(7) XOR DA(13) XOR DA(19) XOR DA(25) XOR DA(31) XOR DA(37) XOR DA(43);

Hash_fun(2)=DA(2) XOR DA(8) XOR DA(14) XOR DA(20) XOR DA(26) XOR DA(32) XOR DA(38) XOR DA(44);

Hash_fun(3)=DA(3) XOR DA(9) XOR DA(15) XOR DA(21) XOR DA(27) XOR DA(33) XOR DA(39) XOR DA(45);



Hash_fun(4)=DA(4) XOR DA(10) XOR DA(16) XOR DA(22) XOR DA(28) XOR DA(34) XOR DA(40) XOR DA(46);

Hash_fun(5)=DA(5) XOR DA(11) XOR DA(17) XOR DA(23) XOR DA(29) XOR DA(35) XOR DA(41) XOR DA(47);
```

This function is used as an offset into a 64-bit hash table stored in MACHASH1 and MACHASH2 that indicates whether a particular address should be accepted or not.

The MAC hash address register 1 (MACHASH1) is shown in Figure 32-78 and described in Table 32-76.

Figure 32-78. MAC Hash Address Register 1 (MACHASH1) (offset = 1D8h)

LEGEND: R/W = Read/Write; *-n* = value after reset

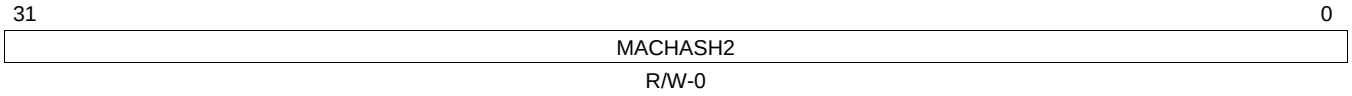


Table 32-76. MAC Hash Address Register 1 (MACHASH1) Field Descriptions

Bit	Field	Description
31-0	MACHASH1	Least-significant 32 bits of the hash table corresponding to hash values 0 to 31. If a hash table bit is set, then a group address that hashes to that bit index is accepted.

32.5.38 MAC Hash Address Register 2 (MACHASH2)

The MAC hash address register 2 (MACHASH2) is shown in Figure 32-79 and described in Table 32-77.

Figure 32-79. MAC Hash Address Register 2 (MACHASH2) (offset = 1DCh)

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 32-77. MAC Hash Address Register 2 (MACHASH2) Field Descriptions

Bit	Field	Description
31-0	MACHASH2	Most-significant 32 bits of the hash table corresponding to hash values 32 to 63. If a hash table bit is set, then a group address that hashes to that bit index is accepted.

Copyright © 2018, Texas Instruments Incorporated

32.5.39 Back Off Test Register (BOFFTEST)

The back off test register (BOFFTEST) is shown in Figure 32-80 and described in Table 32-78.

Figure 32-80. Back Off Random Number Generator Test Register (BOFFTEST) (offset = 1E0h)

31	26	25	16
Reserved		RNDNUM	
R-0		R-0	

15	12	11	10	9	0
COLLCOUNT		Reserved		TXBACKOFF	
R-0		R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 32-78. Back Off Test Register (BOFFTEST) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reserved
25-16	RNDNUM	0-3FFh	Backoff random number generator. This field allows the Backoff Random Number Generator to be read. Reading this field returns the generator's current value. The value is reset to 0 and begins counting on the clock after the deassertion of reset.
15-12	COLLCOUNT	0-Fh	Collision count. These bits indicate the number of collisions the current frame has experienced.
11-10	Reserved	0	Reserved
9-0	TXBACKOFF	0-3FFh	Backoff count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by 1 for each slot time after the collision.

32.5.40 Transmit Pacing Algorithm Test Register (TPACETEST)

The transmit pacing algorithm test register (TPACETEST) is shown in Figure 32-81 and described in Table 32-79.

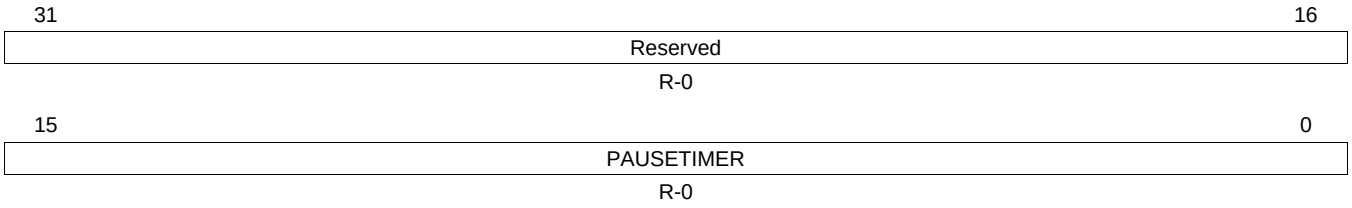
Figure 32-81. Transmit Pacing Algorithm Test Register (TPACETEST) (offset = 1E4h)

31	16
Reserved	
R-0	

15	5	4	0
Reserved		PACEVAL	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 32-79. Transmit Pacing Algorithm Test Register (TPACETEST) Field Descriptions



Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4-0	PACEVAL	0-1Fh	Pacing register current value. A nonzero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with 1Fh (31); good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to 0. When PACEVAL is nonzero, the transmitter delays four Inter Packet Gaps between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. If a transmit frame is deferred or suffers a collision, the IPG time is not stretched to four times the normal value. Transmit pacing helps reduce capture effects, which improves overall network bandwidth.

32.5.41 Receive Pause Timer Register (RXPAUSE)

The receive pause timer register (RXPAUSE) is shown in Figure 32-82 and described in Table 32-80.

Figure 32-82. Receive Pause Timer Register (RXPAUSE) (offset = 1E8h)

LEGEND: R = Read only; -*n* = value after reset

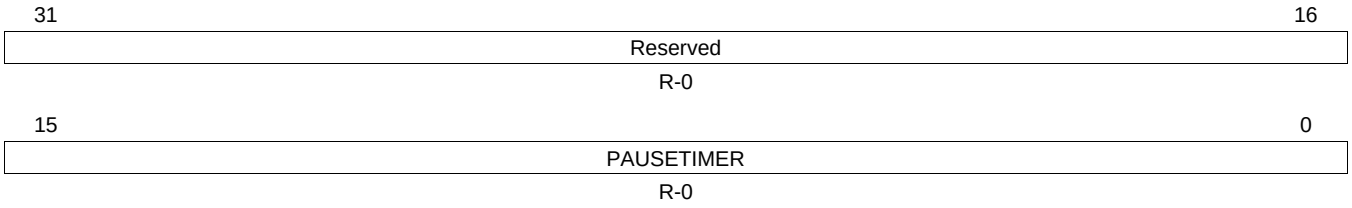

Table 32-80. Receive Pause Timer Register (RXPAUSE) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	PAUSETIMER	0-FFh	Receive pause timer value. These bits allow the contents of the receive pause timer to be observed. The receive pause timer is loaded with FF00h when the EMAC sends an outgoing pause frame (with pause time of FFFFh). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to 0, then another outgoing pause frame is sent and the load/decrement process is repeated.

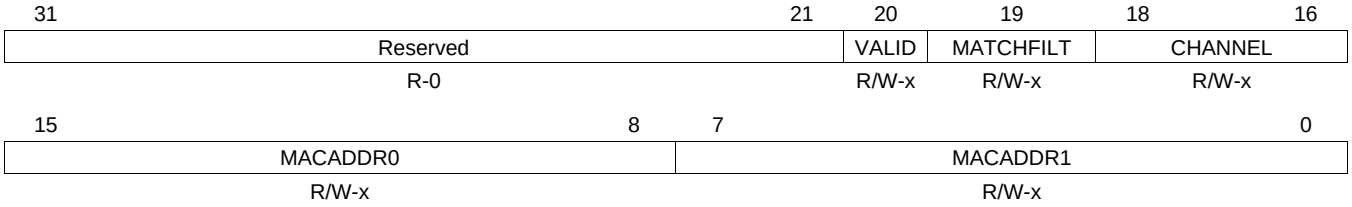
32.5.42 Transmit Pause Timer Register (TXPAUSE)

The transmit pause timer register (TXPAUSE) is shown in Figure 32-83 and described in Table 32-81.

Figure 32-83. Transmit Pause Timer Register (TXPAUSE) (offset = 1ECh)

LEGEND: R = Read only; -*n* = value after reset

Table 32-81. Transmit Pause Timer Register (TXPAUSE) Field Descriptions



Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	PAUSETIMER	0-FFh	Transmit pause timer value. These bits allow the contents of the transmit pause timer to be observed. The transmit pause timer is loaded by a received (incoming) pause frame, and then decremented at slot time intervals down to 0, at which time EMAC transmit frames are again enabled.

Copyright © 2018, Texas Instruments Incorporated

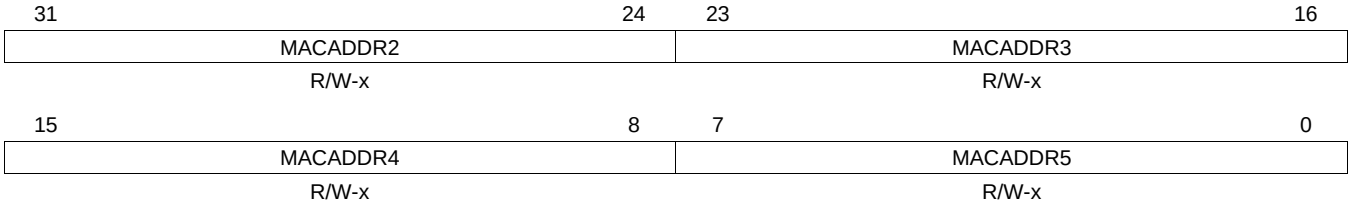
32.5.43 MAC Address Low Bytes Register (MACADDRLO)

The MAC address low bytes register used in receive address matching (MACADDRLO), is shown in Figure 32-84 and described in Table 32-82.

Figure 32-84. MAC Address Low Bytes Register (MACADDRLO) (offset = 500h)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; -x = value is indeterminate after reset

Table 32-82. MAC Address Low Bytes Register (MACADDRLO) Field Descriptions



Bit	Field	Value	Description
31-21	Reserved	0	Reserved
20	VALID		Address valid bit. This bit should be cleared to 0 for unused address channels.
		0	Address is not valid and will not be used for matching or filtering incoming packets.
		1	Address is valid and will be used for matching or filtering incoming packets.
19	MATCHFILT		Match or filter bit.
		0	The address will be used (if the VALID bit is set) to filter incoming packet addresses.
		1	The address will be used (if the VALID bit is set) to match incoming packet addresses.
18-16	CHANNEL	0-7h	Channel select. Determines which receive channel a valid address match will be transferred to. The channel is a don't care if MATCHFILT is cleared to 0.
15-8	MACADDR0	0-FFh	MAC address lower 8-0 bits (byte 0).
7-0	MACADDR1	0-FFh	MAC address bits 15-8 (byte 1).

Copyright © 2018, Texas Instruments Incorporated

32.5.44 MAC Address High Bytes Register (MACADDRHI)

The MAC address high bytes register used in receive address matching (MACADDRHI) is shown in Figure 32-85 and described in Table 32-83.

Figure 32-85. MAC Address High Bytes Register (MACADDRHI) (offset = 504h)

LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

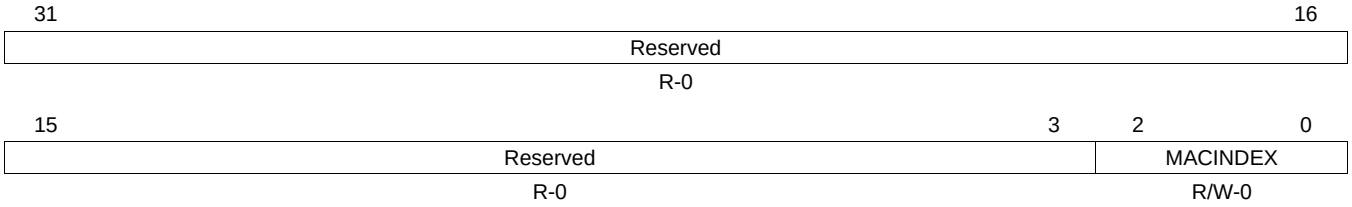


Table 32-83. MAC Address High Bytes Register (MACADDRHI) Field Descriptions

Bit	Field	Value	Description
31-24	MACADDR2	0-FFh	MAC source address bits 23-16 (byte 2).
23-16	MACADDR3	0-FFh	MAC source address bits 31-24 (byte 3).
15-8	MACADDR4	0-FFh	MAC source address bits 39-32 (byte 4).
7-0	MACADDR5	0-FFh	MAC source address bits 47-40 (byte 5). Bit 40 is the group bit. It is forced to 0 and read as 0. Therefore, only unicast addresses are represented in the address table.

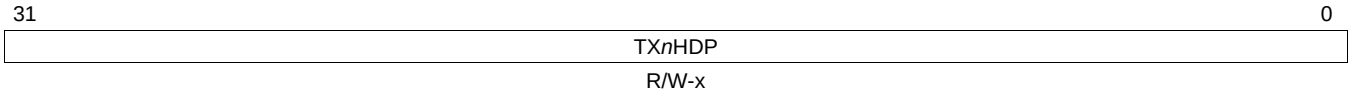
32.5.45 MAC Index Register (MACINDEX)

The MAC index register (MACINDEX) is shown in Figure 32-86 and described in Table 32-84.

Figure 32-86. MAC Index Register (MACINDEX) (offset = 508h)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 32-84. MAC Index Register (MACINDEX) Field Descriptions



Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	MACINDEX	0-7h	MAC address index. All eight addresses share the upper 40 bits. Only the lower byte is unique for each address. An address is written by first writing the address number (channel) into the MACINDEX register. The upper 32 bits of the address are then written to the MACADDRHI register, which is followed by writing the lower 16 bits of the address to the MACADDRLO register. Since all eight addresses share the upper 40 bits of the address, the MACADDRHI register only needs to be written the first time.

Copyright © 2018, Texas Instruments Incorporated

32.5.46 Transmit Channel DMA Head Descriptor Pointer Registers (TX0HDP-TX7HDP)

The transmit channel 0-7 DMA head descriptor pointer register (TX*n*HDP) is shown in Figure 32-87 and described in Table 32-85.

Figure 32-87. Transmit Channel *n* DMA Head Descriptor Pointer Register (TX*n*HDP) (offset = 600h-61Ch)

LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

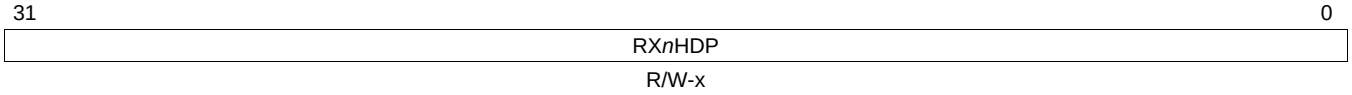


Table 32-85. Transmit Channel *n* DMA Head Descriptor Pointer Register (TX*n*HDP) Field Descriptions

Bit	Field	Description
31-0	TX*n*HDP	Transmit channel *n* DMA Head Descriptor pointer. Writing a transmit DMA buffer descriptor address to a head pointer location initiates transmit DMA operations in the queue for the selected channel. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset.

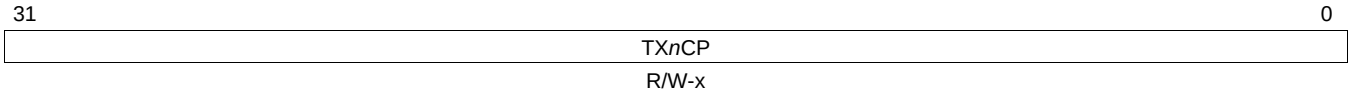
32.5.47 Receive Channel DMA Head Descriptor Pointer Registers (RX0HDP-RX7HDP)

The receive channel 0-7 DMA head descriptor pointer register (RX*n*HDP) is shown in Figure 32-88 and described in Table 32-86.

Figure 32-88. Receive Channel *n* DMA Head Descriptor Pointer Register (RX*n*HDP) (offset = 620h-63Ch)

LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

Table 32-86. Receive Channel *n* DMA Head Descriptor Pointer Register (RX*n*HDP) Field Descriptions



Bit	Field	Description
31-0	RX*n*HDP	Receive channel *n* DMA Head Descriptor pointer. Writing a receive DMA buffer descriptor address to this location allows receive DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset.

Copyright © 2018, Texas Instruments Incorporated

32.5.48 Transmit Channel Completion Pointer Registers (TX0CP-TX7CP)

The transmit channel 0-7 completion pointer register (TX*n*CP) is shown in Figure 32-89 and described in Table 32-87.

Figure 32-89. Transmit Channel *n* Completion Pointer Register (TX*n*CP) (offset = 640h-65Ch)

LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

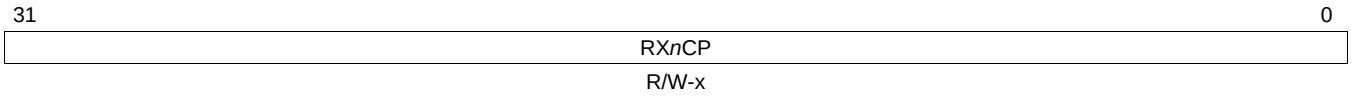


Table 32-87. Transmit Channel *n* Completion Pointer Register (TX*n*CP) Field Descriptions

Bit	Field	Description
31-0	TX*n*CP	Transmit channel *n* completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted.

32.5.49 Receive Channel Completion Pointer Registers (RX0CP-RX7CP)

The receive channel 0-7 completion pointer register (RX*n*CP) is shown in Figure 32-90 and described in Table 32-88.

Figure 32-90. Receive Channel *n* Completion Pointer Register (RX*n*CP) (offset = 660h-67Ch)

LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

Table 32-88. Receive Channel *n* Completion Pointer Register (RX*n*CP) Field Descriptions

Bit	Field	Description
31-0	RX*n*CP	Receive channel *n* completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted.

Copyright © 2018, Texas Instruments Incorporated

32.5.50 Network Statistics Registers

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to 0, 38 clocks after the rising edge of reset. When the GMIIEN bit in the MACCONTROL register is set, all statistics registers (see Figure 32-91) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMIIEN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STATPEND) is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

R/WD-0	

LEGEND: R/W = Read/Write; WD = Write to decrement; -*n* = value after reset

32.5.50.1 Good Receive Frames Register (RXGOODFRAMES) (offset = 200h)

The total number of good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

32.5.50.2 Broadcast Receive Frames Register (RXBCASTFRAMES) (offset = 204h)

The total number of good broadcast frames received on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for address FF-FF-FF-FF-FF-FFh only
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

32.5.50.3 Multicast Receive Frames Register (RXMCASTFRAMES) (offset = 208h)

The total number of good multicast frames received on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

Copyright © 2018, Texas Instruments Incorporated

32.5.50.4 Pause Receive Frames Register (RXPAUSEFRAMES) (offset = 20Ch)

The total number of IEEE 802.3X pause frames received by the EMAC (whether acted upon or not). A pause frame is defined as having all of the following:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08h and the opcode 0001h
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error
- Pause-frames had been enabled on the EMAC (TXFLOWEN bit is set in MACCONTROL).

The EMAC could have been in either half-duplex or full-duplex mode. See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

32.5.50.5 Receive CRC Errors Register (RXCRCERRORS) (offset = 210h)

The total number of frames received on the EMAC that experienced a CRC error. A frame with CRC errors is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no alignment or code error
- Had a CRC error. A CRC error is defined as having all of the following:
  - A frame containing an even number of nibbles
  - Fails the frame check sequence test

See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

32.5.50.6 Receive Alignment/Code Errors Register (RXALIGNCODEERRORS) (offset = 214h)

The total number of frames received on the EMAC that experienced an alignment error or code error. Such a frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had either an alignment error or a code error
  - An alignment error is defined as having all of the following:
    - A frame containing an odd number of nibbles
    - Fails the frame check sequence test, if the final nibble is ignored
  - A code error is defined as a frame that has been discarded because the EMACs MII_RXER pin is driven with a 1 for at least one bit-time's duration at any point during the frame's reception.

Overruns have no effect on this statistic.

CRC alignment or code errors can be calculated by summing receive alignment errors, receive code errors, and receive CRC errors.

Copyright © 2018, Texas Instruments Incorporated

32.5.50.7 Receive Oversized Frames Register (RXOVERSIZED) (offset = 218h)

The total number of oversized frames received on the EMAC. An oversized frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN in bytes
- Had no CRC error, alignment error, or code error

See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

32.5.50.8 Receive Jabber Frames Register (RXJABBER) (offset = 21Ch)

The total number of jabber frames received on the EMAC. A jabber frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN bytes long
- Had a CRC error, alignment error, or code error

See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

32.5.50.9 Receive Undersized Frames Register (RXUNDERSIZED) (offset = 220h)

The total number of undersized frames received on the EMAC. An undersized frame is defined as having all of the following:

- Was any data frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes long
- Had no CRC error, alignment error, or code error

See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

32.5.50.10 Receive Frame Fragments Register (RXFRAGMENTS) (offset = 224h)

The total number of frame fragments received on the EMAC. A frame fragment is defined as having all of the following:

- Any data frame (address matching does not matter)
- Was less than 64 bytes long
- Had a CRC error, alignment error, or code error
- Was not the result of a collision caused by half duplex, collision based flow control

See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

32.5.50.11 Filtered Receive Frames Register (RXFILTERED) (offset = 228h)

The total number of frames received on the EMAC that the EMAC address matching process indicated should be discarded. Such a frame is defined as having all of the following:

- Was any data frame (not MAC control frame) destined for any unicast, broadcast, or multicast address
- Did not experience any CRC error, alignment error, code error
- The address matching process decided that the frame should be discarded (filtered) because it did not match the unicast, broadcast, or multicast address, and it did not match due to promiscuous mode.

Copyright © 2018, Texas Instruments Incorporated

To determine the number of receive frames discarded by the EMAC for any reason, sum the following statistics (promiscuous mode disabled):

- Receive fragments
- Receive undersized frames
- Receive CRC errors
- Receive alignment/code errors
- Receive jabbers
- Receive overruns
- Receive filtered frames

This may not be an exact count because the receive overruns statistic is independent of the other statistics, so if an overrun occurs at the same time as one of the other discard reasons, then the above sum double-counts that frame.

32.5.50.12 Receive QOS Filtered Frames Register (RXQOSFILTERED) (offset = 22Ch)

The total number of frames received on the EMAC that were filtered due to receive quality of service (QOS) filtering. Such a frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- The frame destination channel flow control threshold register (RX*n*FLOWTHRESH) value was greater than or equal to the channel's corresponding free buffer register (RX*n*FREEBUFFER) value
- Was of length 64 to RXMAXLEN
- RXQOSEN bit is set in RXMBPENABLE
- Had no CRC error, alignment error, or code error

See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

32.5.50.13 Receive Octet Frames Register (RXOCTETS) (offset = 230h)

The total number of bytes in all good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See Section 32.2.6.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

32.5.50.14 Good Transmit Frames Register (TXGOODFRAMES) (offset = 234h)

The total number of good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

Copyright © 2018, Texas Instruments Incorporated

32.5.50.15 Broadcast Transmit Frames Register (TXBCASTFRAMES) (offset = 238h)

The total number of good broadcast frames transmitted on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame destined for address FF-FF-FF-FF-FF-FFh only
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

32.5.50.16 Multicast Transmit Frames Register (TXMCASTFRAMES) (offset = 23Ch)

The total number of good multicast frames transmitted on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

32.5.50.17 Pause Transmit Frames Register (TXPAUSEFRAMES) (offset = 240h)

The total number of IEEE 802.3X pause frames transmitted by the EMAC. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect on this statistic. Pause frames sent by software are not included in this count. Since pause frames are only transmitted in full-duplex mode, carrier loss and collisions have no effect on this statistic.

Transmitted pause frames are always 64-byte multicast frames so appear in the multicast transmit frames register and 64 octect frames register statistics.

32.5.50.18 Deferred Transmit Frames Register (TXDEFERRED) (offset = 244h)

The total number of frames transmitted on the EMAC that first experienced deferment. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect on this statistic.

32.5.50.19 Transmit Collision Frames Register (TXCOLLISION) (offset = 248h)

The total number of times that the EMAC experienced a collision. Collisions occur under two circumstances:

- When a transmit data or MAC control frame has all of the following:
  - Was destined for any unicast, broadcast, or multicast address
  - Was any size
  - Had no carrier loss and no underrun
  - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic increments on each occasion if a frame experiences multiple collisions (and increments on late collisions).
- When the EMAC is in half-duplex mode, flow control is active, and a frame reception begins.

CRC errors have no effect on this statistic.

Copyright © 2018, Texas Instruments Incorporated

32.5.50.20 Transmit Single Collision Frames Register (TXSINGLECOLL) (offset = 24Ch)

The total number of frames transmitted on the EMAC that experienced exactly one collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect on this statistic.

32.5.50.21 Transmit Multiple Collision Frames Register (TXMULTICOLL) (offset = 250h)

The total number of frames transmitted on the EMAC that experienced multiple collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect on this statistic.

32.5.50.22 Transmit Excessive Collision Frames Register (TXEXCESSIVECOLL) (offset = 254h)

The total number of frames when transmission was abandoned due to excessive collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect on this statistic.

32.5.50.23 Transmit Late Collision Frames Register (TXLATECOLL) (offset = 258h)

The total number of frames when transmission was abandoned due to a late collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions that had previously required the transmission to be reattempted. The late collisions statistic dominates over the single, multiple, and excessive collisions statistics. If a late collision occurs, the frame is not counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect on this statistic.

32.5.50.24 Transmit Underrun Error Register (TXUNDERRUN) (offset = 25Ch)

The number of frames sent by the EMAC that experienced FIFO underrun. Late collisions, CRC errors, carrier loss, and underrun have no effect on this statistic.

Copyright © 2018, Texas Instruments Incorporated

32.5.50.25 Transmit Carrier Sense Errors Register (TXCARRIERSENSE) (offset = 260h)

The total number of frames on the EMAC that experienced carrier loss. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted)

CRC errors and underrun have no effect on this statistic.

32.5.50.26 Transmit Octet Frames Register (TXOCTETS) (offset = 264h)

The total number of bytes in all good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

32.5.50.27 Transmit and Receive 64 Octet Frames Register (FRAME64) (offset = 268h)

The total number of 64-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was exactly 64-bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame is recorded in this statistic).

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

32.5.50.28 Transmit and Receive 65 to 127 Octet Frames Register (FRAME65T127) (offset = 26Ch)

The total number of 65-byte to 127-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 65-bytes to 127-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

32.5.50.29 Transmit and Receive 128 to 255 Octet Frames Register (FRAME128T255) (offset = 270h)

The total number of 128-byte to 255-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 128-bytes to 255-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

Copyright © 2018, Texas Instruments Incorporated

32.5.50.30 Transmit and Receive 256 to 511 Octet Frames Register (FRAME256T511) (offset = 274h)

The total number of 256-byte to 511-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 256-bytes to 511-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

32.5.50.31 Transmit and Receive 512 to 1023 Octet Frames Register (FRAME512T1023) (offset = 278h)

The total number of 512-byte to 1023-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 512-bytes to 1023-bytes long

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

32.5.50.32 Transmit and Receive 1024 to RXMAXLEN Octet Frames Register (FRAME1024TUP) (offset = 27Ch)

The total number of 1024-byte to RXMAXLEN-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 1024-bytes to RXMAXLEN-bytes long

CRC/alignment/code errors, underruns, and overruns do not affect frame recording in this statistic.

32.5.50.33 Network Octet Frames Register (NETOCTETS) (offset = 280h)

The total number of bytes of frame data received and transmitted on the EMAC. Each frame counted has all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address (address match does not matter)
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced (multiple retries are counted each time)
- Every byte received if the EMAC is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence is not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns, and underruns do not affect the recording of bytes in this statistic. The objective of this statistic is to give a reasonable indication of Ethernet utilization.

Copyright © 2018, Texas Instruments Incorporated

32.5.50.34 Receive FIFO or DMA Start of Frame Overruns Register (RXSOFOVERRUNS) (offset = 284h)

The total number of frames received on the EMAC that had either a FIFO or DMA start of frame (SOF) overrun. An SOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available at the start of the frame).

CRC errors, alignment errors, and code errors have no effect on this statistic.

32.5.50.35 Receive FIFO or DMA Middle of Frame Overruns Register (RXMOFOVERRUNS) (offset = 288h)

The total number of frames received on the EMAC that had either a FIFO or DMA middle of frame (MOF) overrun. An MOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available after the frame was successfully started - no SOF overrun).

CRC errors, alignment errors, and code errors have no effect on this statistic.

32.5.50.36 Receive DMA Overruns Register (RXDMAOVERRUNS) (offset = 28Ch)

The total number of frames received on the EMAC that had either a DMA start of frame (SOF) overrun or a DMA middle of frame (MOF) overrun. A receive DMA overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception).

CRC errors, alignment errors, and code errors have no effect on this statistic.

Enhanced Capture (eCAP) Module

The enhanced Capture (eCAP) module is essential in systems where accurate timing of external events is important. This microcontroller implements 6 instances of the eCAP module.

Topic **Page**

33.1 Introduction **1928**
33.2 Basic Operation **1929**
33.3 Application of the ECAP Module **1936**
33.4 Application of the APWM Mode **1945**
33.5 eCAP Registers **1946**

Copyright © 2018, Texas Instruments Incorporated

33.1 Introduction

Uses for eCAP include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

33.1.1 Features

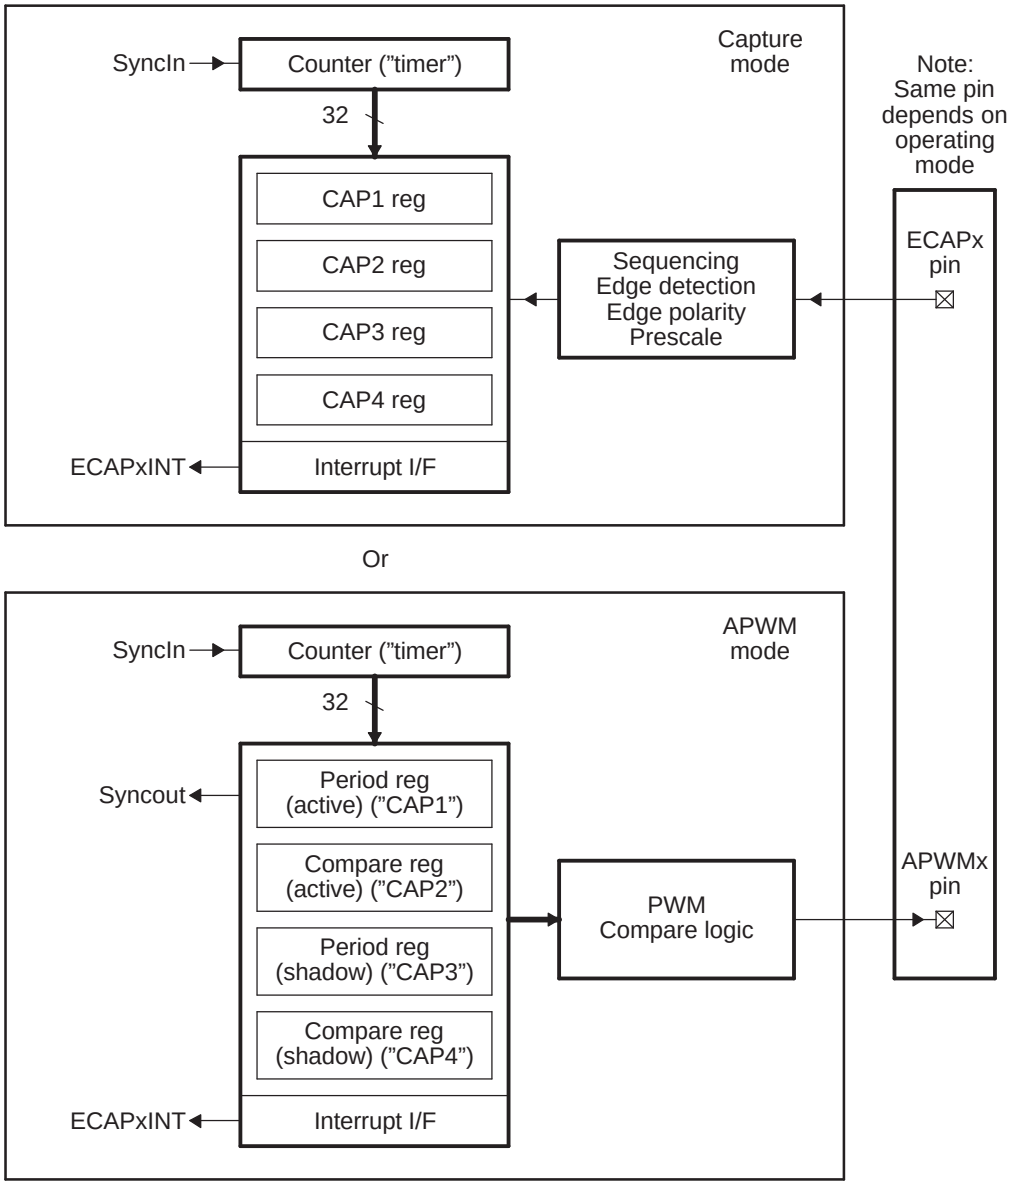
The eCAP module includes the following features:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

33.1.2 Description

One eCAP channel has the following independent key resources:

- Dedicated input capture pin
- 32-bit time base (counter)
- 4 x 32-bit time-stamp capture registers (CAP1-CAP4)
- 4-stage sequencer (Modulo4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2 to 62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the 4 capture events



Copyright © 2018, Texas Instruments Incorporated

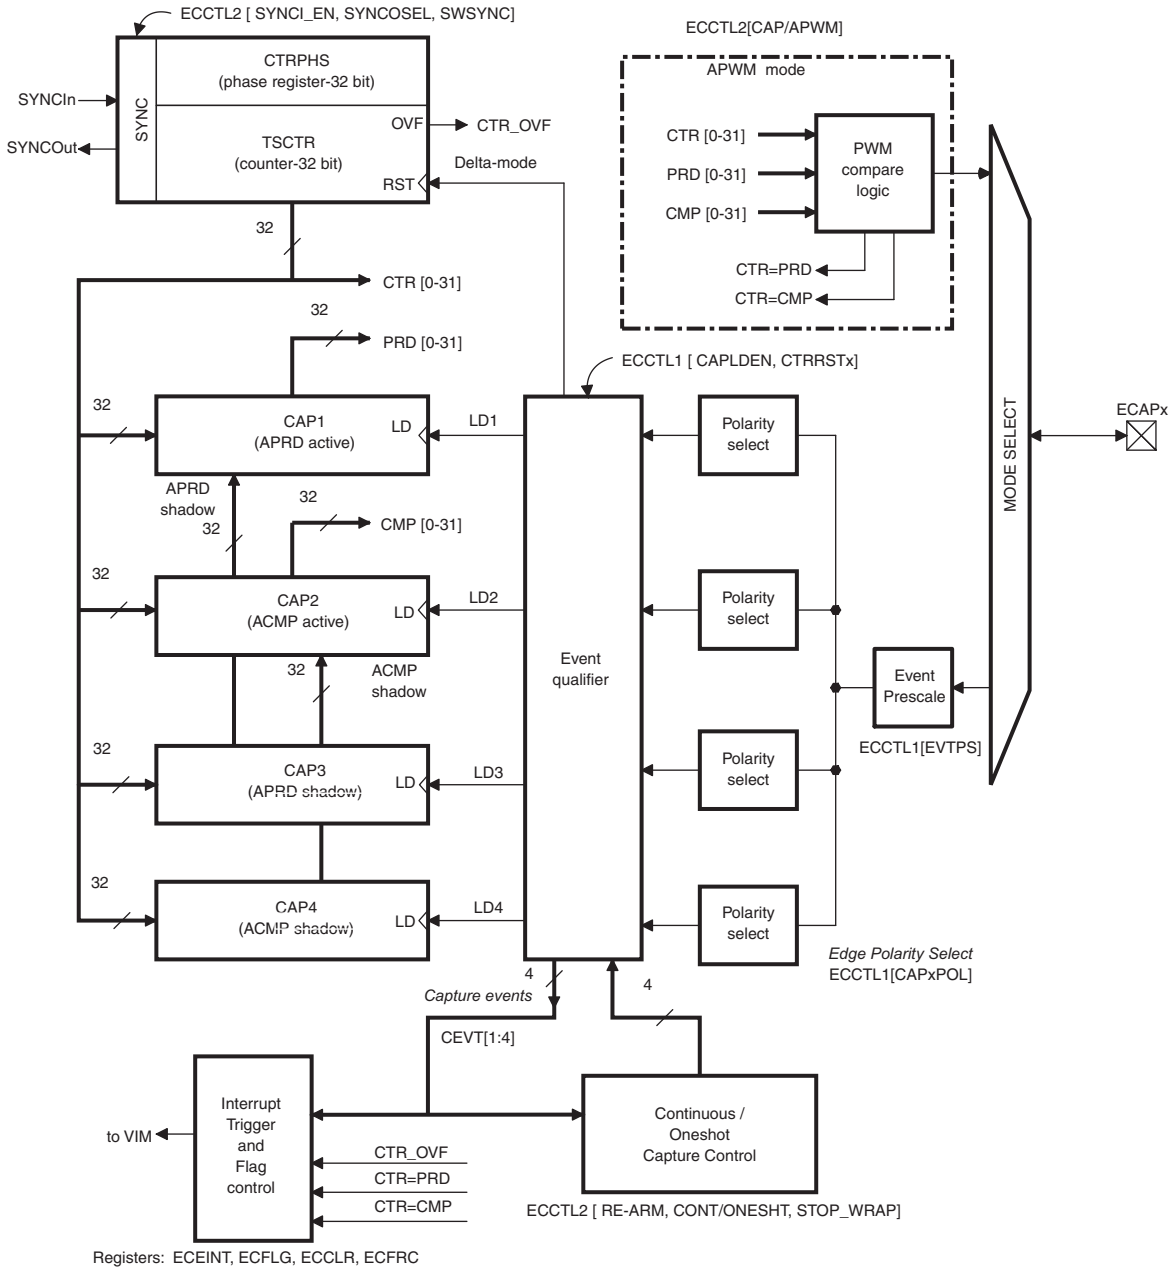
33.2 Basic Operation

33.2.1 Capture and APWM Operating Mode

You can use the eCAP module resources to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and capture shadow registers, respectively. Figure 33-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 33-1. Capture and APWM Modes of Operation

A A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.



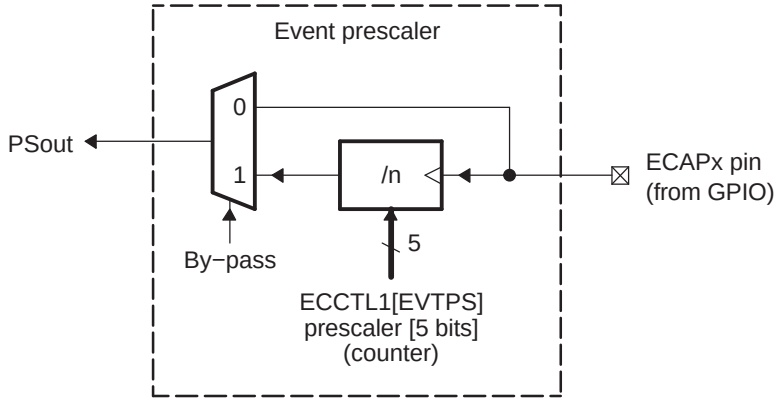
B In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

Copyright © 2018, Texas Instruments Incorporated

33.2.2 Capture Mode Description

Figure 33-2 shows the various components that implement the capture function.

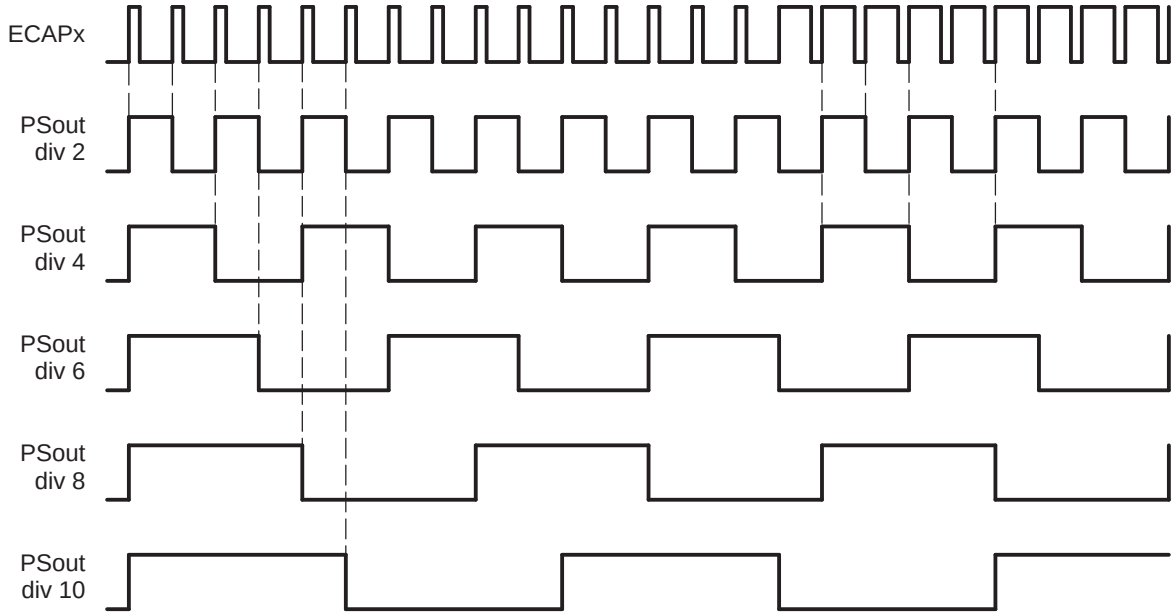
Figure 33-2. Capture Function Diagram



33.2.2.1 Event Prescaler

- An input capture signal (pulse train) can be prescaled by N = 2-62 (in multiples of 2) or can bypass the prescaler.

  This is useful when very high frequency signals are used as inputs. Figure 33-3 shows a functional diagram and Figure 33-4 shows the operation of the prescale function.



Copyright © 2018, Texas Instruments Incorporated

Figure 33-3. Event Prescale Control

A When a prescale value of 1 is chosen (ECCTL1[13:9] = 0,0,0,0,0), the input capture signal by-passes the prescale logic completely.

Figure 33-4. Prescale Function Waveforms

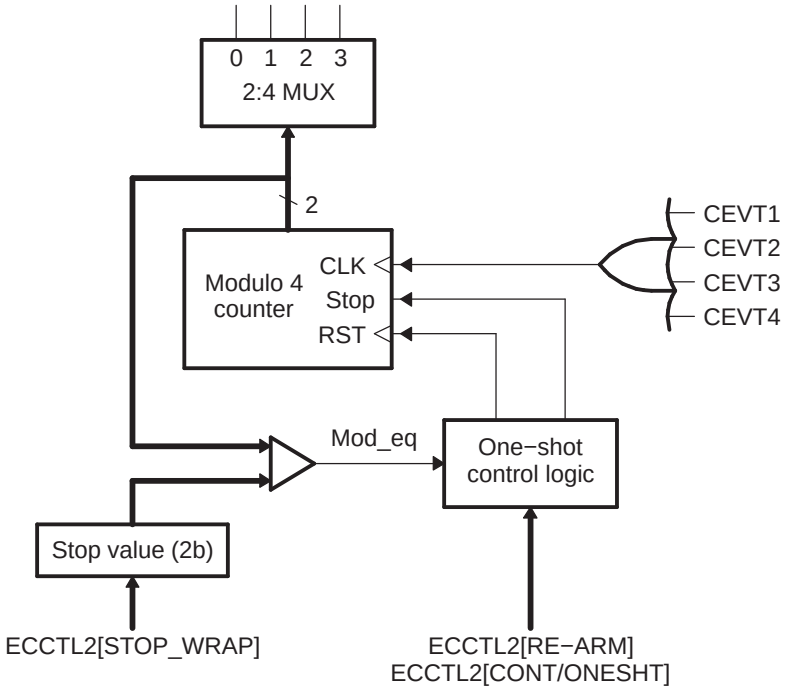
33.2.2.2 Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection MUXes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

Copyright © 2018, Texas Instruments Incorporated

33.2.2.3 Continuous/One-Shot Control

- The Mod4 (2 bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output, and when equal stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. This occurs during one-shot operation.



The continuous/one-shot block controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

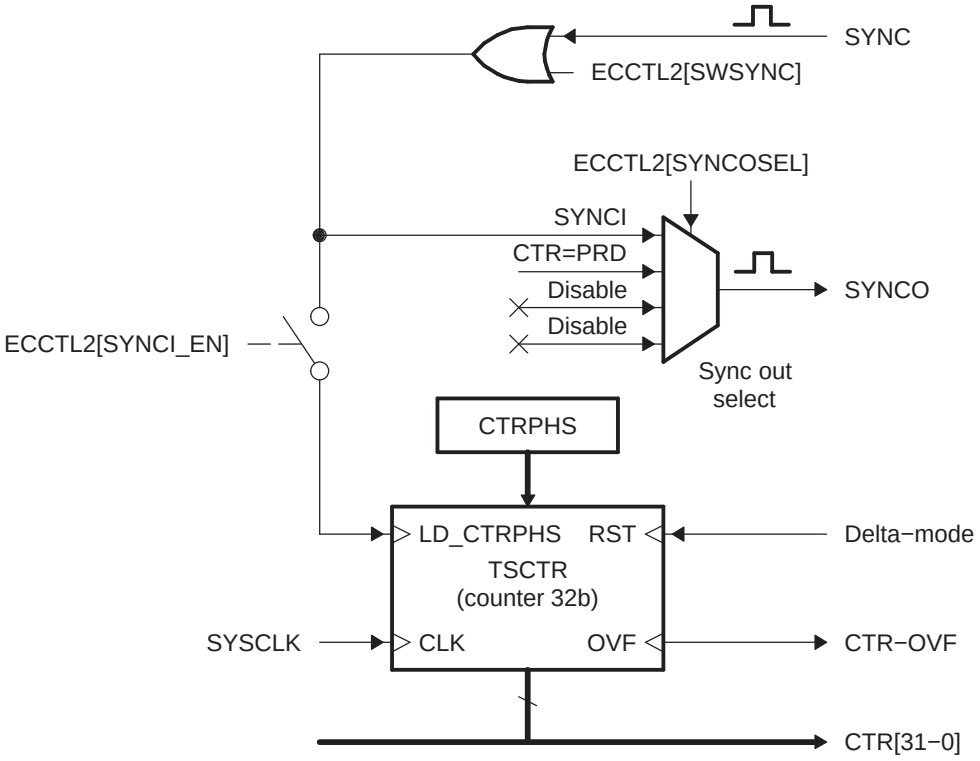
Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time-stamps).

Re-arming prepares the eCAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

Figure 33-5. Continuous/One-shot Block

33.2.2.4 32-Bit Counter and Phase Control



This counter provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

Copyright © 2018, Texas Instruments Incorporated

Figure 33-6. Counter and Synchronization Block

33.2.2.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (that is, capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via control bit CAPLDEN. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

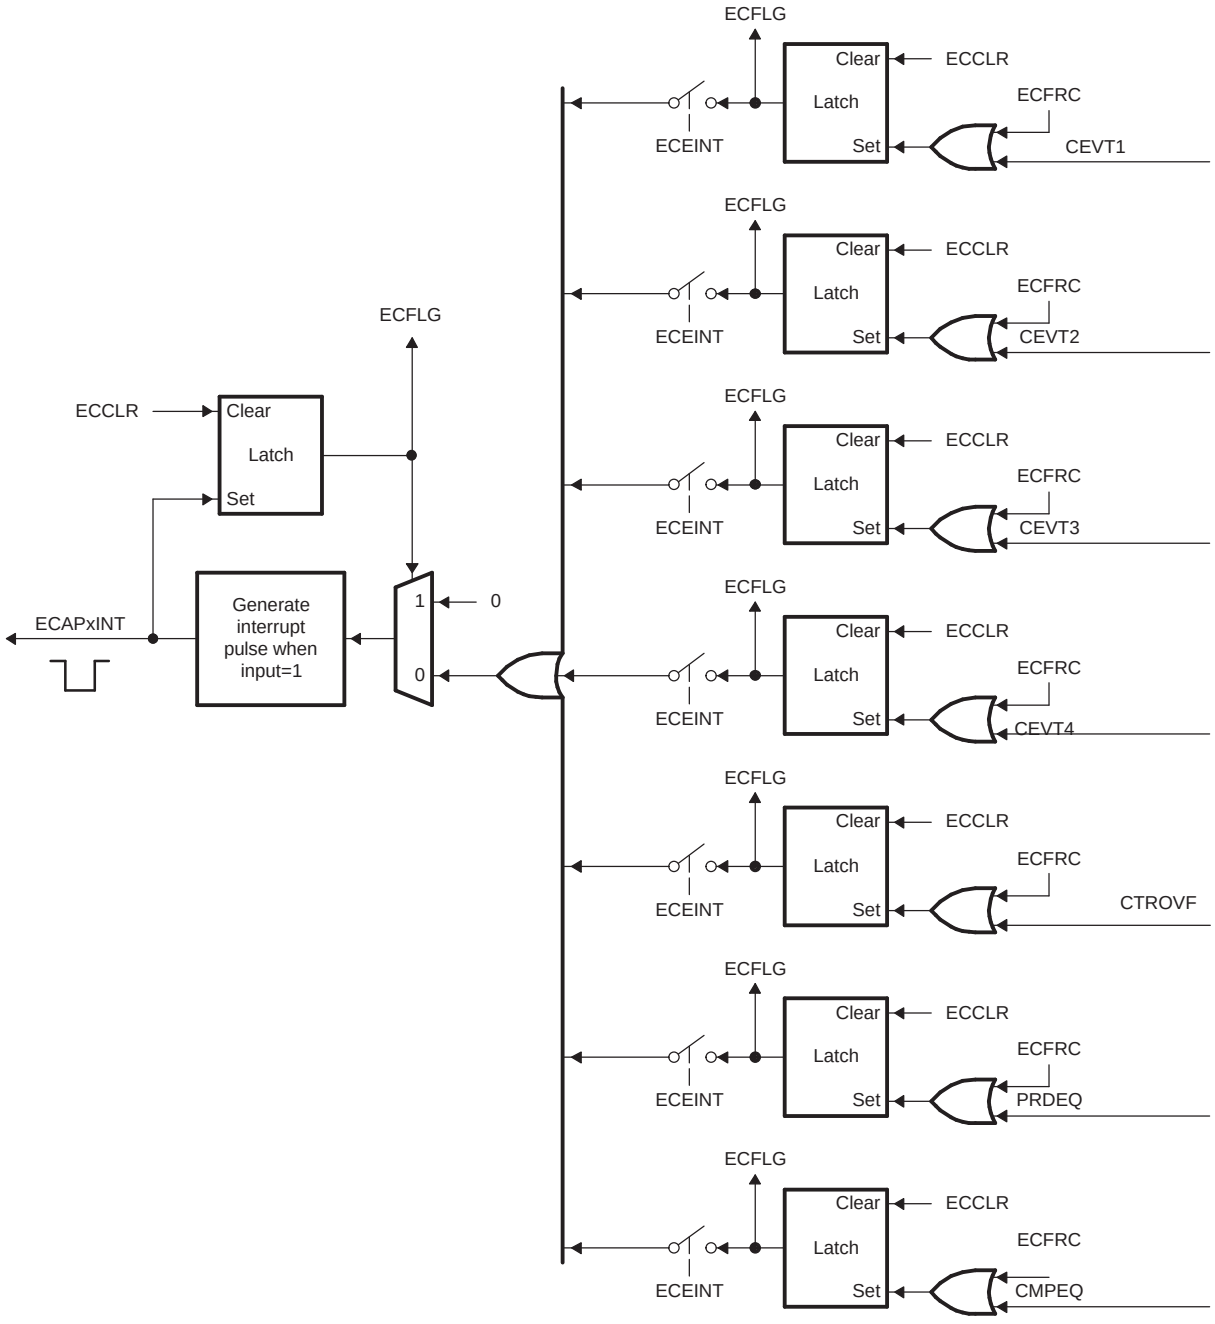
CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

33.2.2.6 Interrupt Control

An Interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).

A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).

The capture events are edge and sequencer qualified (ordered in time) by the polarity select and Mod4 gating, respectively.



One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR = PRD, CTR = CMP) can be generated. The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECCLR) before any other interrupt pulses are generated. You can force an interrupt event via the interrupt force register (ECFRC). This is useful for test purposes.

Copyright © 2018, Texas Instruments Incorporated

Note: The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP_APWM == 0]). The CTR_PRD and CTR_CMP flags are only valid in APWM mode (ECCTL2[CAP_APWM == 1]). CNTOVF flag is valid in both modes.

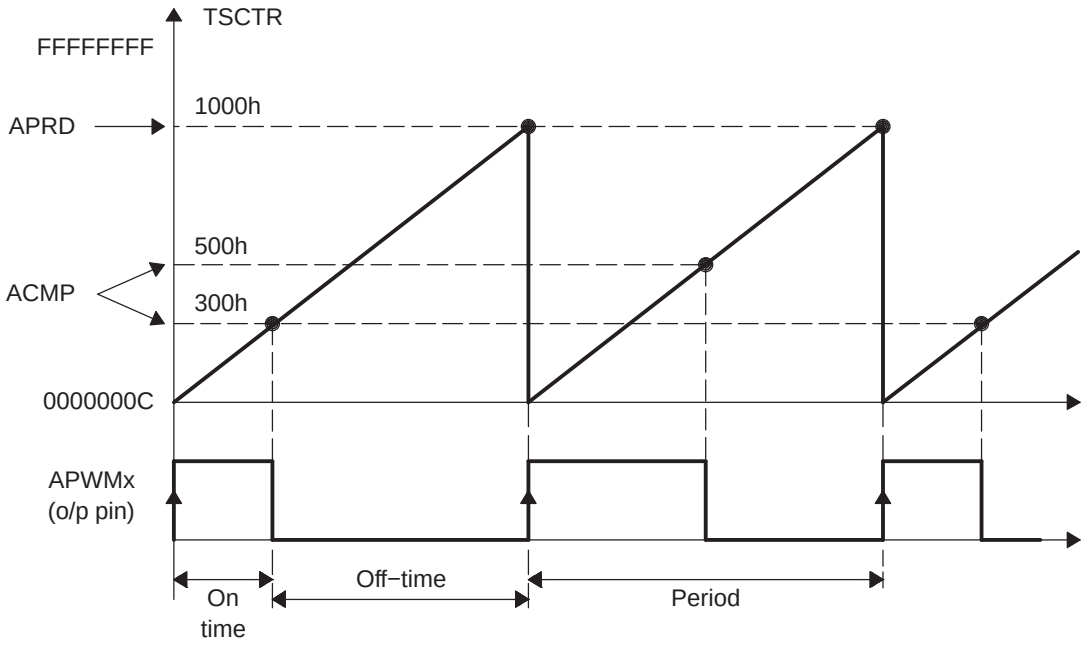
Figure 33-7. Interrupts in eCAP Module

33.2.2.7 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0]



Copyright © 2018, Texas Instruments Incorporated

33.2.2.8 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers either immediately upon a write, or on a CTR = PRD trigger.
- In APWM mode, writing to CAP1/CAP2 active registers will also write the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, you only need to use the shadow registers.

Figure 33-8. PWM Waveform Details of APWM Mode Operation

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

```
CMP = 0x00000000, output low for duration of period (0% duty)
CMP = 0x00000001, output high 1 cycle
CMP = 0x00000002, output high 2 cycles
CMP = PERIOD, output high except for 1 cycle (<100% duty)
CMP = PERIOD+1, output high for complete period (100% duty)
CMP > PERIOD+1, output high for complete period
```

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

```
CMP = 0x00000000, output high for duration of period (0% duty)
CMP = 0x00000001, output low 1 cycle
CMP = 0x00000002, output low 2 cycles
CMP = PERIOD, output low except for 1 cycle (<100% duty)
CMP = PERIOD+1, output low for complete period (100% duty)
CMP > PERIOD+1, output low for complete period
```

33.3.1 Example 1 - Absolute Time-Stamp Operation Rising Edge Trigger

Figure 33-9 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFFFFFF (maximum value), it wraps around to 00000000 (not shown in Figure 33-9), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs, CTROVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram, after the 4th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

33.3.2 Example 2 - Absolute Time-Stamp Operation Rising and Falling Edge Trigger

In Figure 33-10, the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information: Period1 = $t_3 - t_1$, Period2 = $t_5 - t_3$, …etc. Duty Cycle1 (on-time %) = $(t_2 - t_1)$ / Period1 x 100%, etc. Duty Cycle1 (off-time %) = $(t_3 - t_2)$ / Period1 x 100%, etc.

33.3.3 Example 3 - Time Difference (Delta) Operation Rising Edge Trigger

Figure 33-11 shows an example of how the eCAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (Time-Stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFFFFFF (maximum value), before the next event, it wraps around to 00000000 and continues, a CNTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAPx contents directly give timing data without the need for CPU calculations: Period1 = T_1, Period2 = T_2,…etc. As shown in the diagram, the CEVT1 event is a good trigger point to read the timing data, T_1, T_2, T_3, T_4 are all valid here.

Figure 33-11. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect

33.3.4 Example 4 - Time Difference (Delta) Operation Rising and Falling Edge Trigger

In Figure 33-12, the eCAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information: Period1 = T_1+T_2, Period2 = T_3+T_4, …etc Duty Cycle1 (on-time %) = T_1 / Period1 x 100%, etc Duty Cycle1 (off-time %) = T_2 / Period1 x 100%, etc

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, during run-time, only the shadow registers must be used.

33.4 Application of the APWM Mode

In this section, the eCAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWMx. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time. Note here values are in hexadecimal (“h”) notation.

33.4.1 Simple PWM Generation (Independent Channel/s)

Figure 33-13. PWM Waveform Details of APWM Mode Operation

33.4.1.1 Code Snippet for APWM Mode

```
// Code snippet for APWM mode Example 1
 // Initialization Time
 //======================
 // ECAP module 1 config
 ECap1Regs.CAP1 = 0x1000; // Set period value
 ECap1Regs.CTRPHS = 0x0; // make phase zero
 ECap1Regs.ECCTL2.bit.CAP_APWM = EC_APWM_MODE;
 ECap1Regs.ECCTL2.bit.APWMPOL = EC_ACTV_HI; // Active high
 ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE; // Synch not used
 ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS; // Synch not used
 ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
 // Run Time (Instant 1, e.g. ISR call)
 //======================
 ECap1Regs.CAP2 = 0x300; // Set Duty cycle i.e. compare value
 // Run Time (Instant 2, e.g. another ISR call)
 //======================
 ECap1Regs.CAP2 = 0x500; // Set Duty cycle i.e. compare value
```

33.5.7 ECAP Control Register 2 (ECCTL2)

Figure 33-20. ECAP Control Register 2 (ECCTL2) [offset = 28h]

15	11	10	9	8
Reserved		APWMPOL	CAP_APWM	SWSYNC
R-0		R/W-0	R/W-0	R/W-0

7	6	5	4	3	2	1	0
SYNCO_SEL		SYNCI_EN	TSCTRSTOP	REARM	STOP_WRAP		CONT_ONESHT
R/W-0		R/W-0	R/W-0	R/W-0	R/W-3h		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 33-8. ECAP Control Register 2 (ECCTL2) Field Descriptions

Bits	Field	Value	Description
15-11	Reserved	0	Reserved
10	APWMPOL		APWM output polarity select. This is applicable only in APWM operating mode.
		0	Output is active-high (Compare value defines high time).
		1	Output is active-low (Compare value defines low time).
9	CAP_APWM		CAP/APWM operating mode select.
		0	ECAP module operates in capture mode. This mode forces the following configuration: • Inhibits TSCTR resets via CTR = PRD event • Inhibits shadow loads on CAP1 and 2 registers • Permits user to enable CAP1-4 register load • CAPx/APWMx pin operates as a capture input
		1	ECAP module operates in APWM mode. This mode forces the following configuration: • Resets TSCTR on CTR = PRD event (period boundary • Permits shadow loading on CAP1 and 2 registers • Disables loading of time-stamps into CAP1-4 registers • CAPx/APWMx pin operates as a APWM output
8	SWSYNC		Software-forced Counter (TSCTR) Synchronizing. This provides a convenient software method to synchronize some or all ECAP time bases. In APWM mode, the synchronizing can also be done via the CTR = PRD event.
		0	Writing a 0 has no effect. Reading always returns a 0.
		1	Writing a 1 forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to a 0. Note: Selection CTR = PRD is meaningful only in APWM mode; however, you can choose it in CAP mode if you find doing so useful.
7-6	SYNCO_SEL		Sync-Out select.
		0	Select sync-in event to be the sync-out signal (pass through).
		1h	Select CTR = PRD event to be the sync-out signal.
		2h	Disable sync out signal.
		3h	Disable sync out signal.
5	SYNCI_EN		Counter (TSCTR) Sync-In select mode.
		0	Disable sync-in option.
		1	Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCI signal or a S/W force event.
4	TSCTRSTOP		Time Stamp (TSCTR) Counter Stop (freeze) Control.
		0	TSCTR is stopped.
		1	TSCTR is free-running.

Table 33-8. ECAP Control Register 2 (ECCTL2) Field Descriptions (continued)

Bits	Field	Value	Description
3	REARM		One-Shot Re-Arming Control, wait for stop trigger. Note: The re-arm function is valid in one shot or continuous mode.
		0	Has no effect (reading always returns a 0).
		1	Arms the one-shot sequence as follows: 1) Resets the Mod4 counter to 0 2) Unfreezes the Mod4 counter 3) Enables capture register loads
2-1	STOP_WRAP		Stop value for one-shot mode. This is the number (between 1-4) of captures allowed to occur before the CAP(1-4) registers are frozen, capture sequence is stopped. Wrap value for continuous mode. This is the number (between 1-4) of the capture register in which the circular buffer wraps around and starts again.
		0	Stop after Capture Event 1 in one-shot mode. Wrap after Capture Event 1 in continuous mode.
		1h	Stop after Capture Event 2 in one-shot mode. Wrap after Capture Event 2 in continuous mode.
		2h	Stop after Capture Event 3 in one-shot mode. Wrap after Capture Event 3 in continuous mode.
		3h	Stop after Capture Event 4 in one-shot mode. Wrap after Capture Event 4 in continuous mode.
			Notes: STOP_WRAP is compared to Mod4 counter and, when equal, 2 actions occur: • Mod4 counter is stopped (frozen) • Capture register loads are inhibited In one-shot mode, further interrupt events are blocked until re-armed.
0	CONT_ONESHT		Continuous or one-shot mode control (applicable only in capture mode).
		0	Operate in continuous mode.
		1	Operate in one-shot mode.

33.5.10 ECAP Interrupt Enable Register (ECEINT)

The interrupt enable bits block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers.

The proper procedure for configuring peripheral modes and interrupts is as follows:

- Disable global interrupts
- Stop eCAP counter
- Disable eCAP interrupts
- Configure peripheral registers
- Clear spurious eCAP interrupt flags
- Enable eCAP interrupts
- Start eCAP counter
- Enable global interrupts

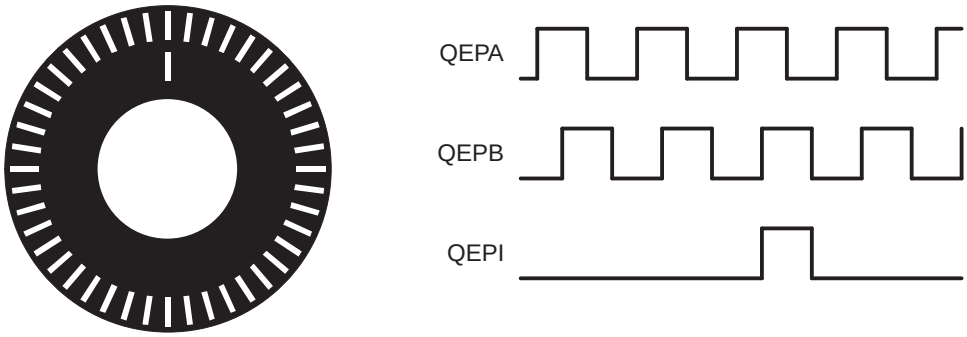
Enhanced Quadrature Encoder Pulse (eQEP) Module

The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system. This microcontroller implements 2 instances of the eQEP module.

Topic **Page**



34.1 Introduction **1958**
34.2 Basic Operation **1960**
34.3 eQEP Registers **1978**

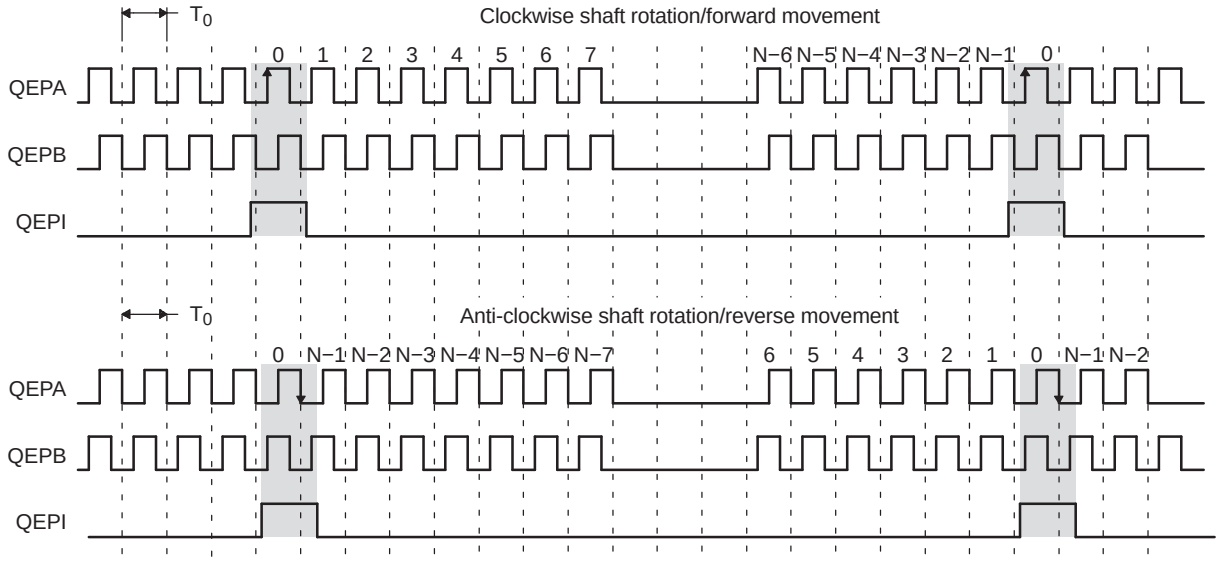
34.1 Introduction

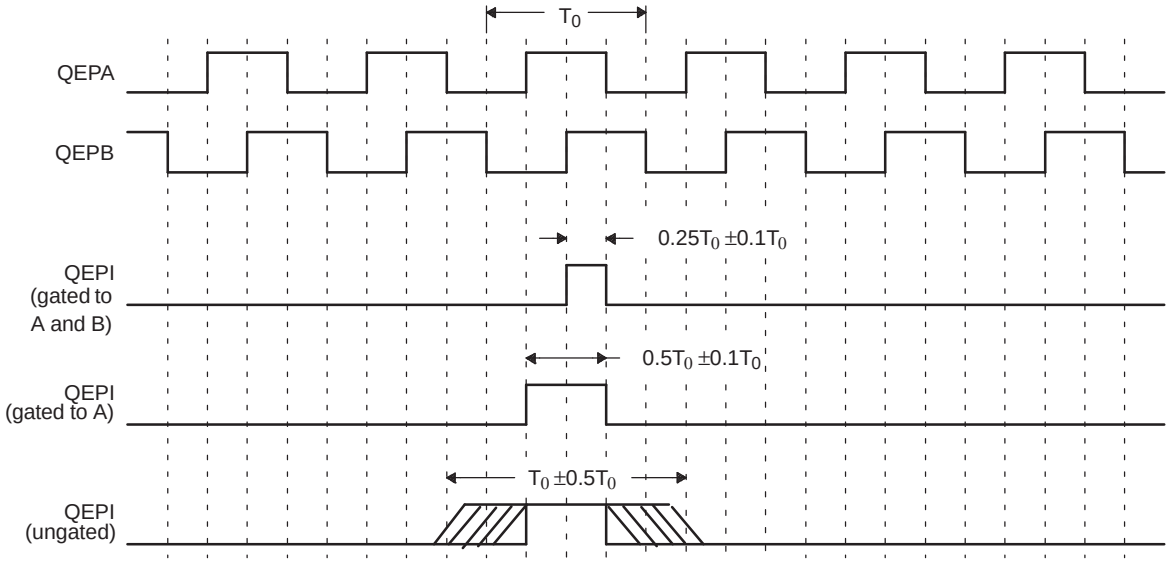


A single track of slots patterns the periphery of an incremental encoder disk, as shown in Figure 34-1. These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference.

Figure 34-1. Optical Encoder Disk

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90° out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vise versa as shown in Figure 34-2.

Figure 34-2. QEP Encoder Output Signal for Forward/Reverse Movement



Legend: N = lines per revolution

The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 KHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Copyright © 2018, Texas Instruments Incorporated

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 34-3. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

Figure 34-3. Index Pulse Example

Some typical applications of shaft encoders include robotics and even computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

General Issues: Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$v(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (68)$$

$$v(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (69)$$

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k-1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

t(k): Time instant "k"

t(k-1): Time instant "k-1"

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement.

Equation 68 is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

Copyright © 2018, Texas Instruments Incorporated

The encoder count (position) is read once during each unit time event. The quantity [x(k) - x(k-1)] is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant 1/T (where T is the constant time between unit time events and is known in advance).

Estimation based on Equation 68 has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T. For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, e.g. 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, Equation 69 provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. Equation 69 can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does Equation 68. A combination of relatively large motor speeds and high sensor resolution makes the time interval ΔT small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use Equation 69 at low speed and have the DSP software switch over to Equation 68 when the motor speed rises above some specified threshold.

34.2 Basic Operation

34.2.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

- *QEPA/XCLK and QEPB/XDIR*

  These two pins can be used in quadrature-clock mode or direction-count mode.

  – *Quadrature-clock Mode*

    The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.

  – *Direction-count Mode*

    In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.

- *eQEPI: Index or Zero Marker*

  The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.

- QEPS: *Strobe Input*

  This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

34.2.2 Functional Description

The eQEP peripheral contains the following major functional units (as shown in Figure 34-4):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)

34.2.2.2 Quadrature Decoder Unit (QDU)

Figure 34-5 shows a functional block diagram of the QDU.

Figure 34-5. Functional Block Diagram of Decoder Unit

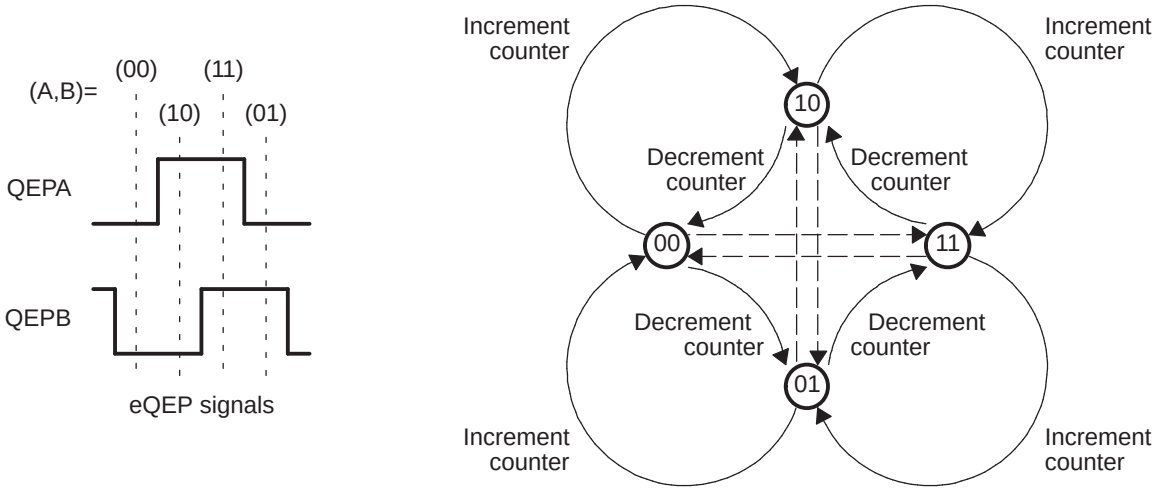
34.2.2.2.1 Position Counter Input Modes

Clock and direction input to position counter is selected using QDECCTL[QSRC] bits, based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

Copyright © 2018, Texas Instruments Incorporated

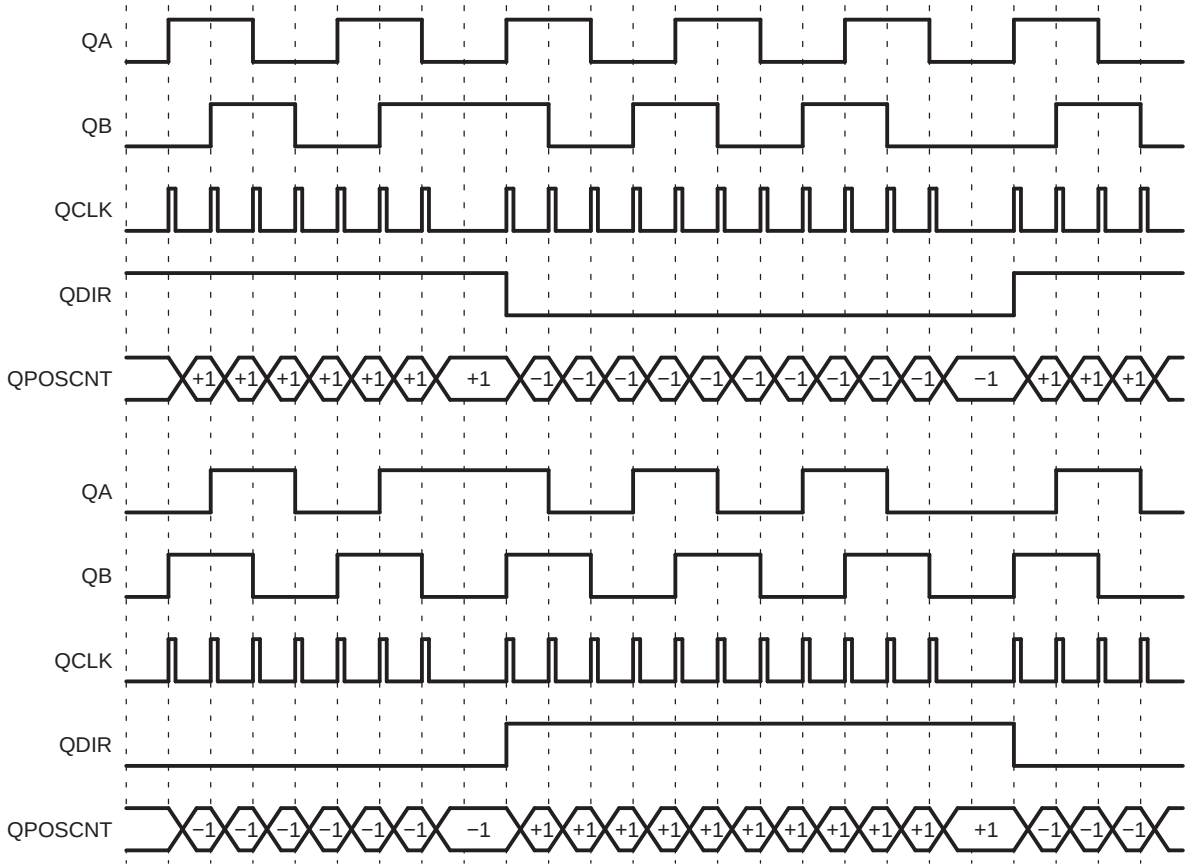
34.2.2.2.1.1 Quadrature Count Mode



The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

Direction Decoding— The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in QEPSTS[QDF] bit. Table 34-2 and Figure 34-6 show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. Figure 34-7 shows the direction decoding and clock generation from the eQEP input signals.

Table 34-2. Quadrature Decoder Truth Table



Previous Edge	Present Edge	QDIR	QPOSCNT
QA↑	QB↑	UP	Increment

	QA↑	UP	Decrement
	QB↑	TOGGLE	Increment or Decrement

Figure 34-6. Quadrature Decoder State Machine

Copyright © 2018, Texas Instruments Incorporated

Figure 34-7. Quadrature-clock and Direction Decoding

Phase Error Flag— In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in Figure 34-6 are invalid transitions that generate a phase error.

Count Multiplication— The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in Figure 34-7.

Reverse Count— In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the QDECCTL register. This will swap the input to the quadrature decoder thereby reversing the counting direction.

34.2.2.2.1.2 Direction-count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high and decremented when the direction input is low.

34.2.2.2.1.3 Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the QEPA input. Setting of the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2x factor.

Copyright © 2018, Texas Instruments Incorporated

34.2.2.2.1.4 Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the QEPA input. Setting of the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by 2x factor.

34.2.2.2.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using QDECCTL[8:5] control bits. As an example, setting of QDECCTL[QIP] bit will invert the index input.

34.2.2.2.3 Position-Compare Sync Output

The enhanced eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (QPOSCNT) and the position-compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the QDECCTL[SOEN] bit enables the position-compare sync output and the QDECCTL[SPSEL] bit selects either an eQEP index pin or an eQEP strobe pin.

34.2.2.3 Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

34.2.2.3.1 Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

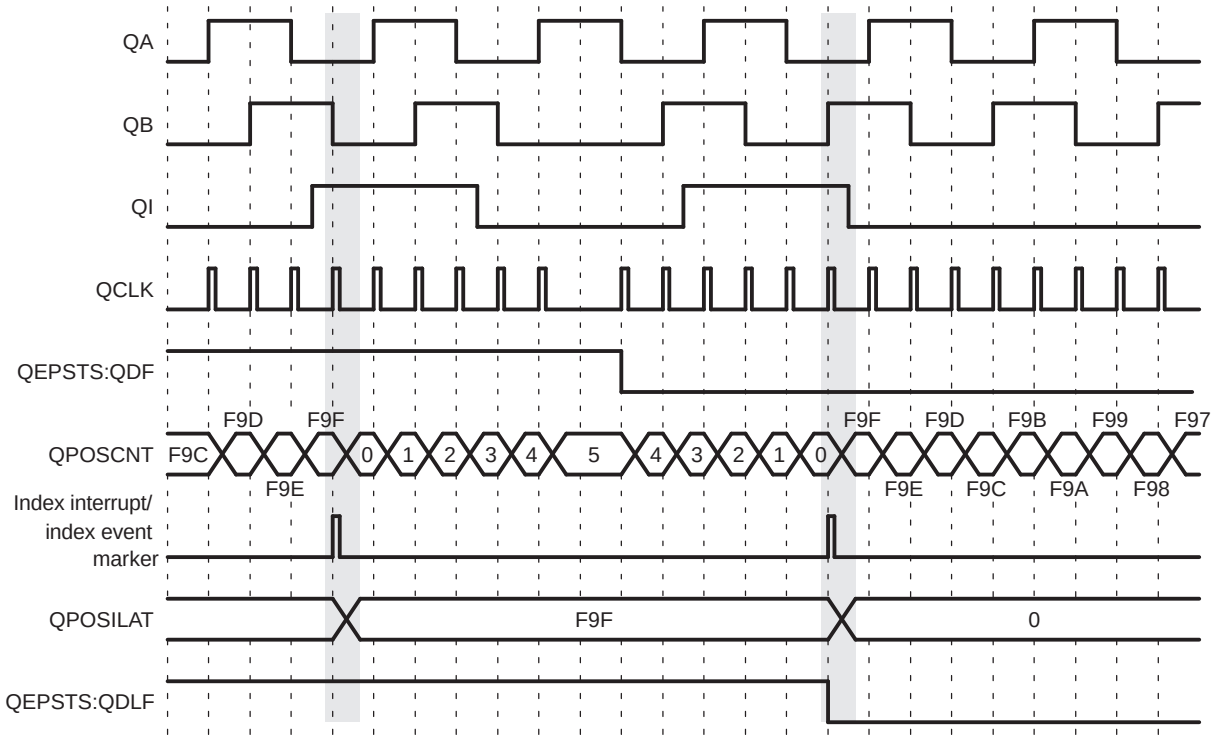
- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, position counter is reset to 0 on overflow and to QPOSMAX register value on underflow. Overflow occurs when the position counter counts up after QPOSMAX value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in QFLG register.

Copyright © 2018, Texas Instruments Incorporated

34.2.2.3.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM] = 00)

If the index event occurs during the forward movement, then position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock.



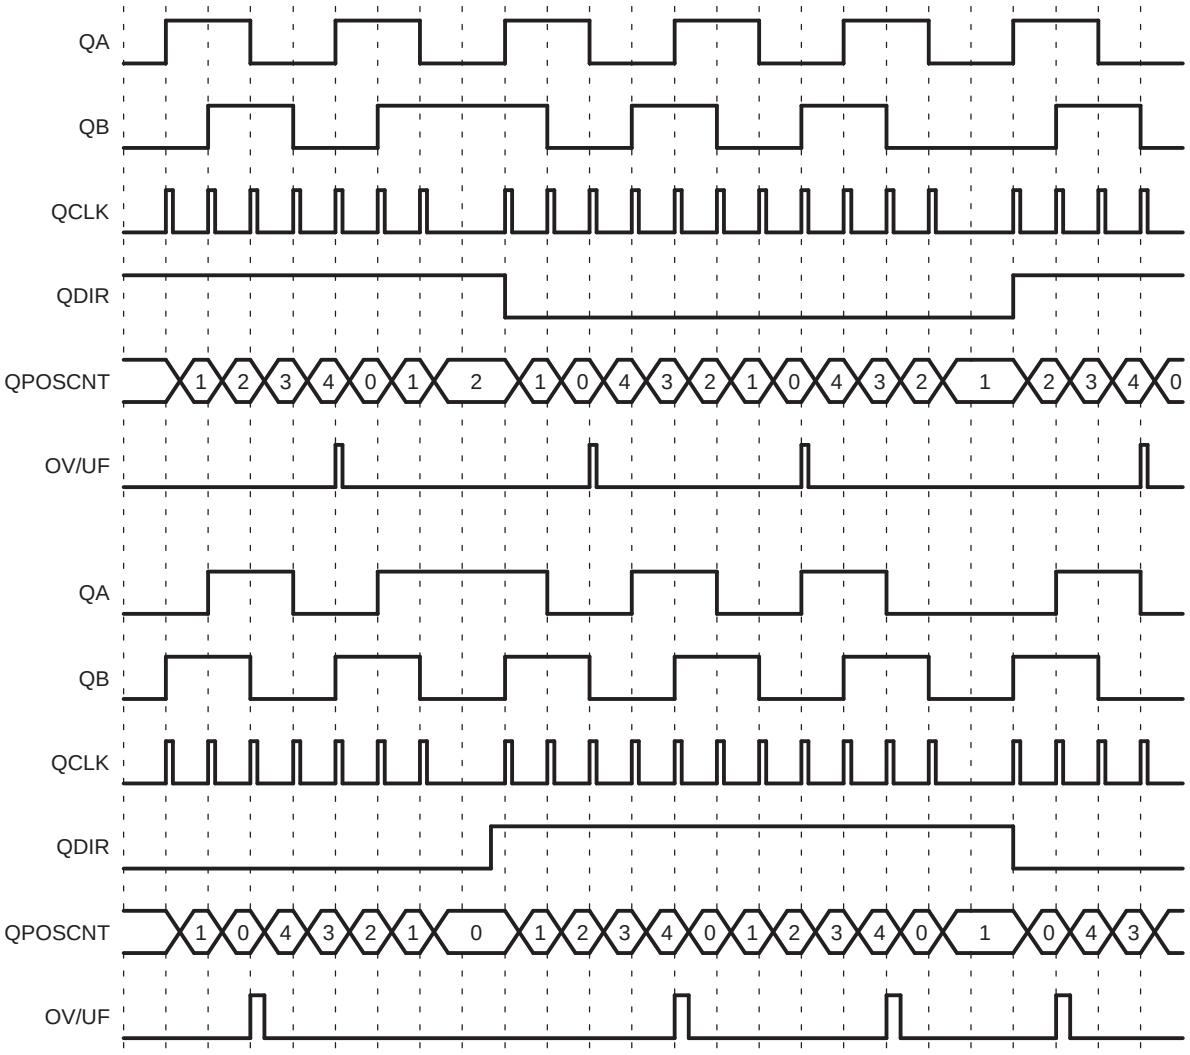
First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 34-8.

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

Figure 34-8. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOSMAX = 3999 or F9Fh)



Copyright © 2018, Texas Instruments Incorporated

34.2.2.3.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM] = 01)

If the position counter is equal to QPOSMAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 34-9 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers; it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (QEPCTL[IEL]=11).

Figure 34-9. Position Counter Underflow/Overflow (QPOSMAX = 4)

Copyright © 2018, Texas Instruments Incorporated

34.2.2.3.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in Section 34.2.2.3.1.2.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (QEPCTL[IEL]=11).

34.2.2.3.1.4 Position Counter Reset on Unit Time out Event (QEPCTL[PCRM] = 11)

In this mode, the QPOSCNT value is latched to the QPOSLAT register and then the QPOSCNT is reset (to 0 or QPOSMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event). This is useful for frequency measurement.

34.2.2.3.2 Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

34.2.2.3.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

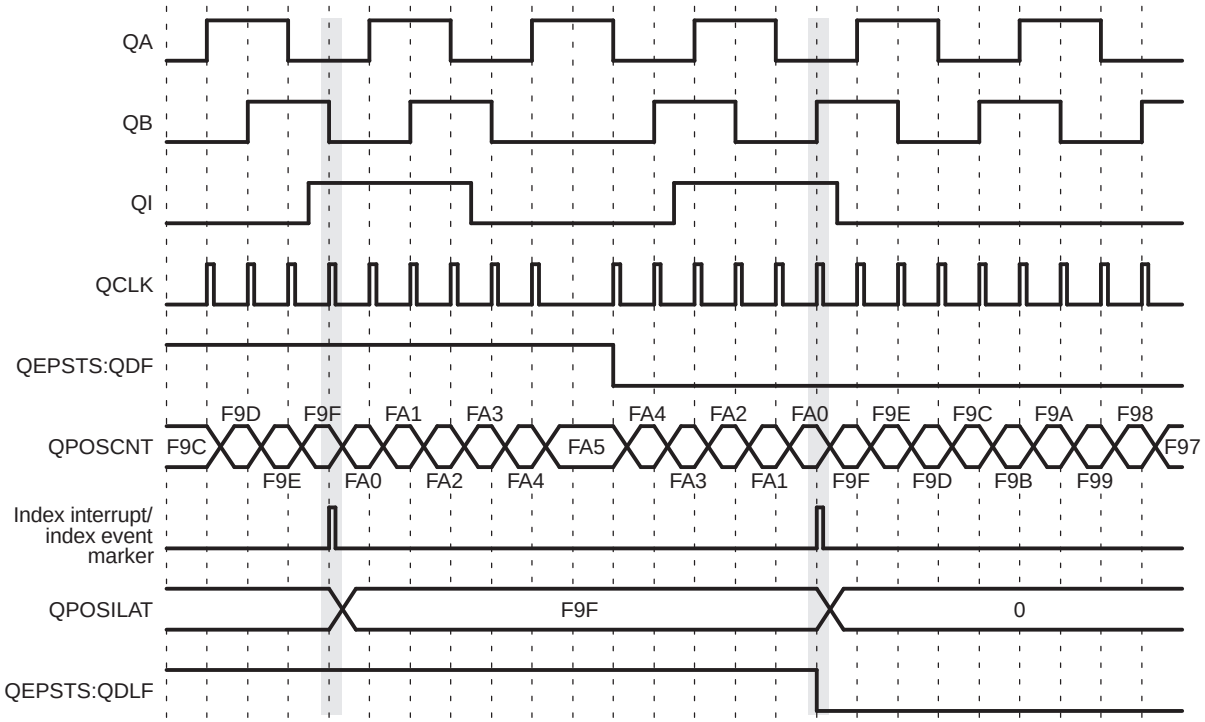
In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL]=01)
- Latch on Falling edge (QEPCTL[IEL]=10)
- Latch on Index Event Marker (QEPCTL[IEL]=11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when QEPCTL[PCRM] = 00.

Latch on Rising Edge (QEPCTL[IEL]=01)— The position counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.



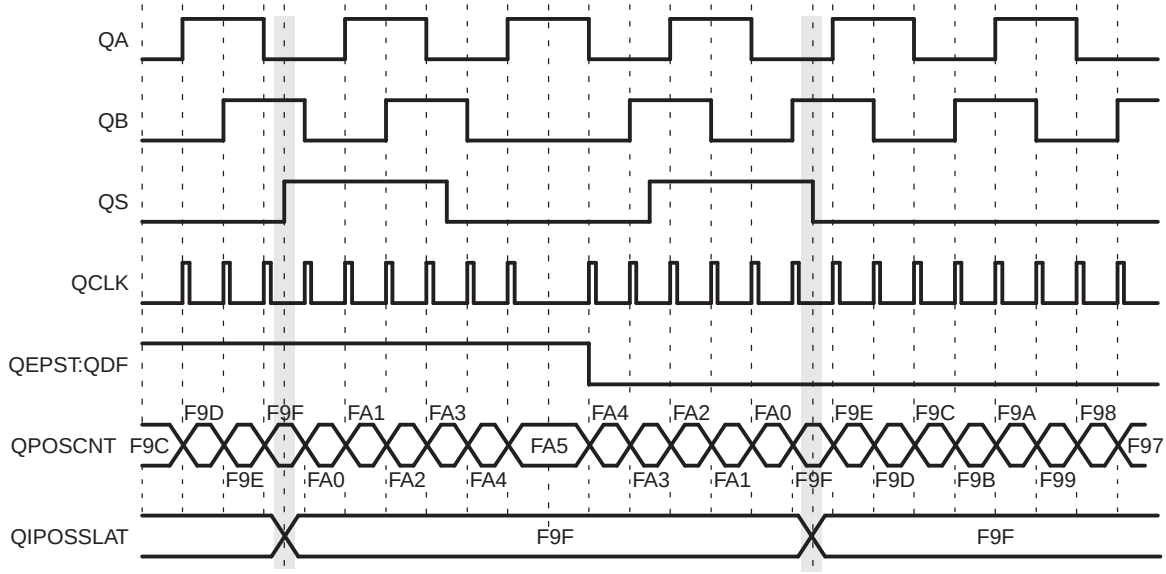
Latch on Falling Edge (QEPCTL[IEL] = 10)— The position counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.

Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11— The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (QEPCTL[IEL]=11).

Figure 34-10 shows the position counter latch using an index event marker.

Copyright © 2018, Texas Instruments Incorporated

Figure 34-10. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)



34.2.2.3.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in Figure 34-11.

The strobe event latch interrupt flag (QFLG[SEL) is set when the position counter is latched to the QPOSSLAT register.

Figure 34-11. Strobe Event Latch (QEPCTL[SEL] = 1)

Copyright © 2018, Texas Instruments Incorporated

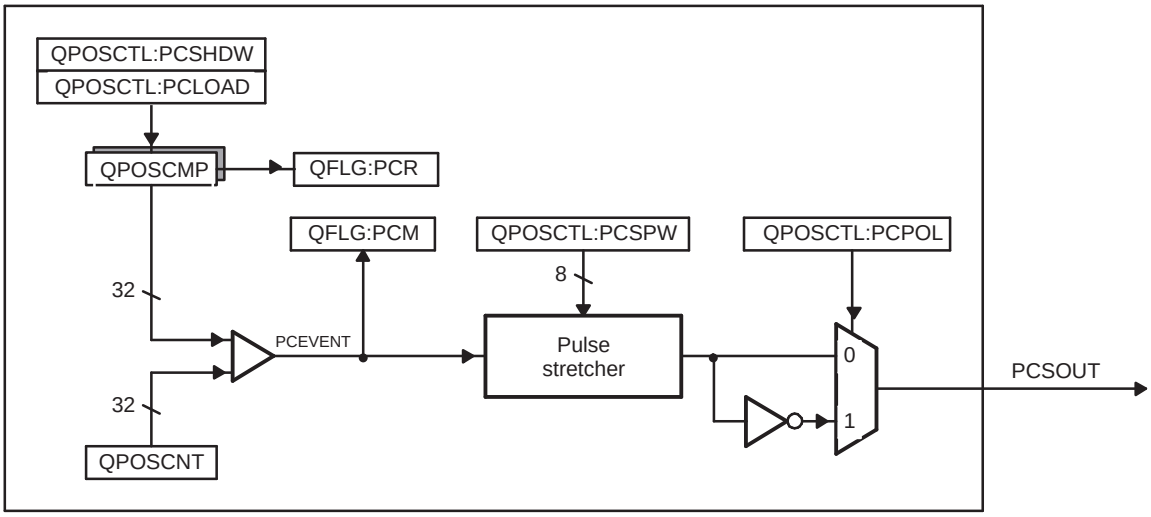
34.2.2.3.3 Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

Index Event Initialization (IEI)— The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input. If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of index input. Conversely, if the QEPCTL[IEI] bits are 11, initialization will be on the falling edge of the index input.

Strobe Event Initialization (SEI)— If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input.



If QEPCTL[SEL] bits are 11, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

Software Initialization (SWI)— The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit. This bit is not automatically cleared. While the bit is still set, if a 1 is written to it again, the position counter will be re-initialized.

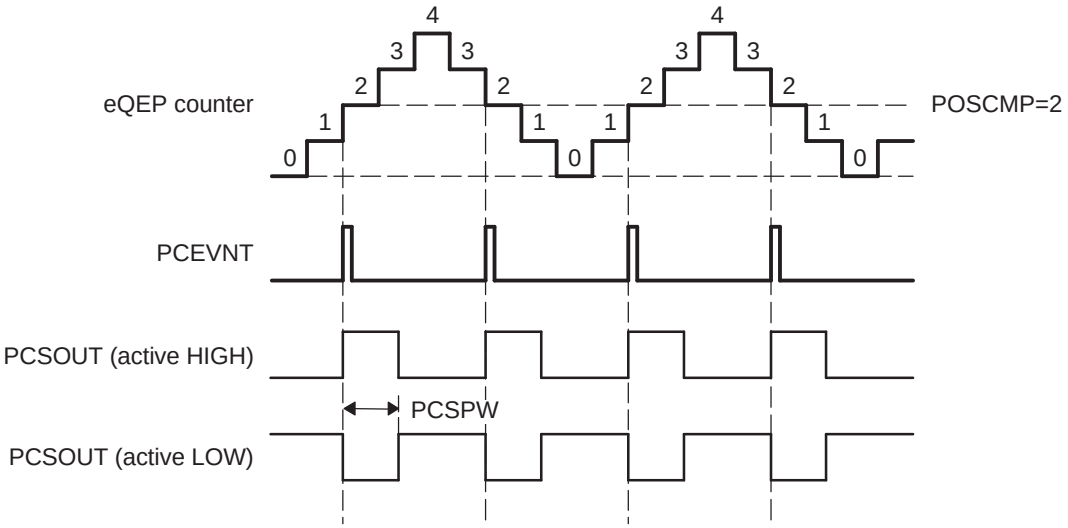
34.2.2.3.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 34-12 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

Figure 34-12. eQEP Position-compare Unit

In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

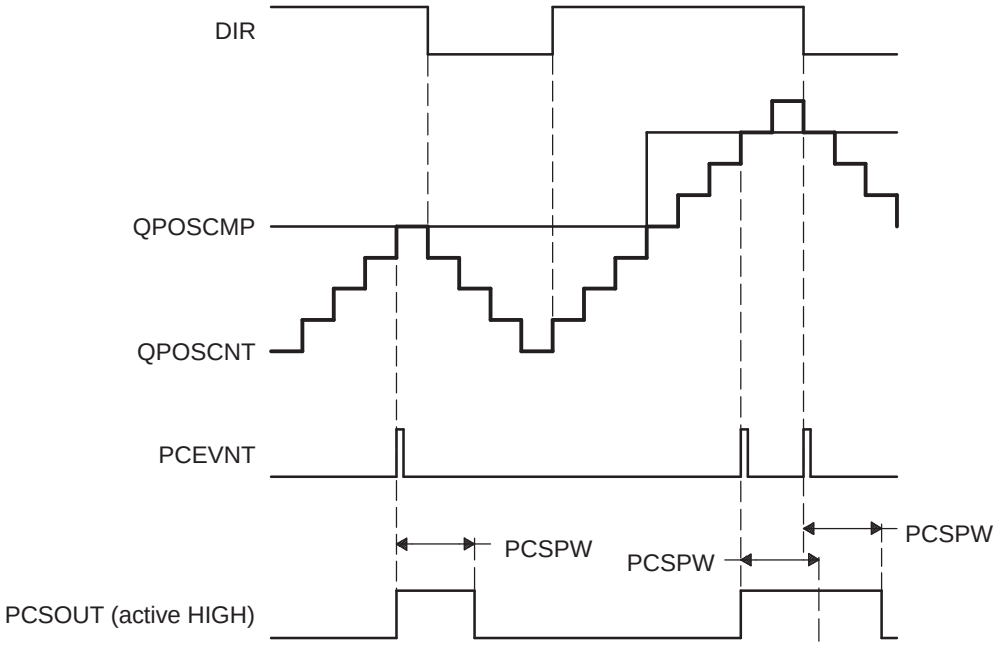
- Load on compare match
- Load on position-counter zero event



The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

Copyright © 2018, Texas Instruments Incorporated

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 34-13).



Section 34.3.14 shows the layout of the eQEP Position-Compare Control Register (QPOSCTL) and describes the QPOSCTL bit fields.

Figure 34-13. eQEP Position-compare Event Generation Points

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in Figure 34-14.

Figure 34-14. eQEP Position-compare Sync Output Pulse Stretcher

34.2.2.4 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in Figure 34-15. This feature is typically used for low speed measurement using the following equation:

$$v(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (70)$$

where,

- X - Unit position is defined by integer multiple of quadrature edges (see Figure 34-16)
- ΔT - Elapsed time between unit position events
- v(k) - Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled VCLK3 and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS:UPEVNT to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement and clear the flag by writing 1.

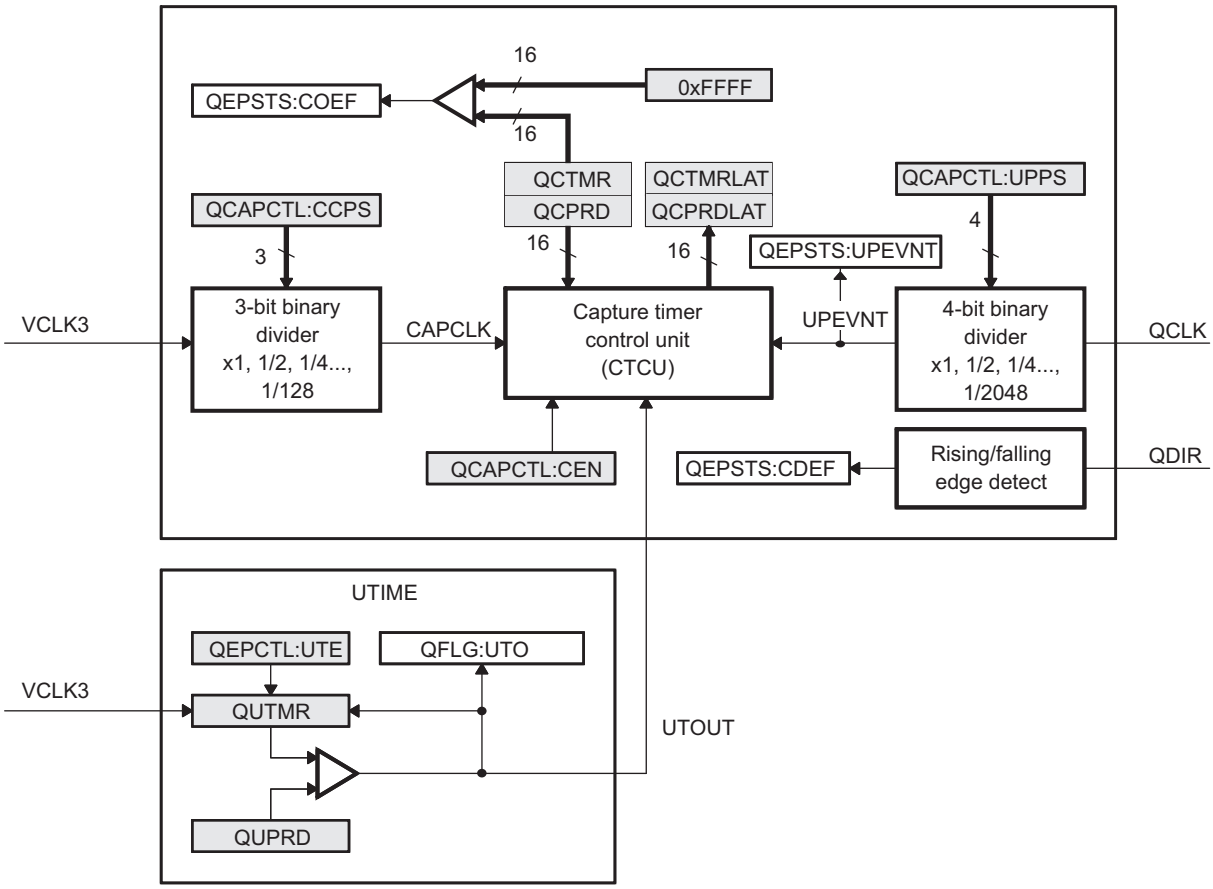
Time measurement (ΔT) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the eQEP overflow error flag (QEPSTS[COEF]) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (QEPSTS[CDEF]).

Capture Timer (QCTMR) and Capture period register (QCPRD) can be configured to latch on following events.

- CPU read of QPOSCNT register
- Unit time-out event



If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

Figure 34-17 shows the capture unit operation along with the position counter.

Figure 34-15. eQEP Edge Capture Unit

NOTE: The QCAPCTL[UPPS] prescaler should not be modified dynamically (such as switching the unit event prescaler from QCLK/4 to QCLK/8). Doing so may result in undefined behavior. The QCAPCTL[CPPS] prescaler can be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLK/4 to SYSCLK/8) only after the capture unit is disabled.

Figure 34-17. eQEP Edge Capture Unit - Timing Details

Velocity Calculation Equations:

$$v(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (71)$$

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k-1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement

t(k): Time instant "k"

t(k-1): Time instant "k-1"

Unit time (T) and unit period(X) are configured using the QUPRD and QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the QPOSLAT and QCPRDLAT registers.

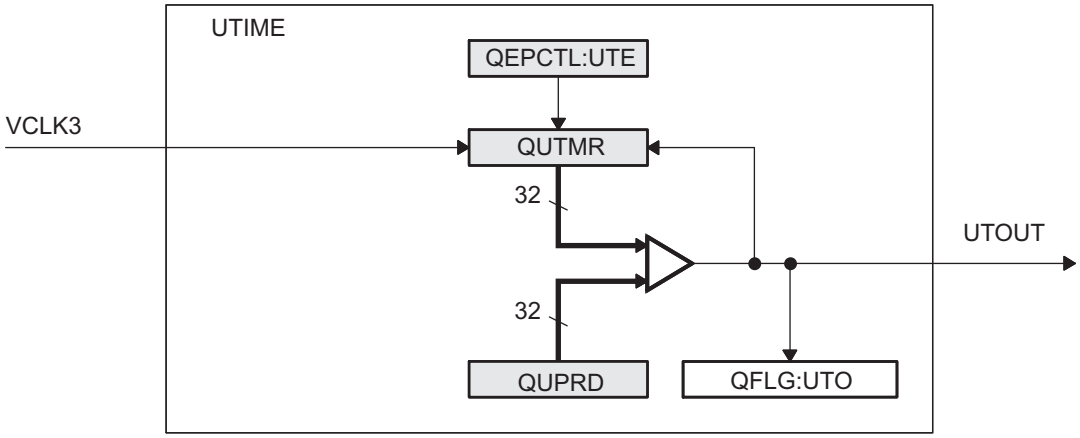
Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (QUPRD)
ΔX	Incremental Position = QPOSLAT(k) - QPOSLAT(K-1)
X	Fixed unit position defined by sensor resolution and ZCAPCTL[UPPS] bits
ΔT	Capture Period Latch (QCPRDLAT)

34.2.3 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from VCLK3/64 and the quadrate clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer will time out and the watchdog interrupt flag will be set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

Figure 34-18. eQEP Watchdog Timer



34.2.4 Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by VCLK3 to generate periodic interrupts for velocity calculations. The unit time out interrupt is set (QFLG[UTO]) when the unit timer (QUTMR) matches the unit period register (QUPRD).

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section 34.2.2.4.

Figure 34-19. eQEP Unit Time Base

34.2.5 eQEP Interrupt Structure

Figure 34-20 shows how the interrupt mechanism works in the EQEP module.

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL and UTO) can be generated. The interrupt control register (QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated only to the PIE if any of the interrupt events is enabled, the flag bit is 1 and the INT flag bit is 0. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register (QCLR), before any other interrupt pulses are generated. You can force an interrupt event by way of the interrupt force register (QFRC), which is useful for test purposes.

Table 34-15. eQEP Control Register (QEPCTL) Field Descriptions (continued)

Bits	Name	Value	Description
6	SEL		Strobe event latch of position counter.
		0	The position counter is latched on the rising edge of QEPS strobe (QPOSSLAT = POSCCNT). Latching on the falling edge can be done by inverting the strobe input using the QSP bit in the QDECCTL register.
		1	Clockwise Direction: Position counter is latched on rising edge of QEPS strobe.
			Counter Clockwise Direction: Position counter is latched on falling edge of QEPS strobe.
5-4	IEL		Index event latch of position counter (software index marker).
		0	Reserved
		1h	Latches position counter on rising edge of the index signal.
		2h	Latches position counter on falling edge of the index signal.
		3h	Software index marker. Latches the position counter and quadrature direction flag on index event marker. The position counter is latched to the QPOSILAT register and the direction flag is latched in the QEPSTS[QDLF] bit. This mode is useful for software index marking.
3	QPEN		Quadrature position counter enable/software reset.
		0	Reset the eQEP peripheral internal operating flags/read-only registers. Control/configuration registers are not disturbed by a software reset.
		1	eQEP position counter is enabled.
2	QCLM		eQEP capture latch mode.
		0	Latch on position counter read by CPU. Capture timer and capture period values are latched into QCTMRLAT and QCPRDLAT registers when CPU reads the QPOSCNT register.
		1	Latch on unit time out. Position counter, capture timer and capture period values are latched into QPOSLAT, QCTMRLAT and QCPRDLAT registers on unit time out.
1	UTE		eQEP unit timer enable.
		0	eQEP unit timer is disabled.
		1	eQEP unit timer is enabled.
0	WDE		eQEP watchdog enable.
		0	eQEP watchdog timer is disabled.
		1	eQEP watchdog timer is enabled.

Enhanced Pulse Width Modulator (ePWM) Module

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipments. The features supported by the ePWM make it especially suitable for digital motor control.

Topic **Page**

35.1 Introduction **1996**
35.2 ePWM Submodules **2000**
35.3 Application Examples **2055**
35.4 ePWM Registers **2070**

Copyright © 2018, Texas Instruments Incorporated

35.1 Introduction

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

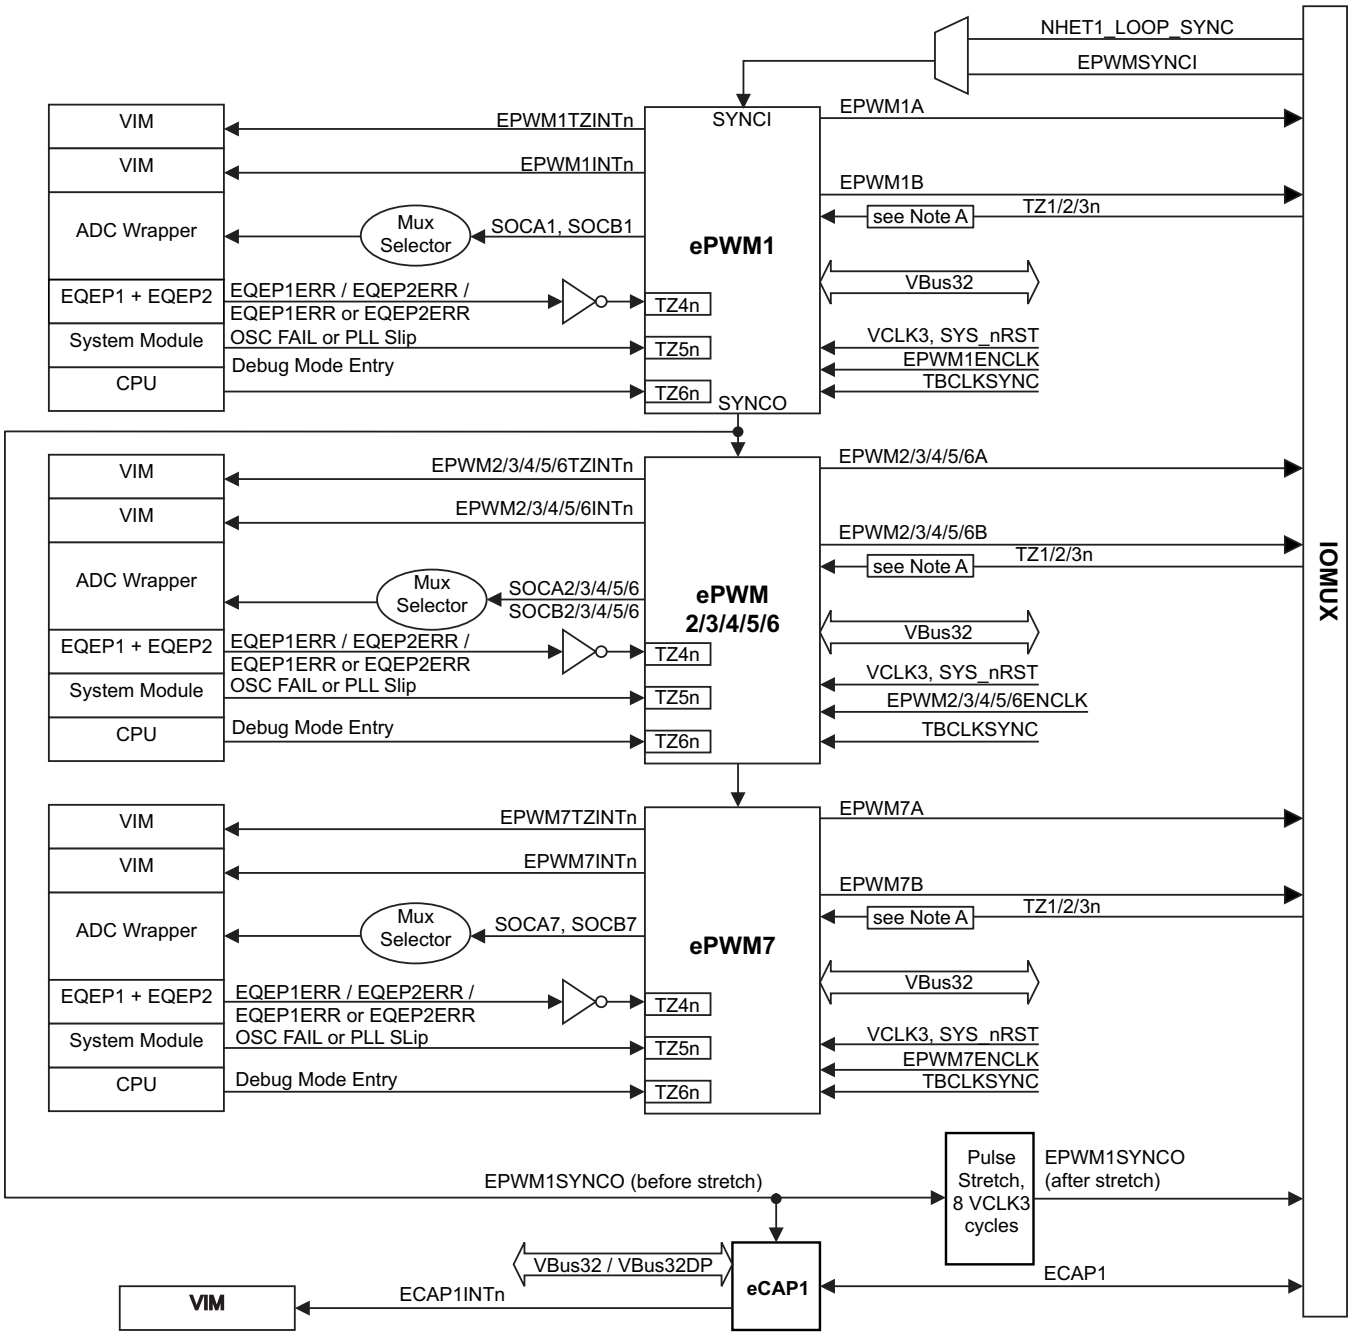
In this document the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

35.1.1 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in Figure 35-1. Each ePWM instance is identical and is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system, and ePWMx indicates any instance.

The ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral modules (eCAP). Modules can also operate stand-alone.

Each ePWM module supports the following features:



- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in Figure 35-1. The signals are described in detail in subsequent sections.

Each ePWM module consists of eight submodules and is connected within a system via the signals shown in Figure 35-2.

Figure 35-1. Multiple ePWM Modules

Copyright © 2018, Texas Instruments Incorporated

Figure 35-2. Submodules and Signal Connections for an ePWM Module

The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).**

  The PWM output signals are made available external to the device through the I/O Multiplexing Module (IOMM) as described in the IOMM chapter.

- **Trip-zone signals ($\overline{TZ1}$ to $\overline{TZ6}$).**

  These input signals alert the ePWM module of fault conditions external to the ePWM module. Each ePWM module can be configured to either use or ignore any of the trip-zone signals. The $\overline{TZ1}$ to $\overline{TZ3}$ trip-zone signals can be configured as asynchronous inputs, or double-synchronized using VCLK3, or double-synchronized and filtered through a 6-VCLK3-cycle counter before connecting to the ePWM modules. This selection is done by configuring registers in the IOMM. $\overline{TZ4}$ is connected to an inverted eQEP1 error signal (EQEP1ERR), or to an inverted eQEP2 error signal (EQEP2ERR), or an OR-combination of EQEP1ERR and EQEP2ERR. This selection is also done via the IOMM registers. $\overline{TZ5}$ is connected to the system clock fail status. This is asserted whenever an oscillator failure is detected, or a PLL slip is detected. $\overline{TZ6}$ is connected to the debug mode entry indicator output from the CPU. This allows you to configure a trip action when the CPU halts.

- **Time-base synchronization input (EPWMxSYNCI) and output (EPWMxSYNCO) signals**.

  The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The synchronization output for ePWM1 (EPWM1SYNCO) is also connected to the SYNCI of the first enhanced capture module (eCAP1).

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).**

  Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the ePWM.

- **Peripheral Bus**

  The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

35.1.2 Register Mapping

The complete ePWM module control and status register set is grouped by submodule as shown in Table 35-1. Each register set is duplicated for each instance of the ePWM module.

Table 35-1. ePWM Module Control and Status Register Set Grouped by Submodule

Name	Address Offset[1]	Size (x16)	Shadow	Privileged Mode Write Only?	Description
Time-Base Submodule Registers					
TBSTS	00h	1	No	No	Time-Base Status Register
TBCTL	02h	1	No	No	Time-Base Control Register

35.2 ePWM Submodules

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

35.2.1 Overview

Table 35-2 lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in Section 35.2.3 for relevant details.

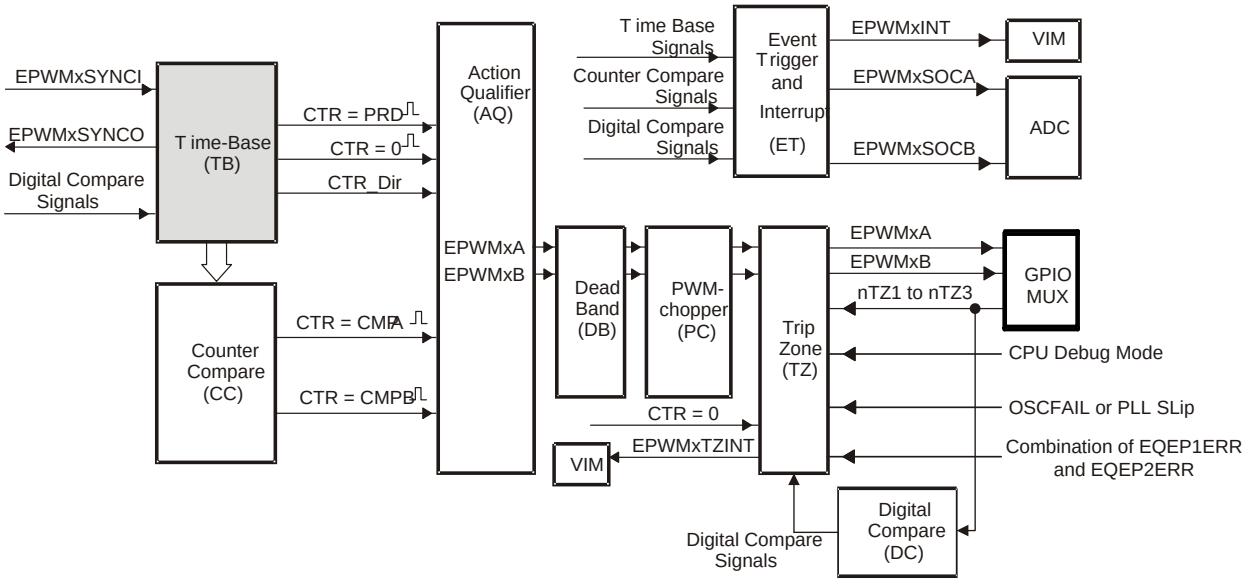
Table 35-2. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time-base (TB)	• Scale the time-base clock (TBCLK) relative to the system clock (VCLK3). • Configure the PWM time-base counter (TBCTR) frequency or period. • Set the mode for the time-base counter: – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Configure how the time-base counter will behave when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module: – Synchronization input signal – Time-base counter equal to zero – Time-base counter equal to counter-compare B (CMPB) – No output synchronization signal generated.
Counter-compare (CC)	• Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB • Specify the time at which switching events occur on the EPWMxA or EPWMxB output
Action-qualifier (AQ)	• Specify the type of action taken when a time-base or counter-compare submodule event occurs: – No action taken – Output EPWMxA and/or EPWMxB switched high – Output EPWMxA and/or EPWMxB switched low – Output EPWMxA and/or EPWMxB toggled • Force the PWM output state through software control • Configure and control the PWM dead-band through software

Copyright © 2018, Texas Instruments Incorporated

Table 35-2. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Dead-band (DB)	• Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification. • Option to enable half-cycle clocking for double resolution.
PWM-chopper (PC)	• Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.
Trip-zone (TZ)	• Configure the ePWM module to react to one, all, or none of the trip-zone signals or digital compare events. • Specify the tripping action taken when a fault occurs: – Force EPWMxA and/or EPWMxB high – Force EPWMxA and/or EPWMxB low – Force EPWMxA and/or EPWMxB to a high-impedance state – Configure EPWMxA and/or EPWMxB to ignore any trip condition. • Configure how often the ePWM will react to each trip-zone signal: – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely.
Event-trigger (ET)	• Enable the ePWM events that will trigger an interrupt. • Enable ePWM events that will trigger an ADC start-of-conversion event. • Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) • Poll, set, or clear event flags
Digital-compare (DC)	• Enables trip zone signals to create events and filtered events • Specify event-filtering options to capture TBCTR counter or generate blanking window



Code examples are provided in this chapter that show how to implement various ePWM module configurations. These examples use the constant definitions in the device *EPwm_defines.h* file in the device-specific header file and peripheral examples software package.

35.2.2 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 35-3 illustrates the time-base module's place within the ePWM.

Figure 35-3. Time-Base Submodule Block Diagram

35.2.2.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000).
- Configure the rate of the time-base clock; a prescaled version of the device peripheral clock domain (VCLK3). This allows the time-base counter to increment/decrement at a slower rate.

35.2.2.2 Controlling and Monitoring the Time-Base Submodule

Table 35-3 shows the registers used to control and monitor the time-base submodule.

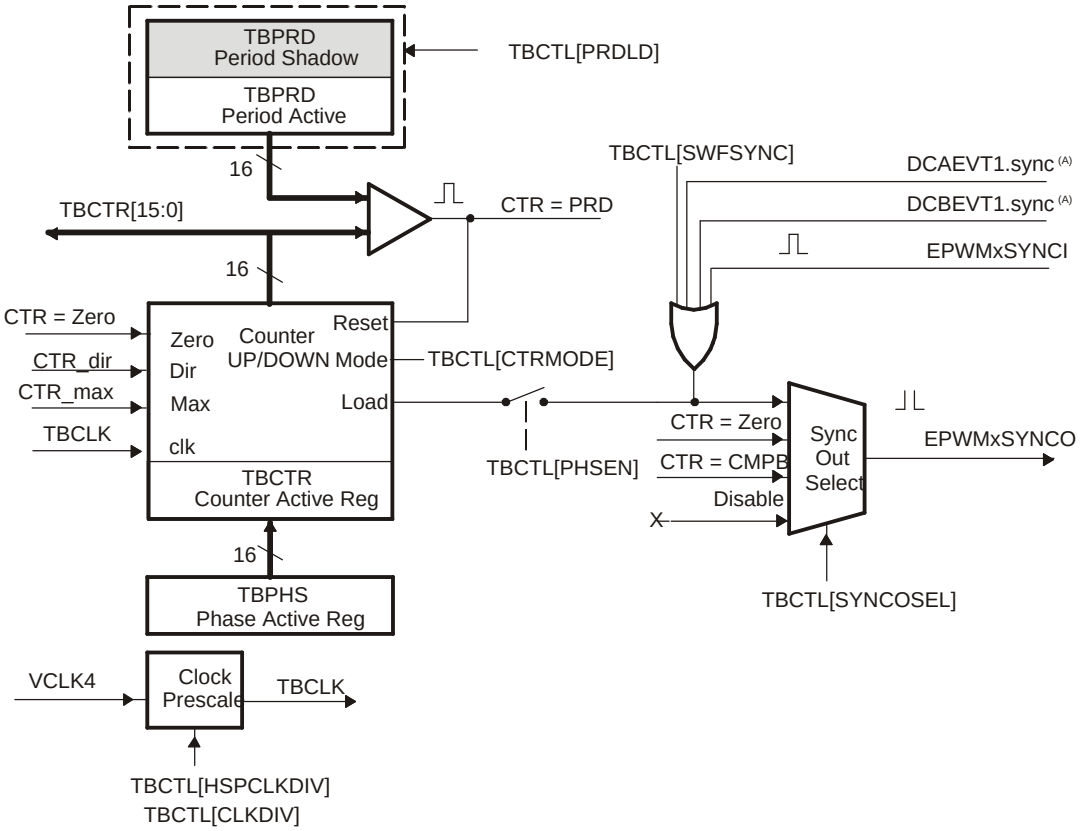

Table 35-3. Time-Base Submodule Registers

Register	Address Offset	Shadowed	Description
TBSTS	00h	No	Time-Base Status Register
TBCTL	02h	No	Time-Base Control Register
TBPHS	04h	No	Time-Base Phase Register
TBPRD	08h	Yes	Time-Base Period Register
TBCTR	0Ah	No	Time-Base Counter Register

Copyright © 2018, Texas Instruments Incorporated

Figure 35-4 shows the critical signals and registers of the time-base submodule. Table 35-4 provides descriptions of the key signals associated with the time-base submodule.

Figure 35-4. Time-Base Submodule Signals and Registers

A. These signals are generated by the digital compare (DC) submodule.

Table 35-4. Key Time-Base Signals

Signal	Description
EPWMxSYNCI	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM1) this signal comes from a device pin or from the N2HET1 module. For subsequent ePWM modules this signal is passed from another ePWM peripheral. For example, EPWM2SYNCI is generated by the ePWM1 peripheral, EPWM3SYNCI is generated by ePWM2 and so forth. See Section 35.2.2.3.3 for information on the synchronization order of a particular device.
EPWMxSYNCO	Time-base synchronization output. This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: 1. EPWMxSYNCI (Synchronization input pulse) 2. CTR = Zero: The time-base counter equal to zero (TBCTR = 0x0000). 3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCTR = CMPB) register.
CTR = PRD	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.
CTR = Zero	Time-base counter equal to zero This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x0000.

Copyright © 2018, Texas Instruments Incorporated

Table 35-4. Key Time-Base Signals (continued)

Signal	Description
CTR = CMPB	Time-base counter equal to active counter-compare B register (TBCTR = CMPB).
	This event is generated by the counter-compare submodule and used by the synchronization out logic
CTR_dir	Time-base counter direction.
	Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CTR_max	Time-base counter equal max value. (TBCTR = 0xFFFF)
	Generated event when the TBCTR value reaches its maximum value. This signal is only used only as a status bit
TBCLK	Time-base clock.
	This is a prescaled version of the system clock (VCLK3) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

35.2.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 35-5 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (VCLK3).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:**

  In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.

- **Up-Count Mode:**

  In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.

- **Down-Count Mode:**

  In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

35.2.2.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register**

  The active register controls the hardware and is responsible for actions that the hardware causes or invokes.

- **Shadow Register**

  The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

Copyright © 2018, Texas Instruments Incorporated

Figure 35-5. Time-Base Frequency and Period

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDLD] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:**

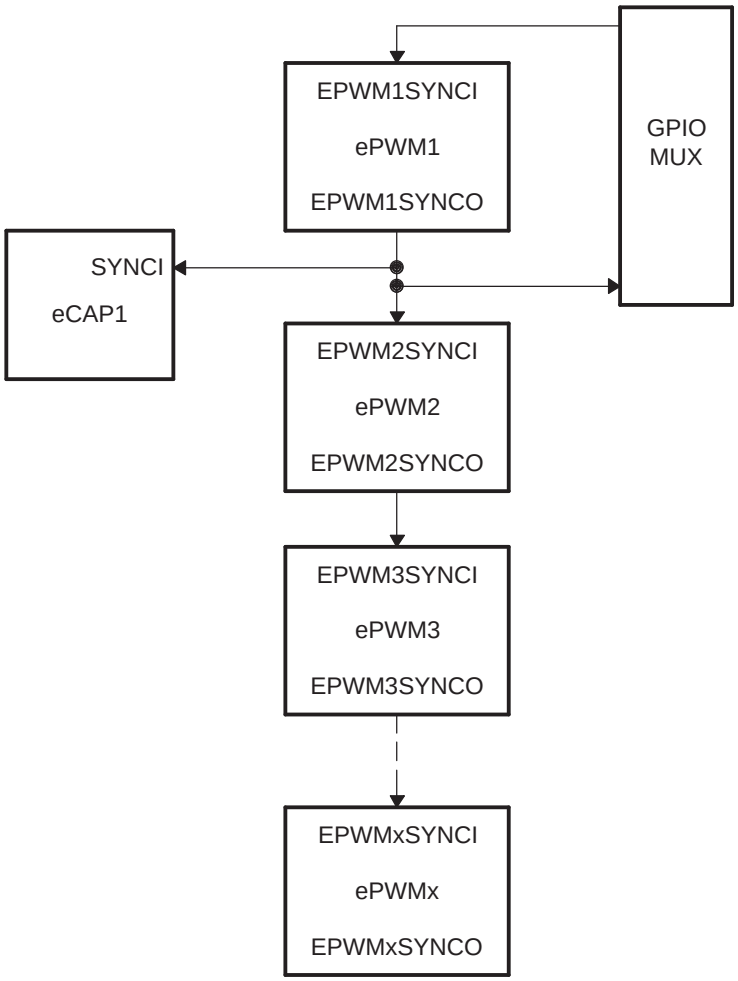
  The TBPRD shadow register is enabled when TBCTL[PRDLD] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x0000). By default the TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:**

  If immediate load mode is selected (TBCTL[PRDLD] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

35.2.2.3.2 Time-Base Clock Synchronization

Bit 1 of the device-level multiplexing control module (IOMM) register PINMMR166 is defined as the TBCLKSYNC bit. The TBCLKSYNC bit allows users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

Copyright © 2018, Texas Instruments Incorporated



The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC = 1.

35.2.2.3.3 Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCI) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM1) comes from an external pin. The synchronization connections for the remaining ePWM modules are shown in Figure 35-6.

Figure 35-6. Time-Base Counter Synchronization Scheme

Copyright © 2018, Texas Instruments Incorporated

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:**

  The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

  The delay from internal master module to slave modules is given by:

  – if (TBCLK = VCLK3): 2 x VCLK3
  – if (TBCLK != VCLK3): 1 TBCLK

- **Software Forced Synchronization Pulse:**

  Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCI.

- **Digital Compare Event Synchronization Pulse:**

  DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCI.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PHSDIR bit is ignored in count-up or count-down modes. See Figure 35-7 through Figure 35-10 for examples.

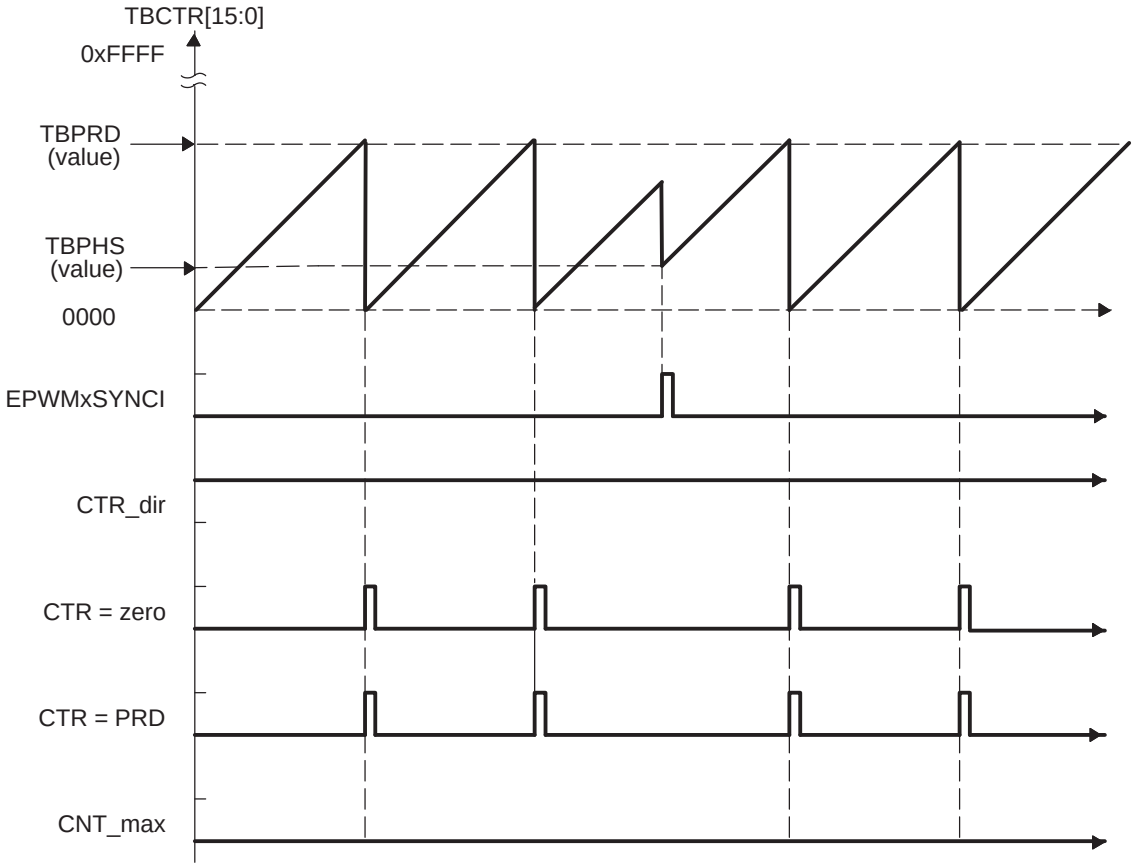
Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master.

35.2.2.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC= 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC=1.

35.2.2.5 Time-base Counter Modes and Timing Waveforms



The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

35.2.3 Counter-Compare (CC) Submodule

Figure 35-11 illustrates the counter-compare submodule within the ePWM.

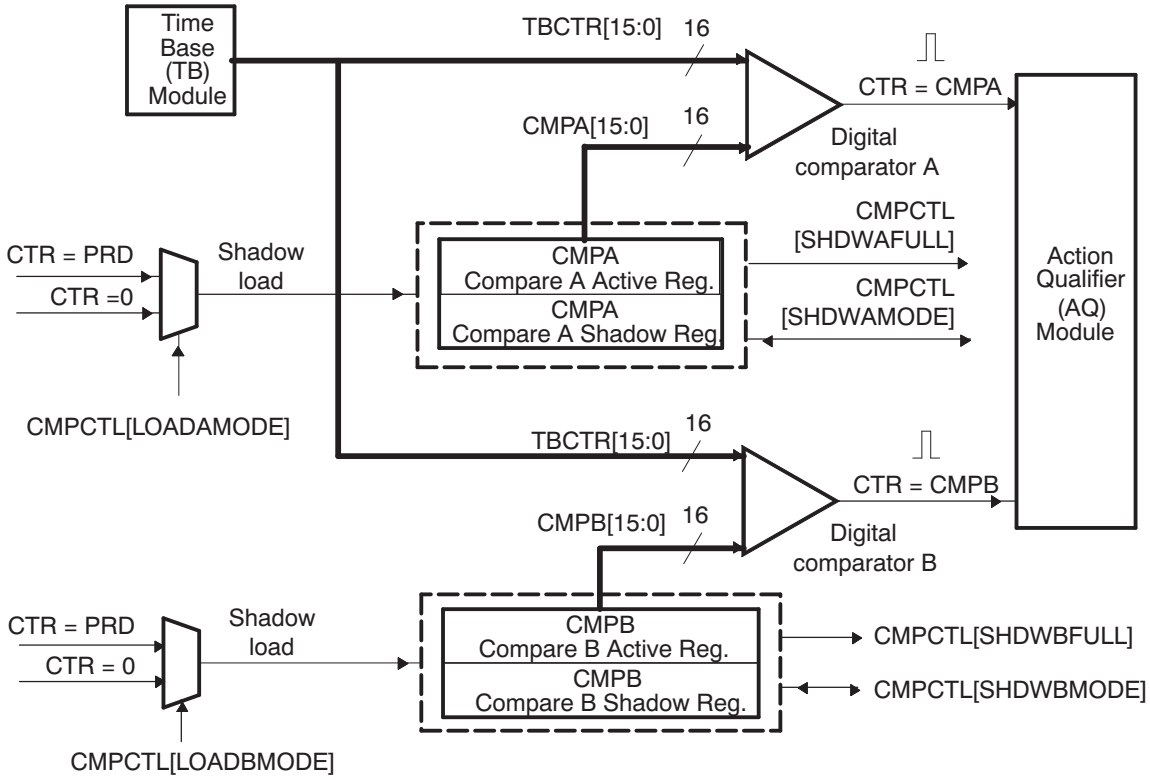

Figure 35-12 shows the basic structure of the counter-compare submodule.

Figure 35-11. Counter-Compare Submodule

Copyright © 2018, Texas Instruments Incorporated

Figure 35-12. Detailed View of the Counter-Compare Submodule

35.2.3.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA) and counter-compare B (CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA and CMPB registers
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA).
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

35.2.3.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is controlled and monitored by the registers listed in Table 35-5.

The key signals associated with the counter-compare submodule are described in Table 35-6.

Table 35-5. Counter-Compare Submodule Registers

Register Name	Address Offset	Shadowed	Description
CMPCTL	0Ch	No	Counter-Compare Control Register.
CMPA	10h	Yes	Counter-Compare A Register
CMPB	16h	Yes	Counter-Compare B Register

Copyright © 2018, Texas Instruments Incorporated

Table 35-6. Counter-Compare Submodule Key Signals

Signal	Description of Event	Registers Compared
CTR = CMPA	Time-base counter equal to the active counter-compare A value	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the active counter-compare B value	TBCTR = CMPB
CTR = PRD	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCTR = TBPRD
CTR = ZERO	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCTR = 0x0000

35.2.3.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle if the compare value is between 0x0000-TBPRD and once per cycle if the compare value is equal to 0x0000 or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to Section 35.2.4.1 for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is described below:

Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE] and CMPCTL[LOADBMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
- Both CTR = PRD and CTR = Zero

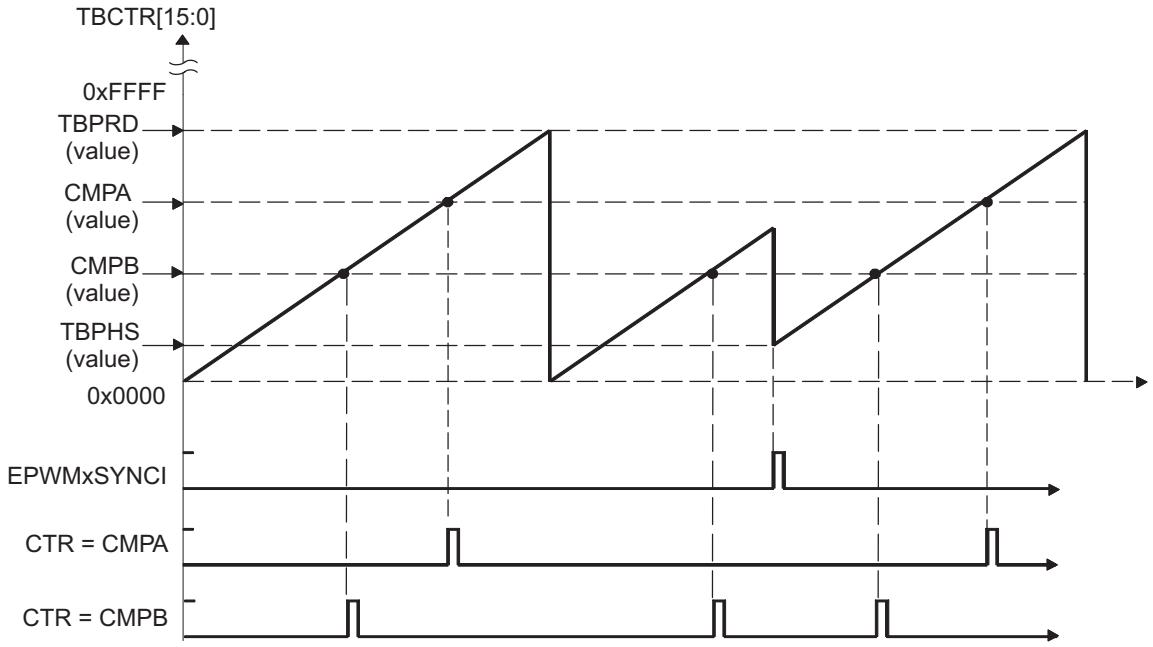
Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Immediate Load Mode:

If immediate load mode is selected (TBCTL[SHADWAMODE] = 1 or TBCTL[SHADWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

35.2.3.4 Count Mode Timing Waveforms

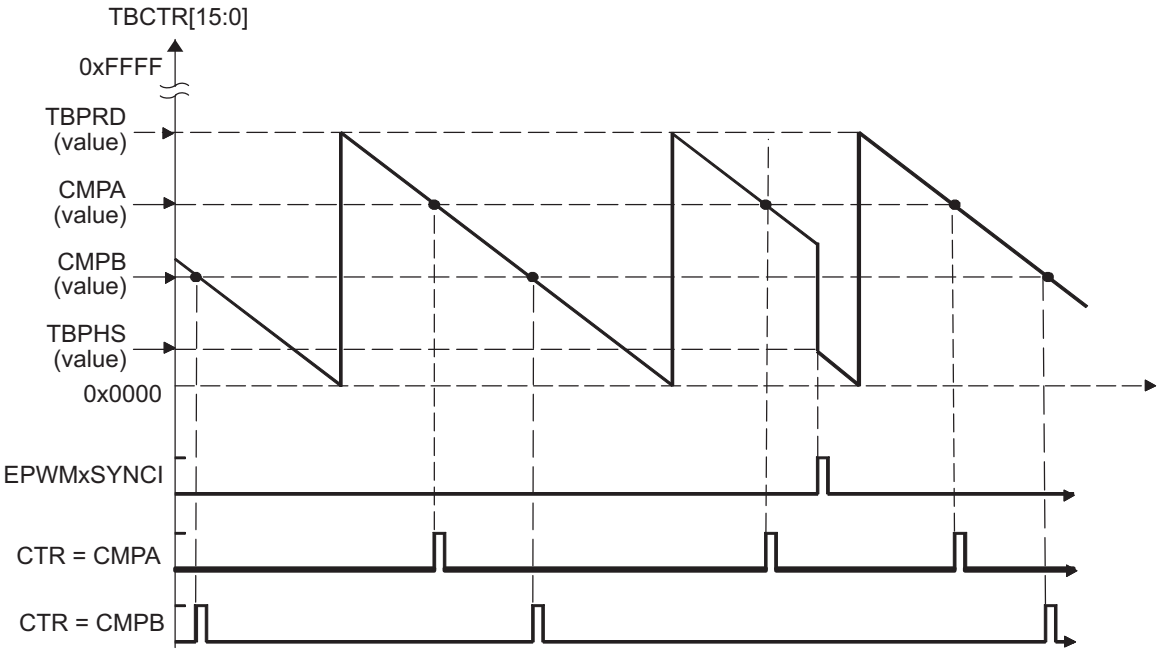
The counter-compare module can generate compare events in all three count modes:



- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.

Copyright © 2018, Texas Instruments Incorporated

- Up-down-count mode: used to generate a symmetrical PWM waveform.



To illustrate the operation of the first three modes, the timing diagrams in Figure 35-13 through Figure 35-16 show when events are generated and how the EPWMxSYNCI signal interacts.

Figure 35-13. Counter-Compare Event Waveforms in Up-Count Mode

NOTE: An EPWMxSYNCI external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

35.2.4 Action-Qualifier (AQ) Submodule

Figure 35-17 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system.

The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 35-17. Action-Qualifier Submodule

35.2.4.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing.

35.2.4.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is controlled and monitored via the registers in Table 35-7.

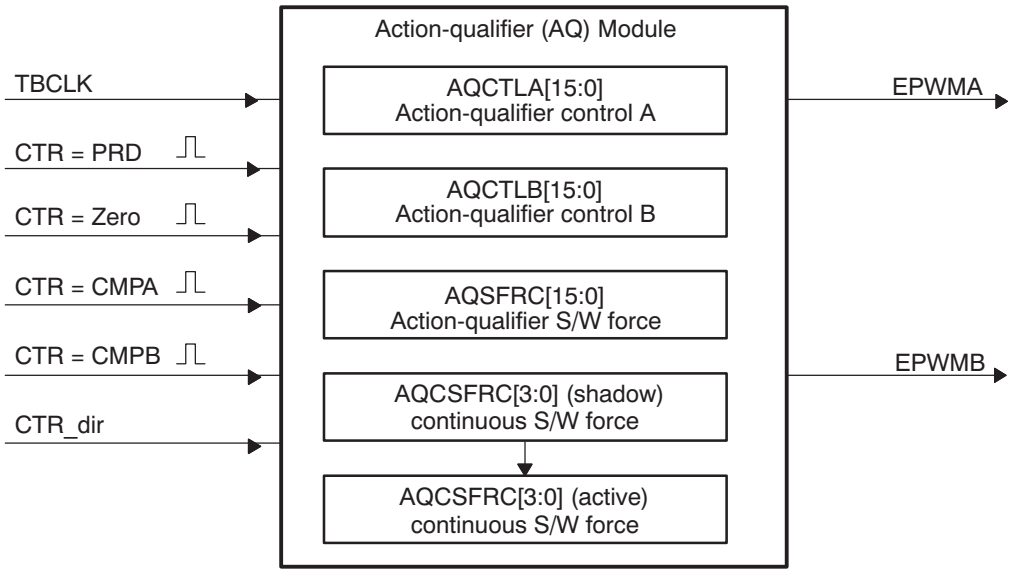

Table 35-7. Action-Qualifier Submodule Registers

Register Name	Address Offset	Shadowed	Description
AQCTLA	14h	No	Action-Qualifier Control Register For Output A (EPWMxA)
AQSFRC	18h	No	Action-Qualifier Software Force Register
AQCTLB	1Ah	No	Action-Qualifier Control Register For Output B (EPWMxB)
AQCSFRC	1Eh	Yes	Action-Qualifier Continuous Software Force

Copyright © 2018, Texas Instruments Incorporated

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in Table 35-7.

Figure 35-18. Action-Qualifier Submodule Inputs and Outputs

The possible input events are summarized again in Table 35-8.

Table 35-8. Action-Qualifier Submodule Possible Input Events

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCTR = TBPRD
CTR = Zero	Time-base counter equal to zero	TBCTR = 0x0000
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCTR = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by registers AQSFRC and AQCSFRC.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:**

  Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:**

  Set output EPWMxA or EPWMxB to a low level.
- **Toggle:**

  If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.

Copyright © 2018, Texas Instruments Incorporated

- **Do Nothing:**

  Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the Event-trigger Submodule description in Section 35.2.8 for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this document use a set of symbolic actions. These symbols are summarized in Figure 35-19. Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

Figure 35-19. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
SW ✕	Z ✕	CA ✕	CB ✕	P ✕	Do Nothing
SW ↓	Z ↓	CA ↓	CB ↓	P ↓	Clear Low
SW ↑	Z ↑	CA ↑	CB ↑	P ↑	Set High
SW T	Z T	CA T	CB T	P T	Toggle

35.2.4.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in Table 35-9. A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCTR.

Table 35-9. Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD	Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD)
5	Counter equals CMPB on down-count (CBD)	Counter equals CMPB on up-count (CBU)
6 (Lowest)	Counter equals CMPA on down-count (CAD)	Counter equals CMPA on up-count (CBU)

Table 35-10 shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

Table 35-10. Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

Table 35-11 shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

Table 35-11. Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in Table 35-12.

Table 35-12. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAD/CBD	Compare on Down-Count Event CAD/CBD
Up-Count Mode	If CMPA/CMPB ≤ TBPRD period, then the event occurs on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB > TBPRD, then the event will not occur.	Never occurs.

Copyright © 2018, Texas Instruments Incorporated

Table 35-12. Behavior if CMPA/CMPB is Greater than the Period (continued)

Counter Mode	Compare on Up-Count Event CAD/CBD	Compare on Down-Count Event CAD/CBD
Down-Count Mode	Never occurs.	If CMPA/CMPB < TBPRD, the event will occur on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event will occur on a period match (TBCTR=TBPRD).
Up-Down-Count Mode	If CMPA/CMPB < TBPRD and the counter is incrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB is ≥ TBPRD, the event will occur on a period match (TBCTR = TBPRD).	If CMPA/CMPB < TBPRD and the counter is decrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCTR=TBPRD).

35.2.4.4 Waveforms for Common Configurations

NOTE: The waveforms in this document show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down-count mode to generate a symmetric PWM:

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1.

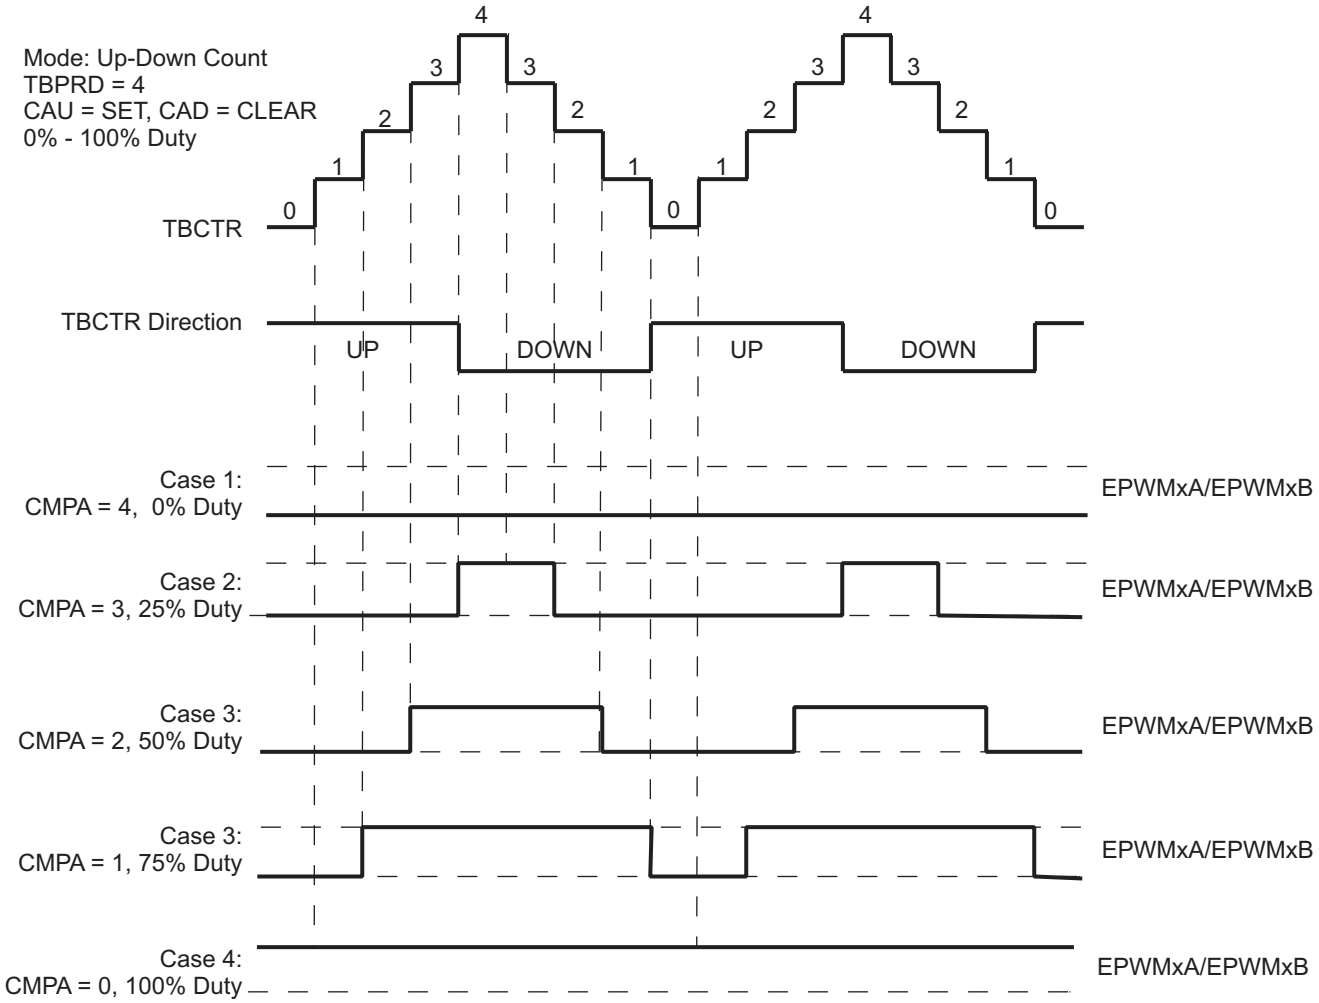
  This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.



See the *Using Enhanced Pulse Width Modulator (ePWM) Module for 0-100% Duty Cycle Control* Application Report (literature number SPRAAI1)

Figure 35-20 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When CMPA = 0, the PWM signal is low for the entire period giving the 0% duty waveform. When CMPA = TBPRD, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

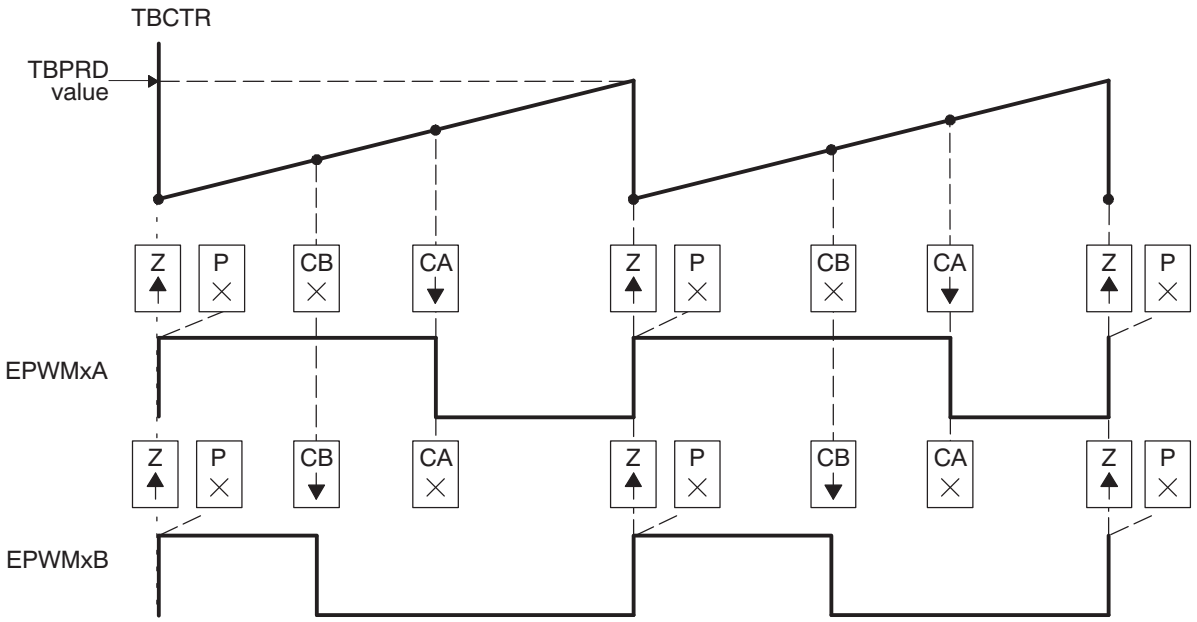
Figure 35-20. Up-Down-Count Mode Symmetrical Waveform



The PWM waveforms in Figure 35-21 through Figure 35-26 show some common action-qualifier configurations. The C-code samples in Example 35-1 through Example 35-6 shows how to configure an ePWM module for each case. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

Example 35-1 contains a code sample showing initialization and run time for the waveforms in Figure 35-21.

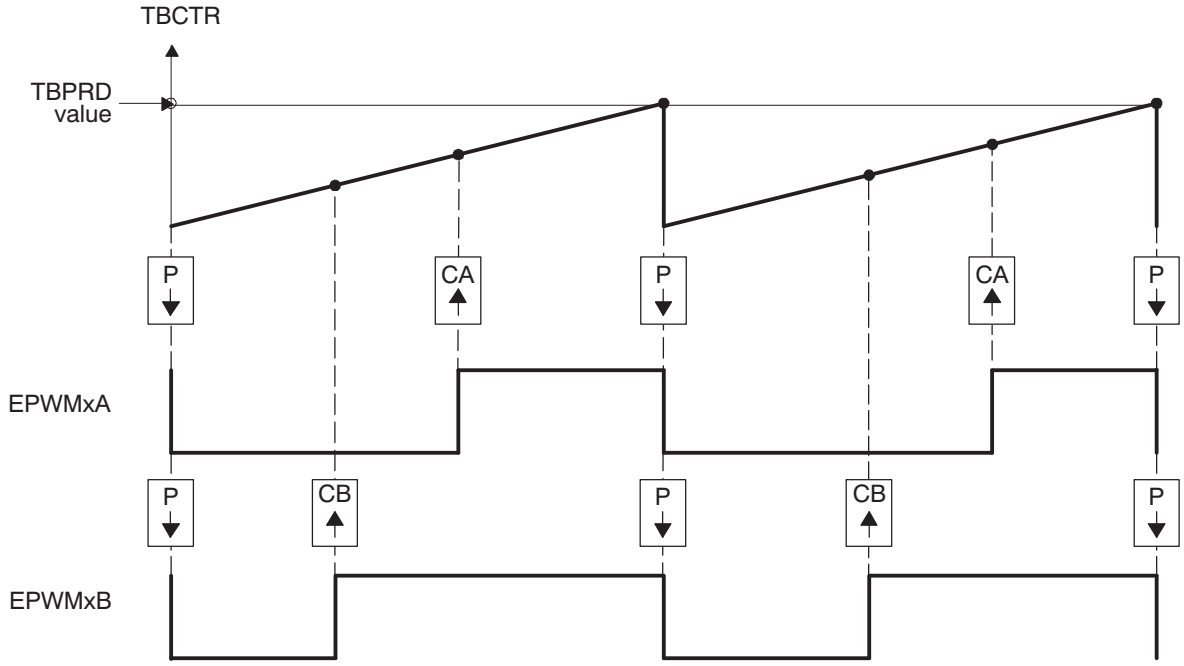
Figure 35-21. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High

A PWM period = (TBPRD + 1) × T_{TBCLK}

B Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).

C Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).

D The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.



E Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

35.2.5 Dead-Band Generator (DB) Submodule

Figure 35-27 illustrates the dead-band submodule within the ePWM module.

Figure 35-27. Dead_Band Submodule

35.2.5.1 Purpose of the Dead-Band Submodule

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band submodule described here should be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

35.2.5.2 Controlling and Monitoring the Dead-Band Submodule

The dead-band submodule operation is controlled and monitored via the following registers:

Table 35-13. Dead-Band Generator Submodule Registers

Register Name	Address Offset	Shadowed	Description
DBCTL	1Ch	No	Dead-Band Control Register
DBFED	20h	No	Dead-Band Falling Edge Delay Count Register
DBRED	22h	No	Dead-Band Rising Edge Delay Count Register

Copyright © 2018, Texas Instruments Incorporated

35.2.5.3 Operational Highlights for the Dead-Band Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in Figure 35-28.

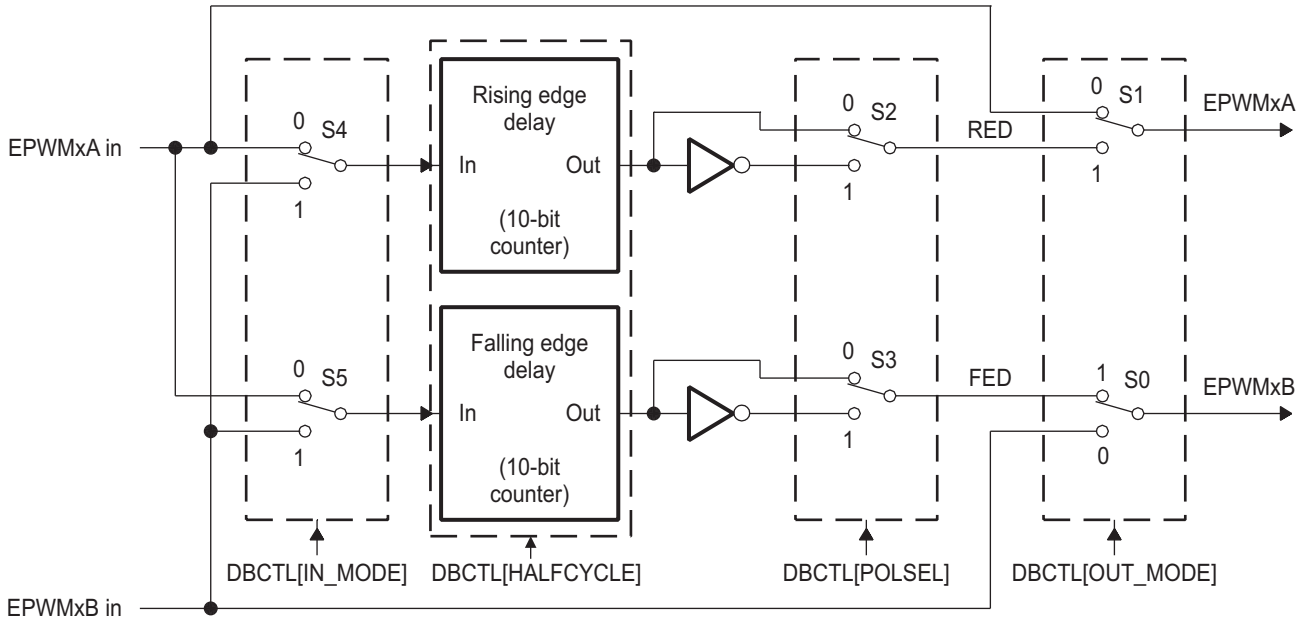
- **Input Source Selection:**

  The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the DBCTL[IN_MODE) control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:

  – EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  – EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  – EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  – EPWMxB In is the source for both falling-edge and rising-edge delay.

- **Half Cycle Clocking:**

  The dead-band submodule can be clocked using half cycle clocking to double the resolution (i.e. counter clocked at 2× TBCLK)



- **Output Mode Control:**

  The output mode is configured by way of the DBCTL[OUT_MODE] bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.

- **Polarity Control:**

  The polarity control (DBCTL[POLSEL]) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

Figure 35-28. Configuration Options for the Dead-Band Submodule

Copyright © 2018, Texas Instruments Incorporated

Although all combinations are supported, not all are typical usage modes. Table 35-14 documents some classical dead-band configurations. These modes assume that the DBCTL[IN_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 35-14 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)**

  Allows you to fully disable the dead-band submodule from the PWM signal path.

- **Mode 2-5: Classical Dead-Band Polarity Settings:**

  These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 35-29. Note that to generate equivalent waveforms to Figure 35-29, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.

- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay**

  Finally the last two entries in Table 35-14 show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

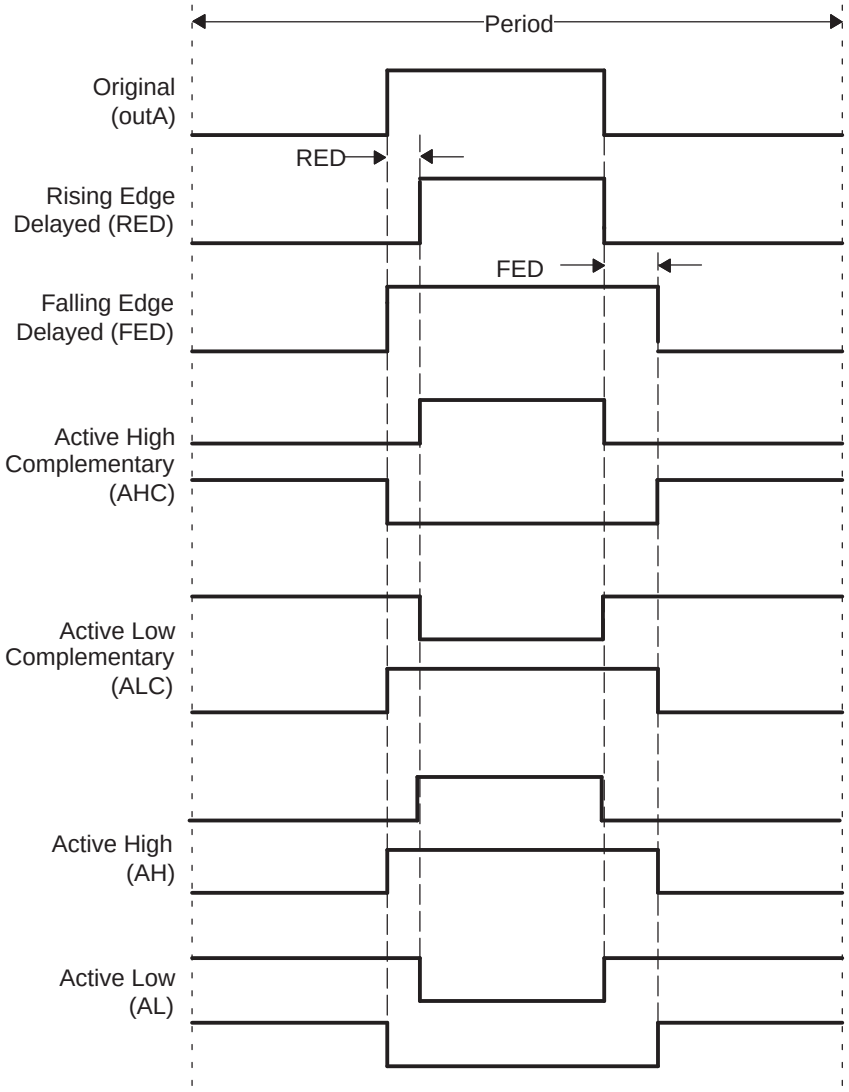


Table 35-14. Classical Dead-Band Operating Modes

		DBCTL[POLSEL]		DBCTL[OUT_MODE]	
Mode	**Mode Description**	**S3**	**S2**	**S1**	**S0**
1	EPWMxA and EPWMxB Passed Through (No Delay)	X	X	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

Figure 35-29 shows waveforms for typical cases where 0% < duty < 100%.

Figure 35-29. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)

Copyright © 2018, Texas Instruments Incorporated

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

$FED = DBFED \times T_{TBCLK}$

$RED = DBRED \times T_{TBCLK}$

Where T_{TBCLK} is the period of TBCLK, the prescaled version of VCLK3.

For convenience, delay values for various TBCLK options are shown in Table 35-15.

Table 35-15. Dead-Band Delay Values in μS as a Function of DBFED and DBRED

Dead-Band Value	Dead-Band Delay in μS		
DBFED, DBRED	TBCLK = VCLK3/1	TBCLK = VCLK3 /2	TBCLK = VCLK3/4
1	0.02 μS	0.03 μS	0.07 μS
5	0.08 μS	0.17 μS	0.33 μS
10	0.17 μS	0.33 μS	0.67 μS
100	1.67 μS	3.33 μS	6.67 μS
200	3.33 μS	6.67 μS	13.33 μS
400	6.67 μS	13.33 μS	26.67 μS
500	8.33 μS	16.67 μS	33.33 μS
600	10.00 μS	20.00 μS	40.00 μS
700	11.67 μS	23.33 μS	46.67 μS
800	13.33 μS	26.67 μS	53.33 μS
900	15.00 μS	30.00 μS	60.00 μS
1000	16.67 μS	33.33 μS	66.67 μS

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$FED = DBFED \times T_{TBCLK}/2$

$RED = DBRED \times T_{TBCLK}/2$

35.2.6 PWM-Chopper (PC) Submodule

Figure 35-30 illustrates the PWM-chopper (PC) submodule within the ePWM module.

The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

Figure 35-30. PWM-Chopper Submodule

35.2.6.1 Purpose of the PWM-Chopper Submodule

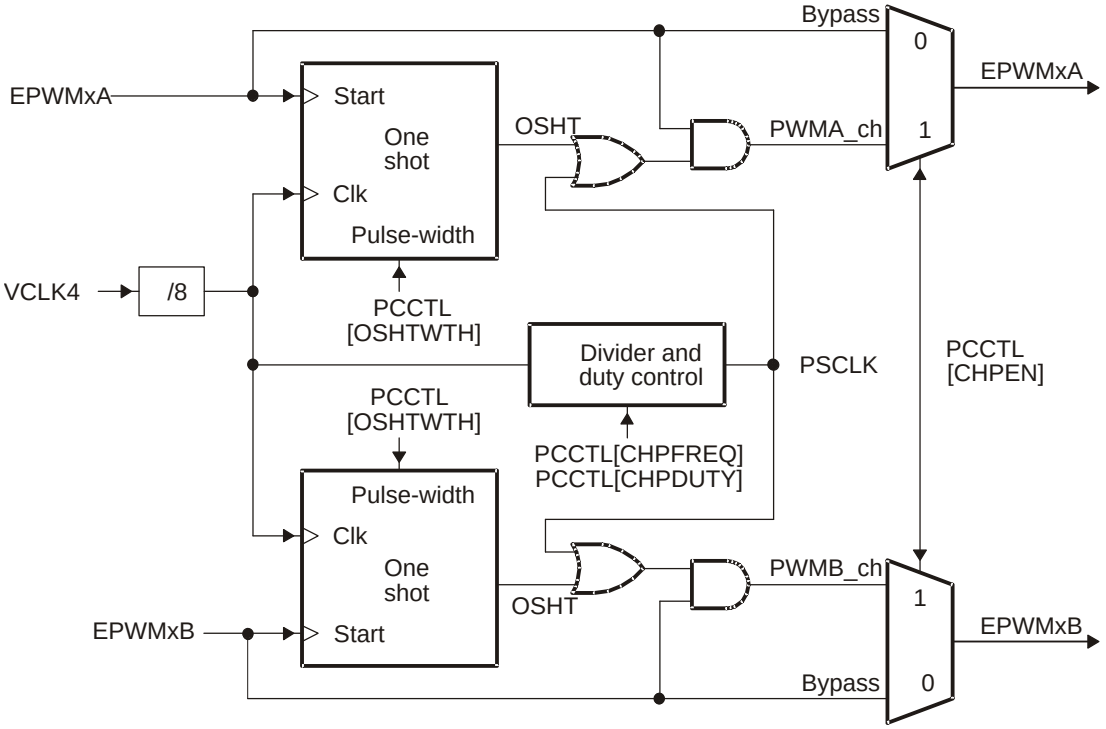
The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

35.2.6.2 Controlling the PWM-Chopper Submodule

The PWM-chopper submodule operation is controlled via the registers in Table 35-16.

Table 35-16. PWM-Chopper Submodule Registers



Register Name	Address Offset	Shadowed	Description
PCCTL	3Eh	No	PWM-chopper Control Register

35.2.6.3 Operational Highlights for the PWM-Chopper Submodule

Figure 35-31 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from VCLK3. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

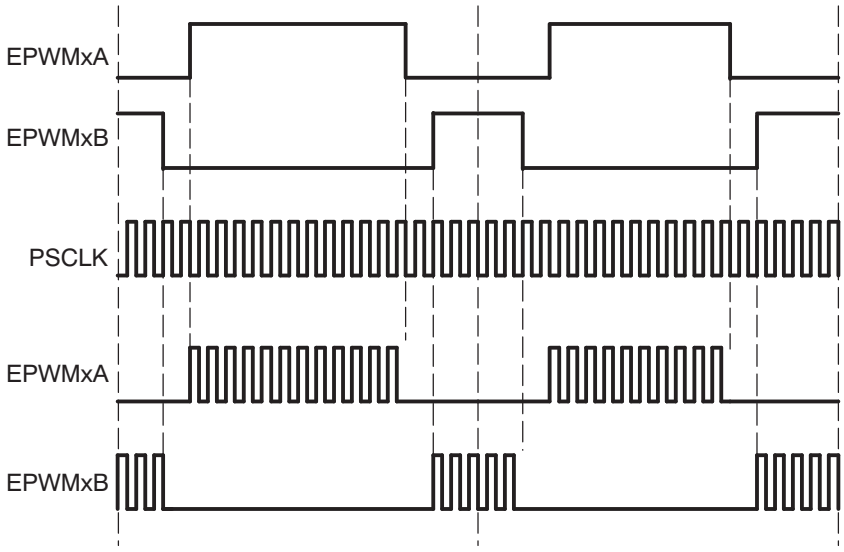

Figure 35-31. PWM-Chopper Submodule Operational Details

35.2.6.4 Waveforms

Figure 35-32 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 35-32. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only

Copyright © 2018, Texas Instruments Incorporated

35.2.6.4.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$T_{1stpulse} = T_{VCLK3} \times 8 \times OSHTWTH$

Where T_{VCLK3} is the period of the system clock (VCLK3) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 35-33 shows the first and subsequent sustaining pulses and Table 35-17 gives the possible pulse width values for a VCLK3 = 100 MHz.

Figure 35-33. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

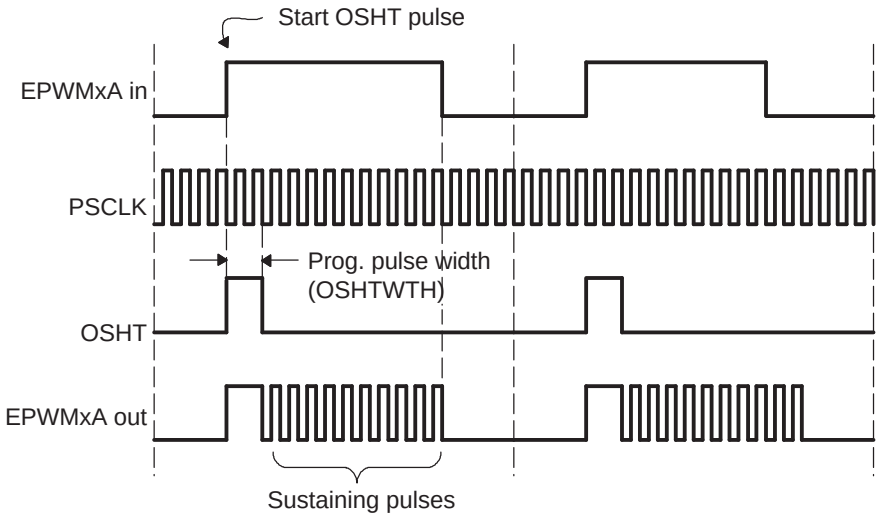

Table 35-17. Possible Pulse Width Values for VCLK3 = 100 MHz

OSHTWTHz (hex)	Pulse Width (nS)
0	100
1	200
2	300

35.2.6.4.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 35-34 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

Figure 35-34. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

35.2.7 Trip-Zone (TZ) Submodule

Figure 35-35 shows how the trip-zone (TZ) submodule fits within the ePWM module.

Each ePWM module is connected to six $\overline{TZn}$ signals ($\overline{TZ1}$ to $\overline{TZ6}$). $\overline{TZ1}$ to $\overline{TZ3}$ are sourced from the GPIO mux. $\overline{TZ4}$ is sourced from a combination of EQEP1ERR and EQEP2ERR signals. $\overline{TZ5}$ is connected to the system oscillator or PLL clock fail logic, and $\overline{TZ6}$ is sourced from the debug mode halt indication output from the CPU. These signals indicate fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

Figure 35-35. Trip-Zone Submodule

35.2.7.1 Purpose of the Trip-Zone Submodule

The key functions of the Trip-Zone submodule are:

- Trip inputs $\overline{TZ1}$ to $\overline{TZ6}$ are mapped to all ePWM modules.
- Upon a fault indication, either no action is taken or the ePWM outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and/or $\overline{TZ1}$ to $\overline{TZ3}$ signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

Copyright © 2018, Texas Instruments Incorporated

35.2.7.2 Controlling and Monitoring the Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

Table 35-18. Trip-Zone Submodule Registers

Register Name	Address Offset	Shadowed	Description [1]
TZDCSEL	24h	No	Trip-zone Digital Compare Select Register [2]
TZSEL	26h	No	Trip-Zone Select Register
TZEINT	28h	No	Trip-Zone Enable Interrupt Register
TZCTL	2Ah	No	Trip-Zone Control Register
TZCLR	2Ch	No	Trip-Zone Clear Register
TZFLG	2Eh	No	Trip-Zone Flag Register
TZFRC	32h	No	Trip-Zone Force Register

(1) All trip-zone registers are writable only in privileged mode.
(2) This register is discussed in more detail in Section 35.2.9.

35.2.7.3 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals $\overline{TZ1}$ to $\overline{TZ6}$ (also collectively referred to as $\overline{TZn}$) are active low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals may or may not be synchronized to the system clock (VCLK3) and digitally filtered within the GPIO MUX block. A minimum of 3 × TBCLK low pulse width on $\overline{TZn}$ inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition may not be latched. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on $\overline{TZn}$ inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the IOMM chapter of the device technical reference manual.

Each $\overline{TZn}$ input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAVET2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input) respectively.

- **Cycle-by-Cycle (CBC):**

  When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. Table 35-19 lists the possible actions. In addition, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

  If the CBC interrupt is enabled via the TZEINT register, and DCAEVT2 or DCBEVT2 are selected as CBC trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

  The specified condition on the inputs is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x0000) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] flag bit will remain set until it is manually cleared by writing to the TZCLR[CBC] bit. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] bit is cleared, then it will again be immediately set.

Copyright © 2018, Texas Instruments Incorporated

- **One-Shot (OSHT):**

  When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. Table 35-19 lists the possible actions. In addition, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit.

  If the one-shot interrupt is enabled via the TZEINT register, and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

  A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected via the DCTRIPSEL register and can be either trip zone input pins. For more information on the digital compare submodule signals, see Section 35.2.9.

  When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and/or EPWMxB output. Table 35-19 lists the possible actions. In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

  The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit will remain set until it is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then it will again be immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL register bit fields. One of four possible actions, shown in Table 35-19, can be taken on a trip event.

Table 35-19. Possible Actions On a Trip Event

TZCTL Register bit-field Settings	EPWMxA and/or EPWMxB	Comment
0,0	High-Impedance	Tripped
0,1	Force to High State	Tripped
1,0	Force to Low State	Tripped
1,1	No Change	Do Nothing. No change is made to the output.

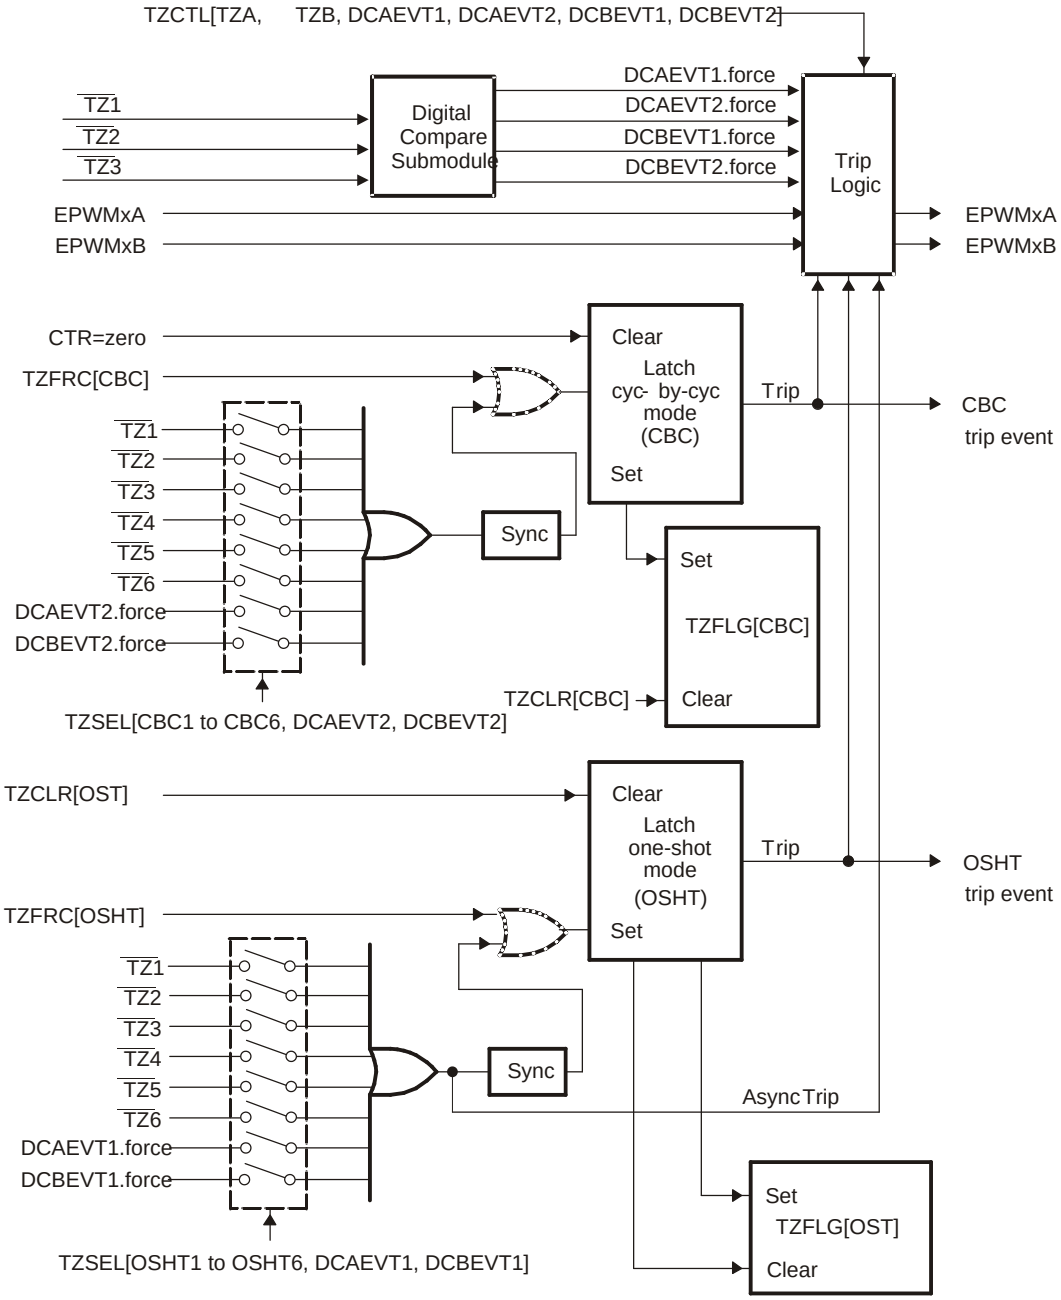
Copyright © 2018, Texas Instruments Incorporated

Example 35-7. Trip-Zone Configurations

Scenario A:
A one-shot trip event on $\overline{TZ1}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

Scenario B:
A cycle-by-cycle event on $\overline{TZ5}$ pulls both EPWM1A, EPWM1B low.
A one-shot event on $\overline{TZ1}$ or $\overline{TZ6}$ puts EPWM2A into a high impedance state.



- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables $\overline{TZ5}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables $\overline{TZ6}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A will be put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B will ignore the trip event.

35.2.7.4 Generating Trip Event Interrupts

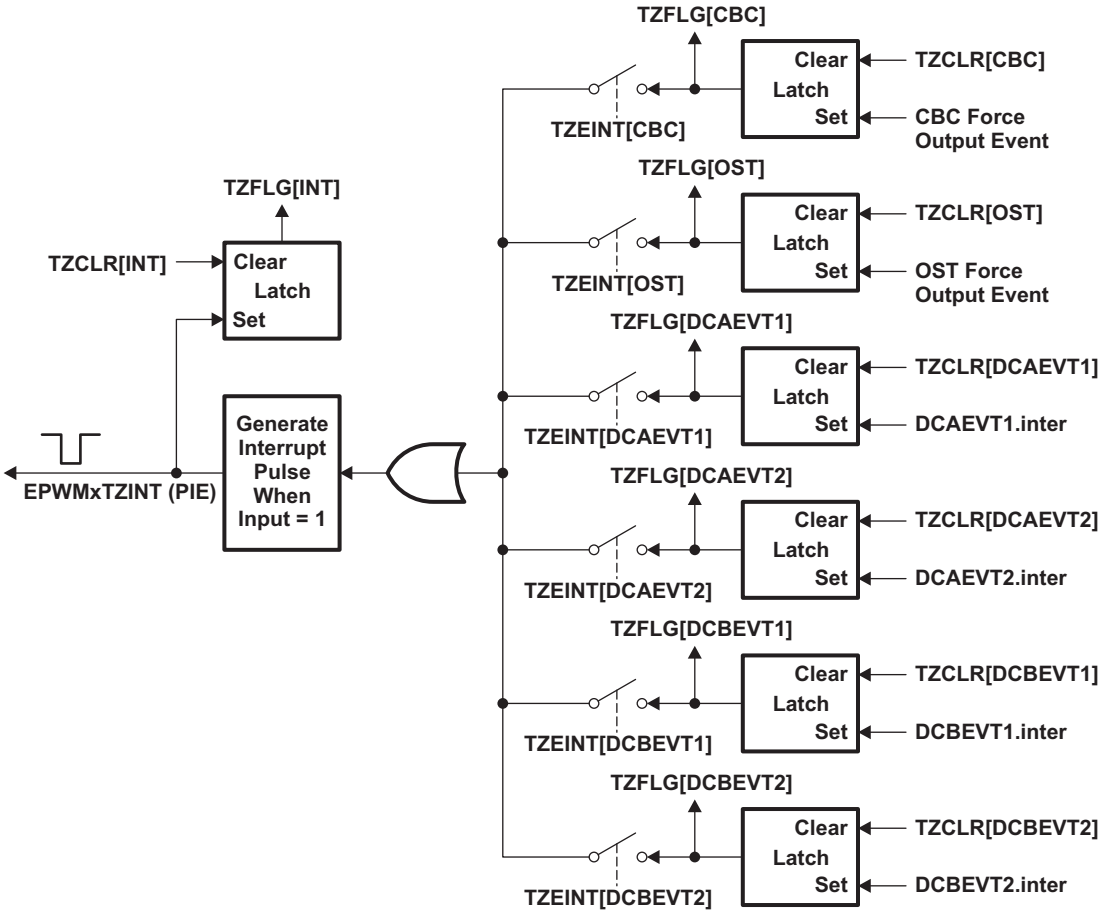

Figure 35-36 and Figure 35-37 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 35.2.9.

Figure 35-36. Trip-Zone Submodule Mode Control Logic

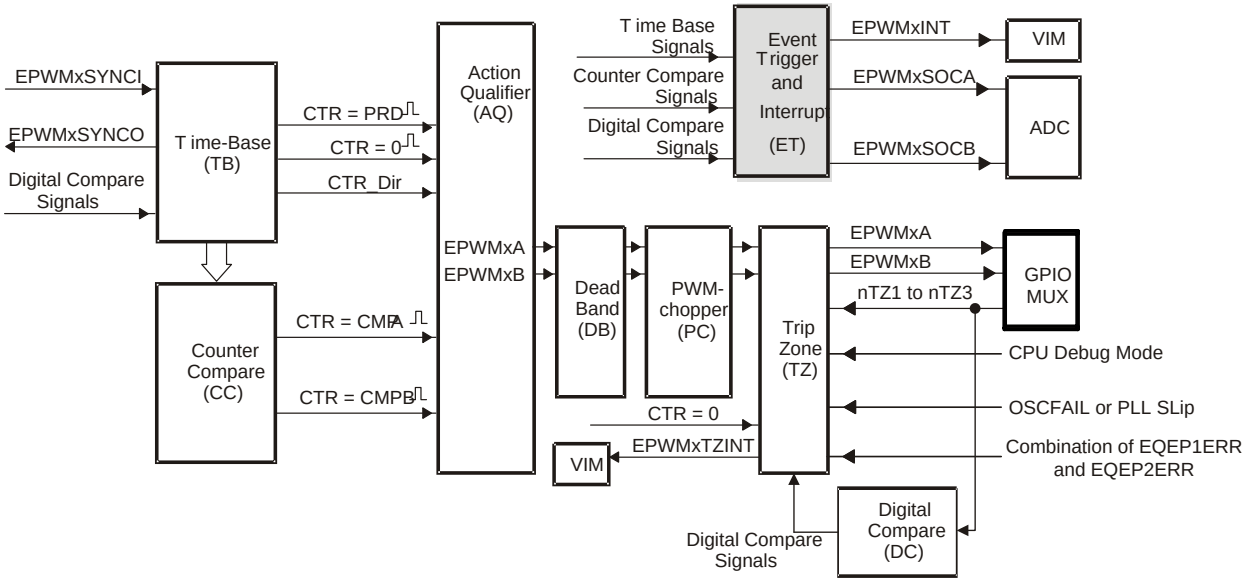
Figure 35-37. Trip-Zone Submodule Interrupt Logic

Copyright © 2018, Texas Instruments Incorporated



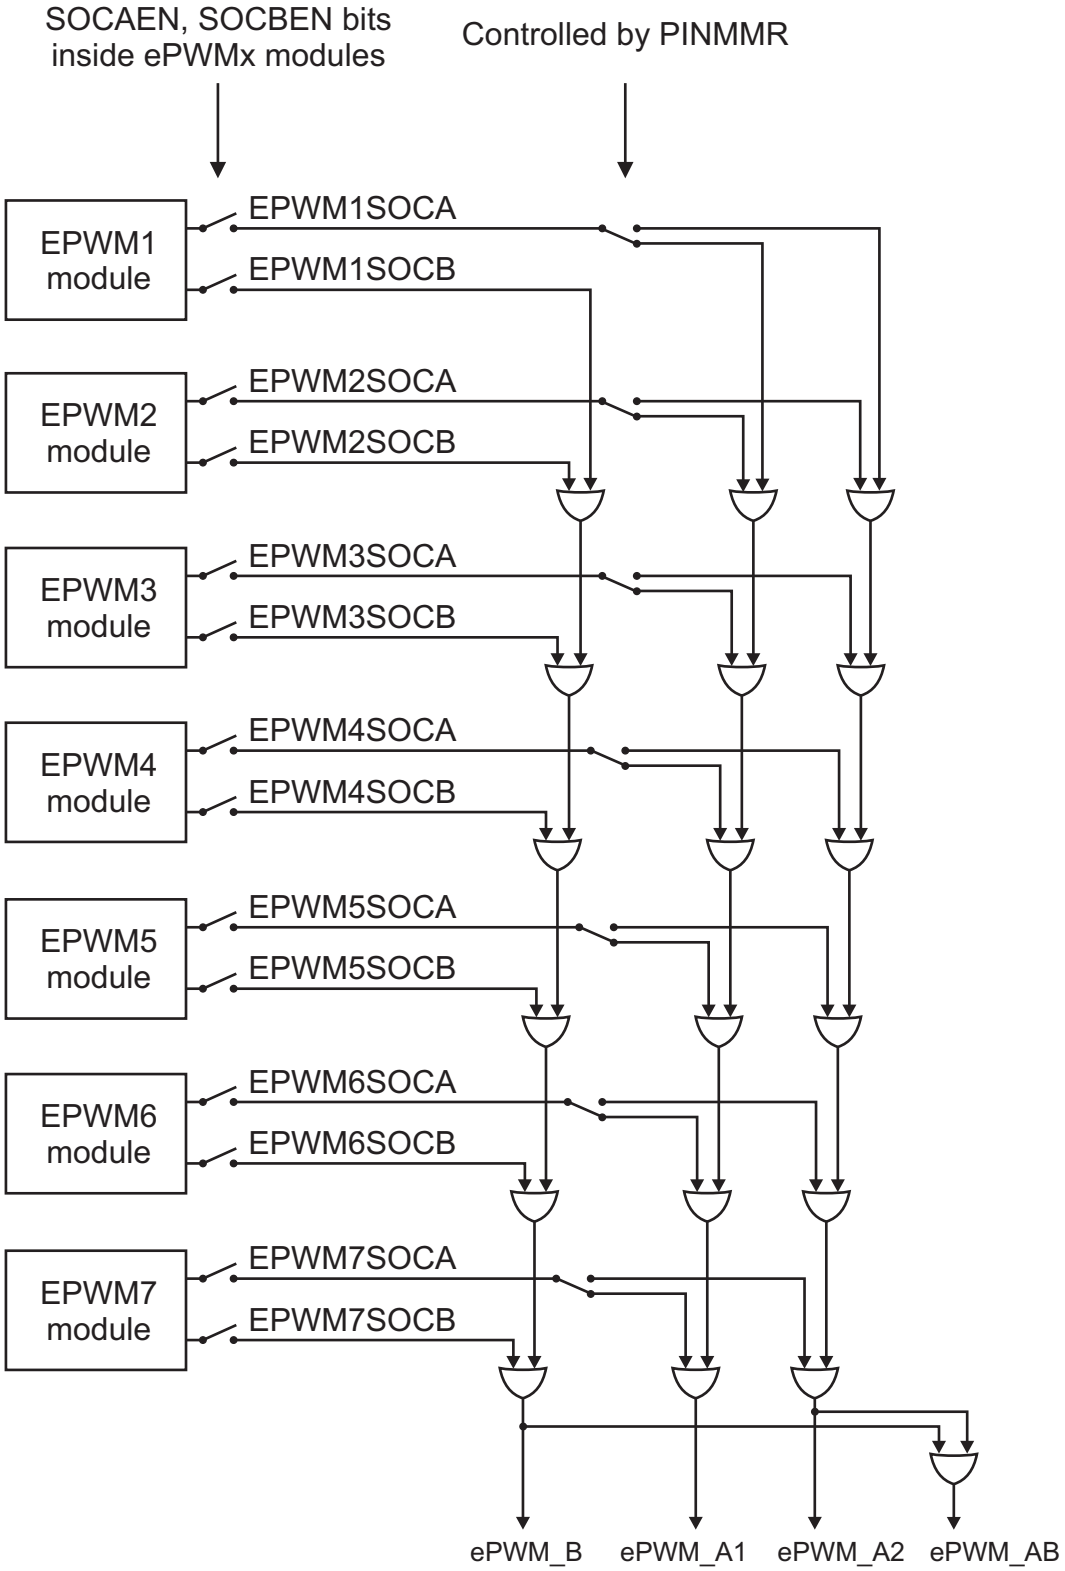
35.2.8 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Every third event
- Provides full visibility of event generation via event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and/or a start of conversion pulse to the ADC when a selected event occurs. Figure 35-38 illustrates where the event-trigger submodule fits within the ePWM system.

Figure 35-38. Event-Trigger Submodule



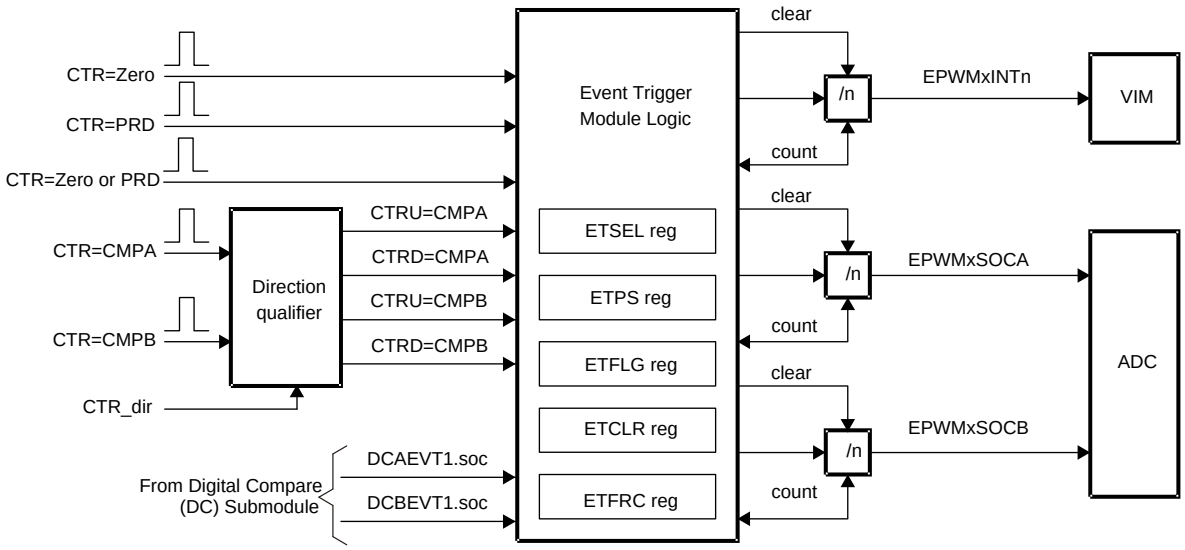
35.2.8.1 Operational Overview of the Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

Each ePWM module has one interrupt request line connected to the VIM and two start of conversion signals connected to the ADC module. As shown in Figure 35-39, the ePWMxSOCA and ePWMxSOCB signals are combined to generate four special signals that can be used to trigger an ADC start of conversion, and hence multiple modules can initiate an ADC start of conversion via the ADC trigger inputs.

Copyright © 2018, Texas Instruments Incorporated

Figure 35-39. Event-Trigger Submodule Inter-Connectivity of ADC Start of Conversion



Copyright © 2018, Texas Instruments Incorporated

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 35-40) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Every third event

Figure 35-40. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs

The key registers used to configure the event-trigger submodule are listed in Table 35-20.

Table 35-20. Event-Trigger Submodule Registers

Register Name	Address Offset	Shadowed	Description
ETSEL	30h	No	Event-trigger Selection Register
ETFLG	34h	No	Event-trigger Flag Register
ETPS	36h	No	Event-trigger Prescale Register
ETFRC	38h	No	Event-trigger Force Register
ETCLR	3Ah	No	Event-trigger Clear Register

- ETSEL—This selects which of the possible events will trigger an interrupt or start an ADC conversion
- ETPS—This programs the event prescaling options mentioned above.
- ETFLG—These are flag bits indicating status of the selected and prescaled events.
- ETCLR—These bits allow you to clear the flag bits in the ETFLG register via software.
- ETFRC—These bits allow software forcing of an event. Useful for debugging or s/w intervention.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in Figure 35-41, Figure 35-42, and Figure 35-43.

Copyright © 2018, Texas Instruments Incorporated

Figure 35-41 shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

Which event can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x0000).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x0000 || TBCTR = TBPRD)
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (ETPS[INTCNT]) register bits. That is, when the specified event occurs the ETPS[INTCNT] bits are incremented until they reach the value specified by ETPS[INTPRD]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the VIM.

When ETPS[INTCNT] reaches ETPS[INTPRD] the following behaviors will occur:

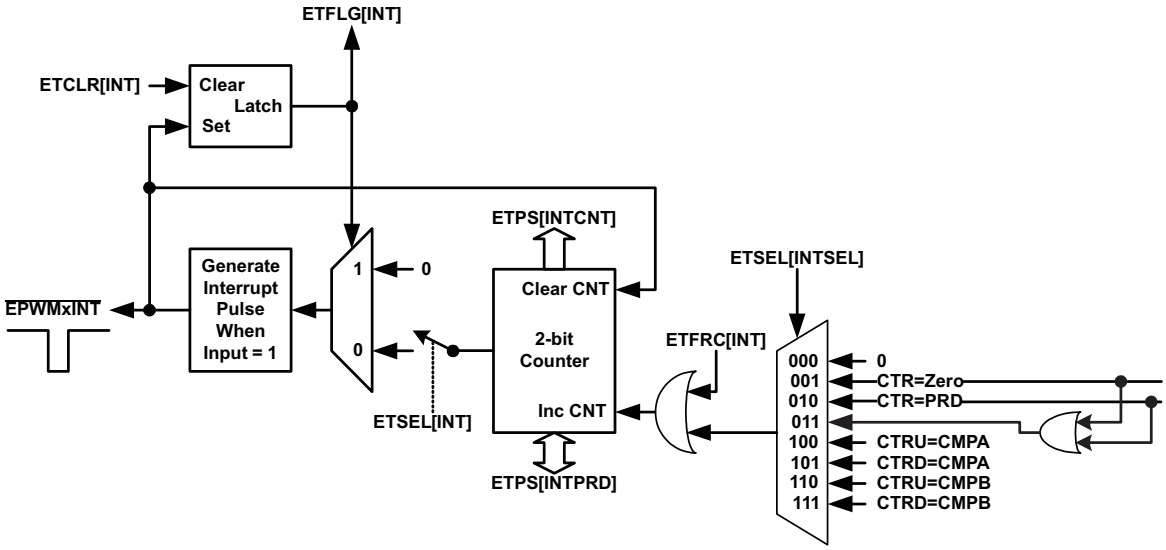
- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored.

The above definition means that you can generate an interrupt on every event, on every second event, or on every third event. An interrupt cannot be generated on every fourth or more events.

Copyright © 2018, Texas Instruments Incorporated

Figure 35-41. Event-Trigger Interrupt Generator



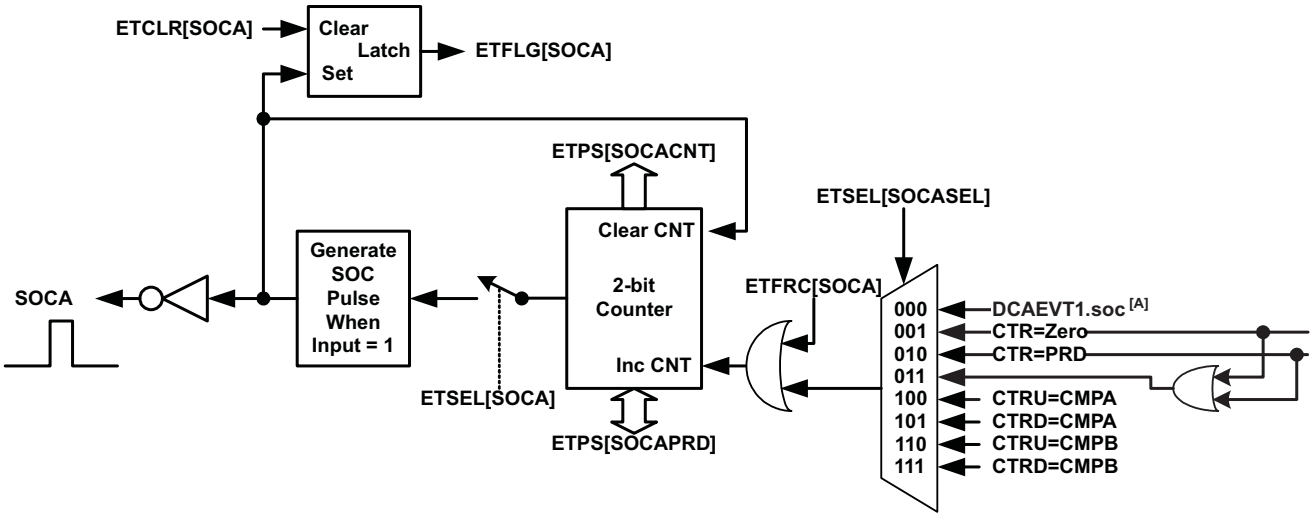


Figure 35-42 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule.

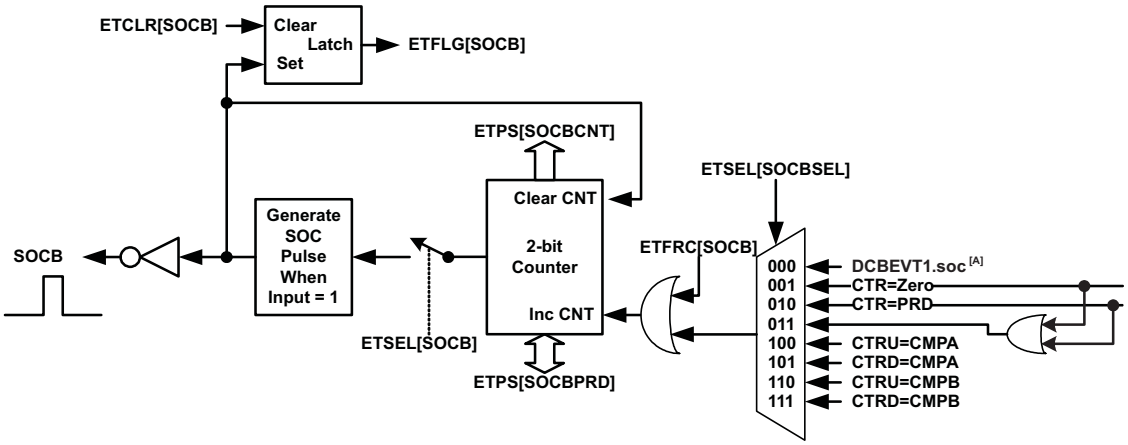
Figure 35-42. Event-Trigger SOCA Pulse Generator

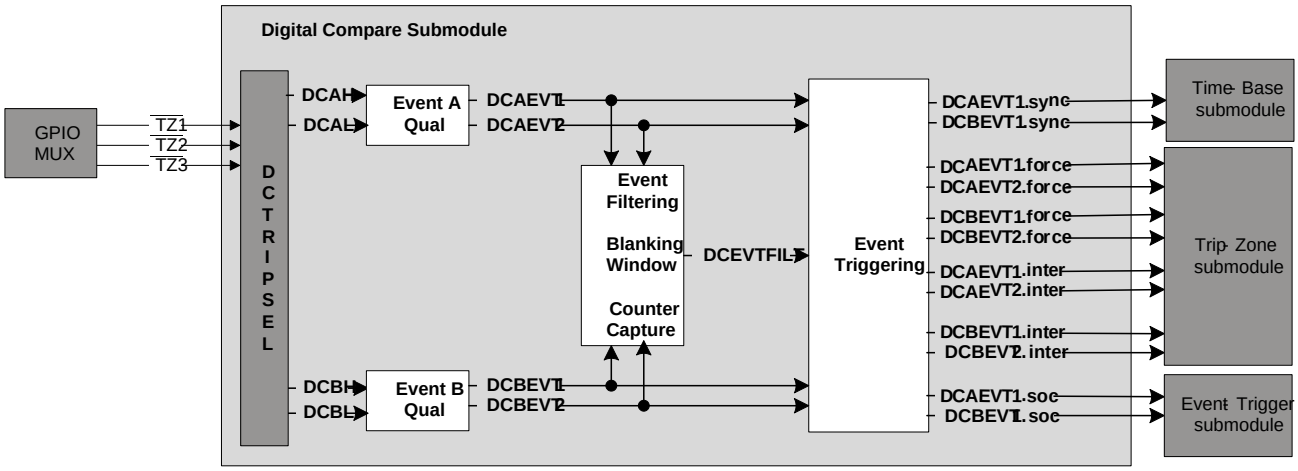


A The DCAEVT1.soc signals are signals generated by the Digital compare (DC) submodule, described in Section 35.2.9

Copyright © 2018, Texas Instruments Incorporated

Figure 35-43 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

Figure 35-43. Event-Trigger SOCB Pulse Generator



A The DCBEVT1.soc signals are signals generated by the Digital compare (DC) submodule, described in Section 35.2.9

35.2.9 Digital Compare (DC) Submodule

Figure 35-44 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The digital compare (DC) submodule compares signals external to the ePWM module to directly generate PWM events/actions which then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

35.2.9.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- $\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$ inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events which can then either be filtered or fed directly to the trip-zone, event-trigger, and time-base submodules to:
  - generate a trip zone interrupt
  - generate an ADC start of conversion
  - force an event
  - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

35.2.9.2 Controlling and Monitoring the Digital Compare Submodule

The digital compare submodule operation is controlled and monitored through the following registers:

Table 35-21. Digital Compare Submodule Registers

Register Name	Address Offset	Shadowed	Description
TZDCSEL[1] [2]	24h	No	Trip Zone Digital Compare Select Register
DCACTL[1]	60h	No	Digital Compare A Control Register
DCTRIPSEL[1]	62h	No	Digital Compare Trip Select Register
DCFCTL[1]	64h	No	Digital Compare Filter Control Register
DCBCTL[1]	66h	No	Digital Compare B Control Register
DCFOFFSET	68h	Writes	Digital Compare Filter Offset Register
DCCAPCTL[1]	6Ah	No	Digital Compare Capture Control Register
DCFWINDOW	6Ch	No	Digital Compare Filter Window Register
DCFOFFSETCNT	6Eh	No	Digital Compare Filter Offset Counter Register
DCCAP	70h	Yes	Digital Compare Counter Capture Register
DCFWINDOWCNT	72h	No	Digital Compare Filter Window Counter Register

(1) These registers are writable only in privileged mode.

(2) The TZDCSEL register is part of the trip-zone submodule but is mentioned again here because of its functional significance to the digital compare submodule.

35.2.9.3 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

35.2.9.3.1 Digital Compare Events

As illustrated in Figure 35-44 earlier in this section, trip zone inputs ($\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$) can be selected via the DCTRIPSEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

NOTE: The $\overline{TZn}$ signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active high or active low inputs. EPWM outputs are asynchronously tripped when either the $\overline{TZn}$, DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of 3*TBCLK sync pulse width is required. If pulse width is < 3*TBCLK sync pulse width, the trip condition may or may not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in section 2.9.3.2. Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:**

  DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (via TZCTL[DCAEVT1 or DCAEVT2] configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (via the TZSEL register), the DCAEVT1/2.force signals can effect the trip action via the TZCTL[TZA] configuration. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

  The priority of conflicting actions on the TZCTL register is as follows (highest priority overrides lower priority):

  Output EPWMxA: TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)

  Output EPWMxB: TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)

- **interrupt signal:**

  DCAEVT1/2.interrupt signals generate trip zone interrupts to the VIM. To enable the interrupt, the user must set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set in order to clear the interrupt.

- **soc signal:**

  The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse via the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse via the ETSEL[SOCBSEL] bit.

- **sync signal:**

  The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCI input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

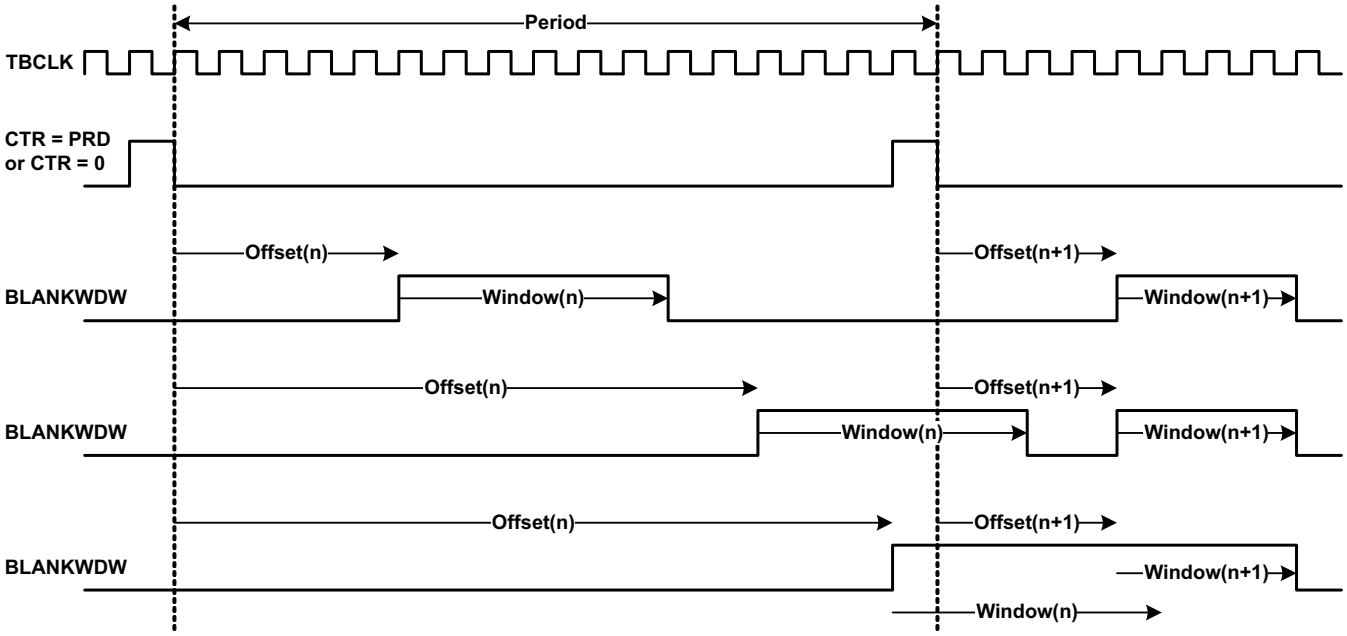
35.2.9.3.2 Event Filtering

The DCAEVT1/2 and DCBEVT1/2 events can be filtered via event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs may be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blanking logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. The event filtering can also capture the TBCTR value of the trip event. Figure 35-49 shows the details of the event filtering logic.

Figure 35-49. Event Filtering



If the blanking logic is enabled, one of the digital compare events – DCAEVT1, DCAEVT2, DCBEVT1, DCBEVT2 – is selected for filtering. The blanking window, which filters out all event occurrences on the signal while it is active, will be aligned to either a CTR = PRD pulse or a CTR = 0 pulse (configured by the DCFCTL[PULSESEL] bits). An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. During the blanking window, all events are ignored. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before.

Figure 35-50 shows several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

Figure 35-50. Blanking Window Timing Diagram

35.2.10 Proper Interrupt Initialization Procedure

When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is as follows:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Set TBCLKSYNC = 0
4. Initialize peripheral registers
5. Set TBCLKSYNC = 1
6. Clear any spurious ePWM flags (including interrupt flags)
7. Enable ePWM interrupts
8. Enable global interrupts

35.3 Application Examples

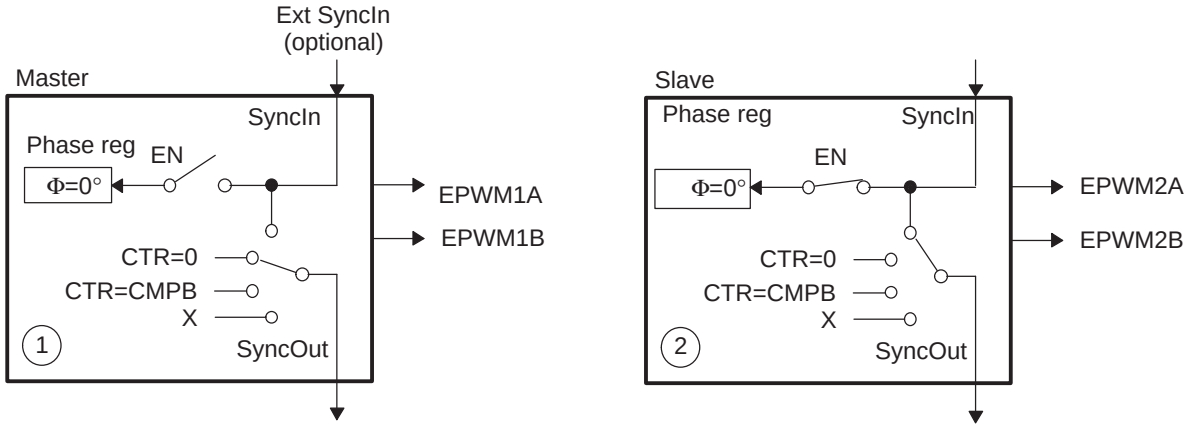
An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

35.3.1 Overview of Multiple Modules

Previously in this user's guide, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in Figure 35-51. This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

Figure 35-51. Simplified ePWM Module

35.3.2 Key Configuration Capabilities



The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it, i.e., via the enable switch. Although various combinations are possible, the two most common—master module and slave module modes—are shown in Figure 35-52.

35.3.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 35-53 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. Figure 35-54 shows the waveforms generated by the setup shown in Figure 35-53; note that only three waveforms are shown, although there are four stages.

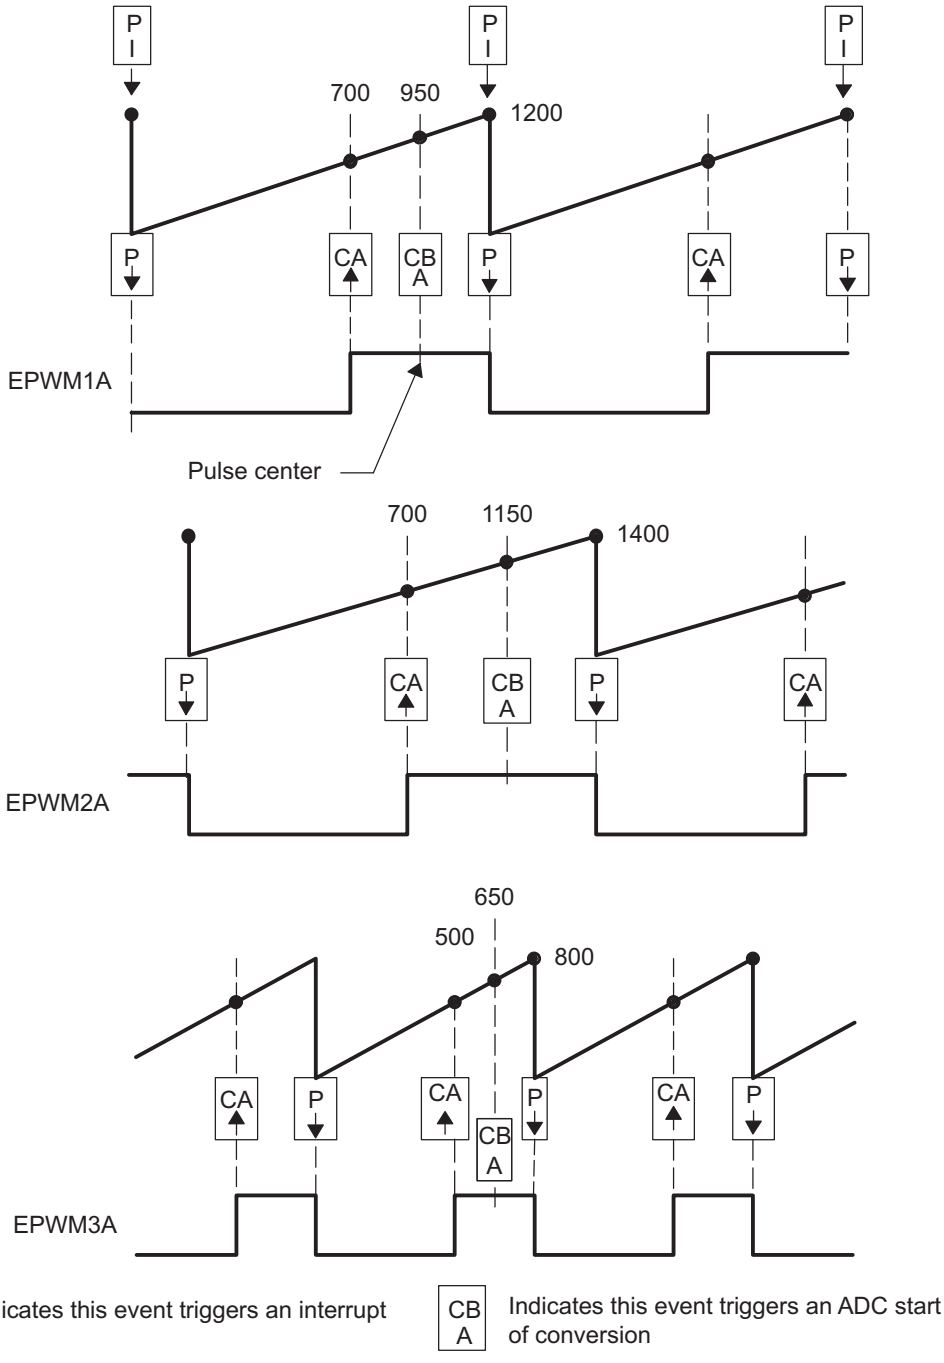

Figure 35-53. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$

NOTE: Θ = X indicates value in phase register is a "don't care"

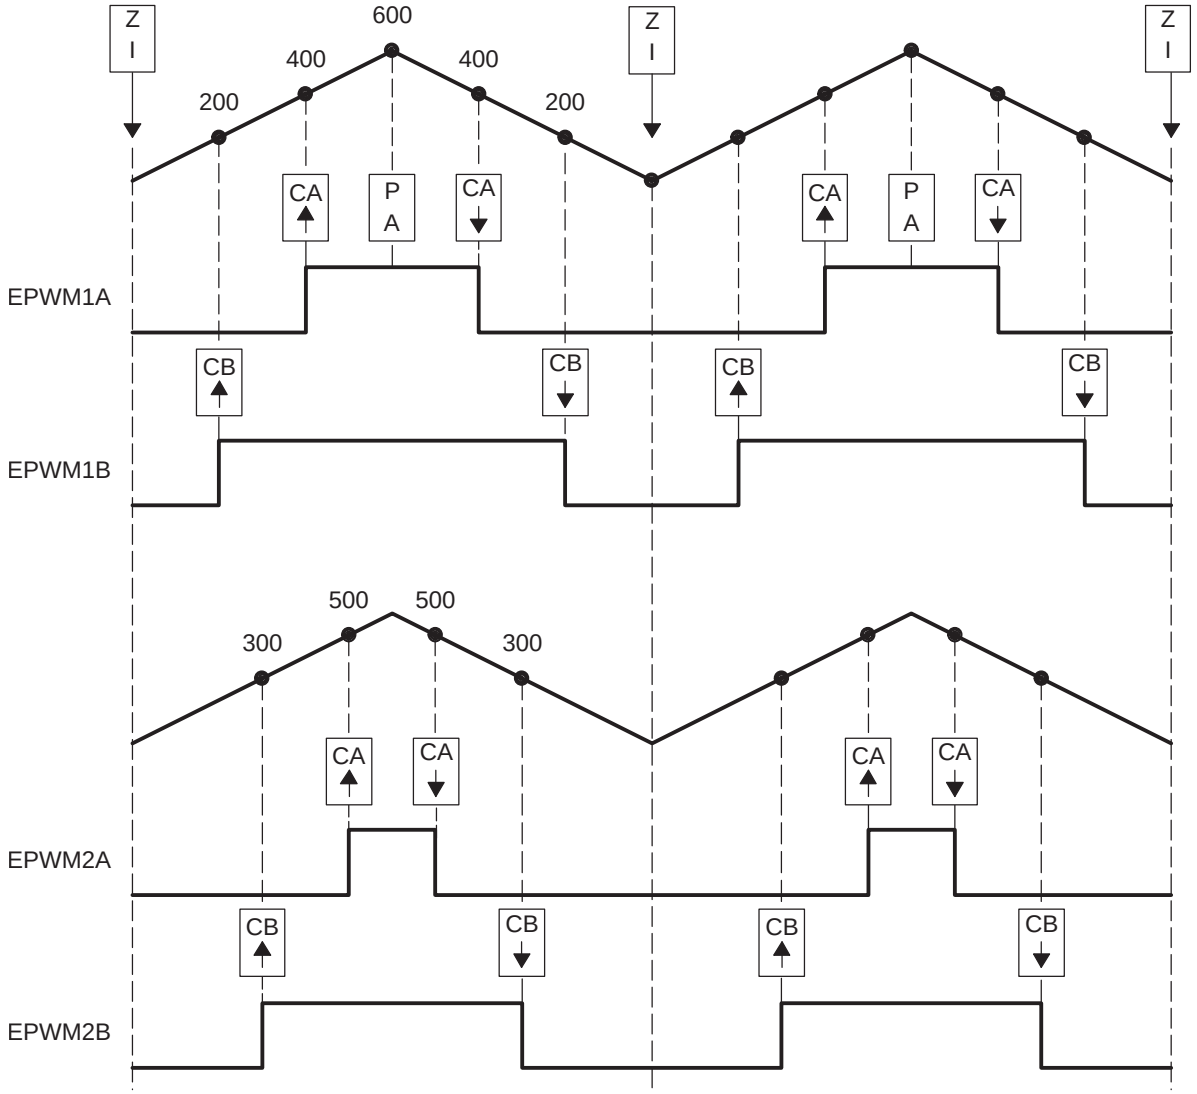
35.3.4 Controlling Multiple Buck Converters With Same Frequencies



If synchronization is a requirement, ePWM module 2 can be configured as a slave and can operate at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. Figure 35-55 shows such a configuration; Figure 35-56 shows the waveforms generated by the configuration.

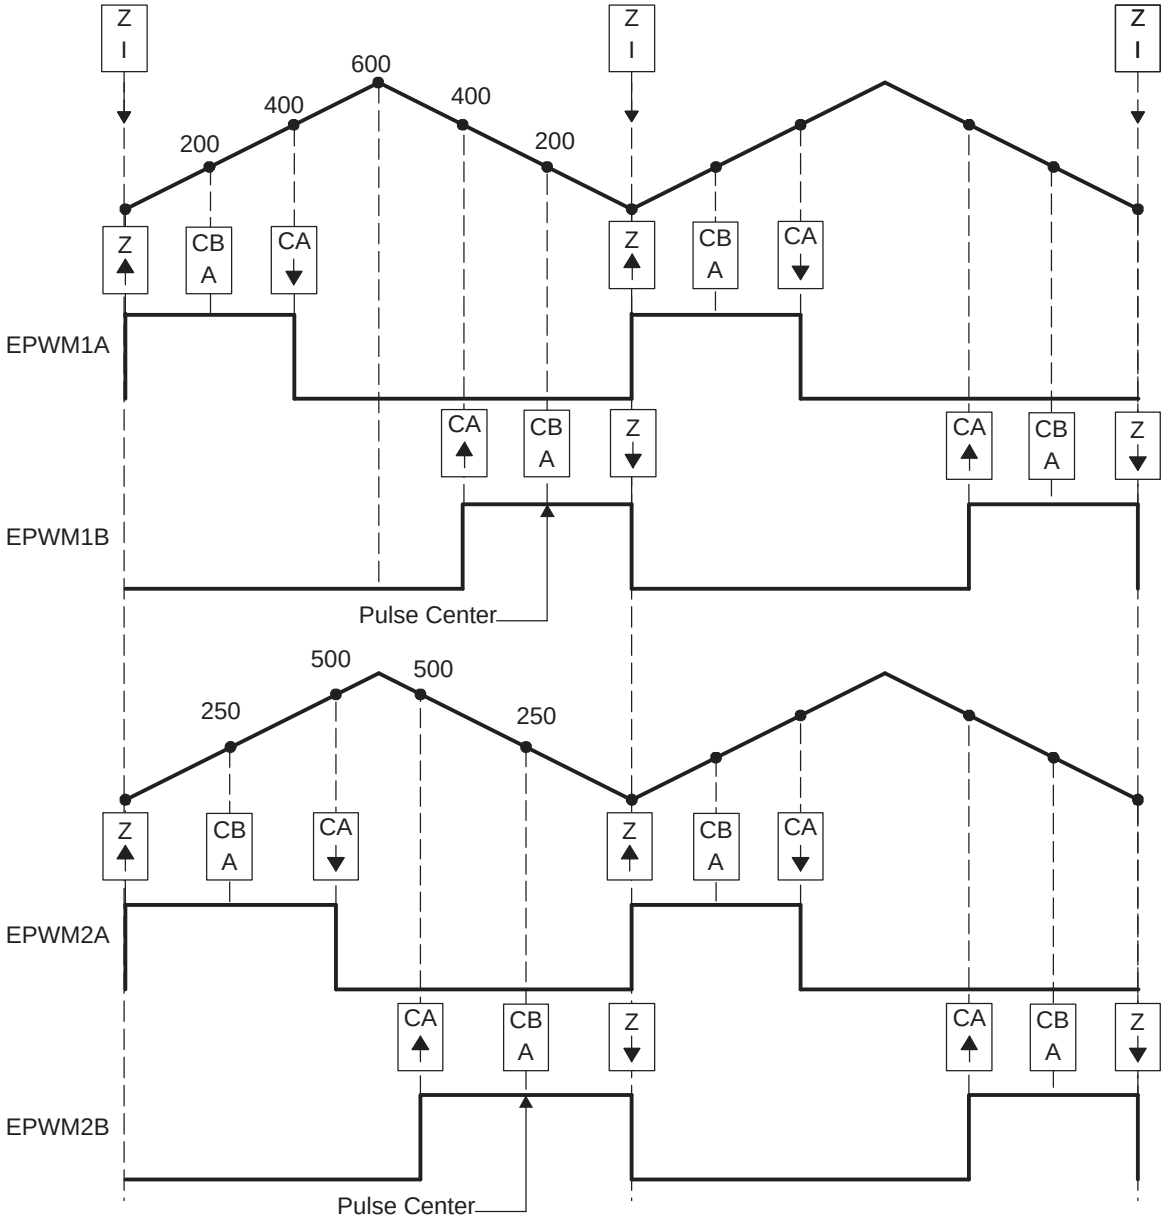
35.3.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 35-57 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 35-58 shows the waveforms generated by the configuration shown in Figure 35-57.



Module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by PWM module 3 and also, most importantly, to remain in synchronization with master module 1.

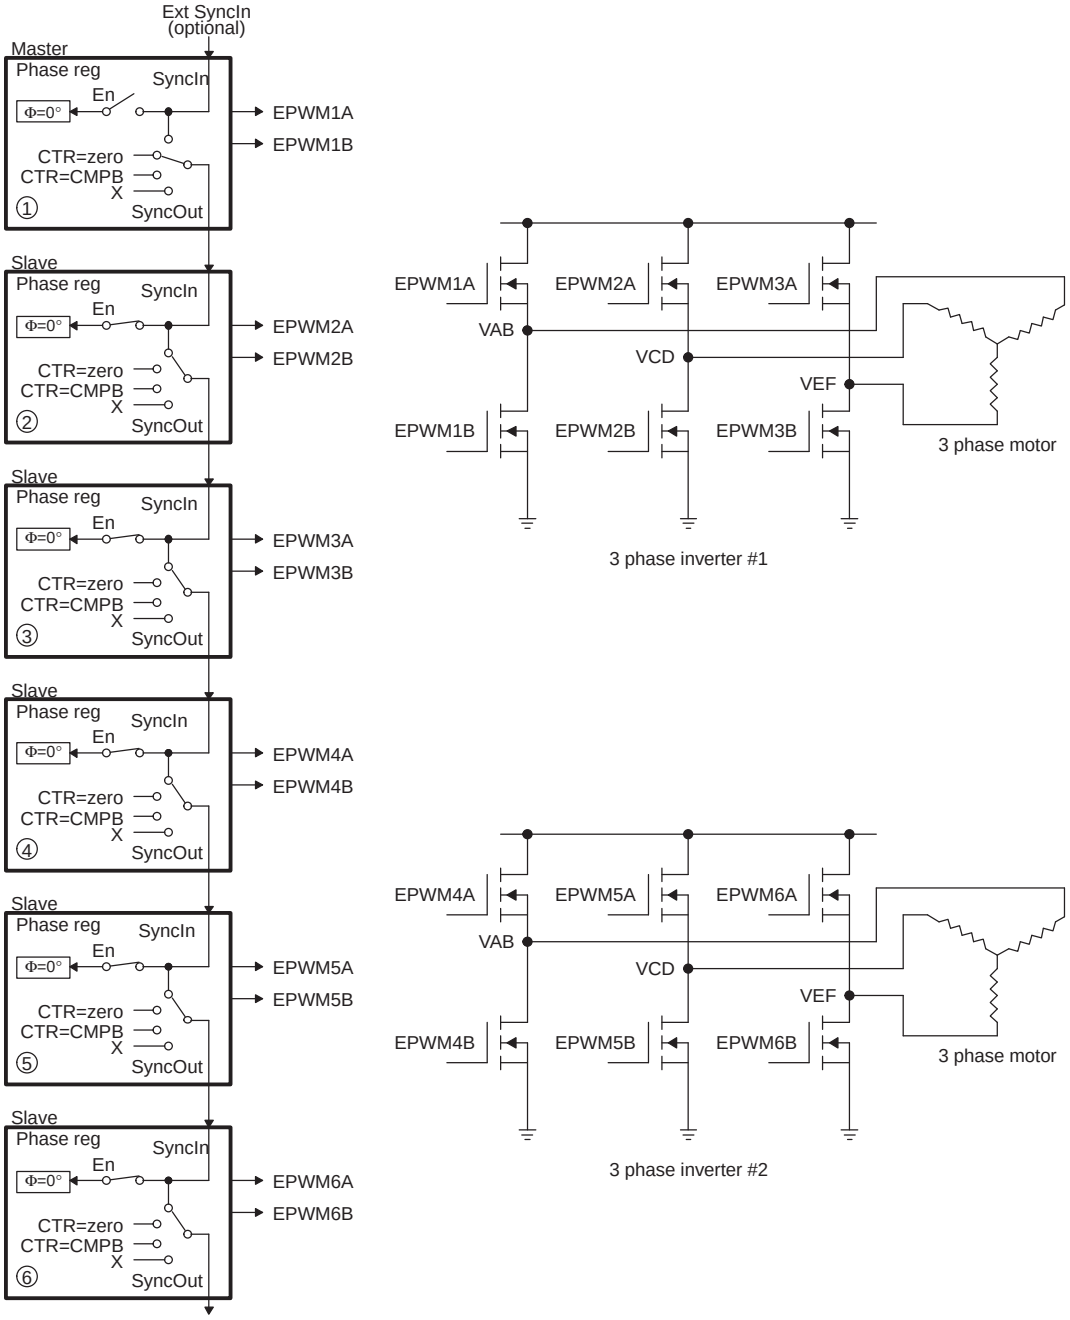
     EPwm2Regs.CMPA.half.CMPA = 500;               // adjust duty for output EPWM2A & EPWM2B
     EPwm2Regs.CMPB = 250;                         // adjust point-in-time for ADCSOC trigger
```



35.3.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. Figure 35-59 shows how six PWM modules can control two independent 3-phase Inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in Figure 35-59), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

35.3.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or its value has been a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of applications that rely on phase relationship between stages for correct operation. As described in the TB module section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, Figure 35-61 shows a master and slave module with a phase relationship of 120°, i.e., the slave leads the master.

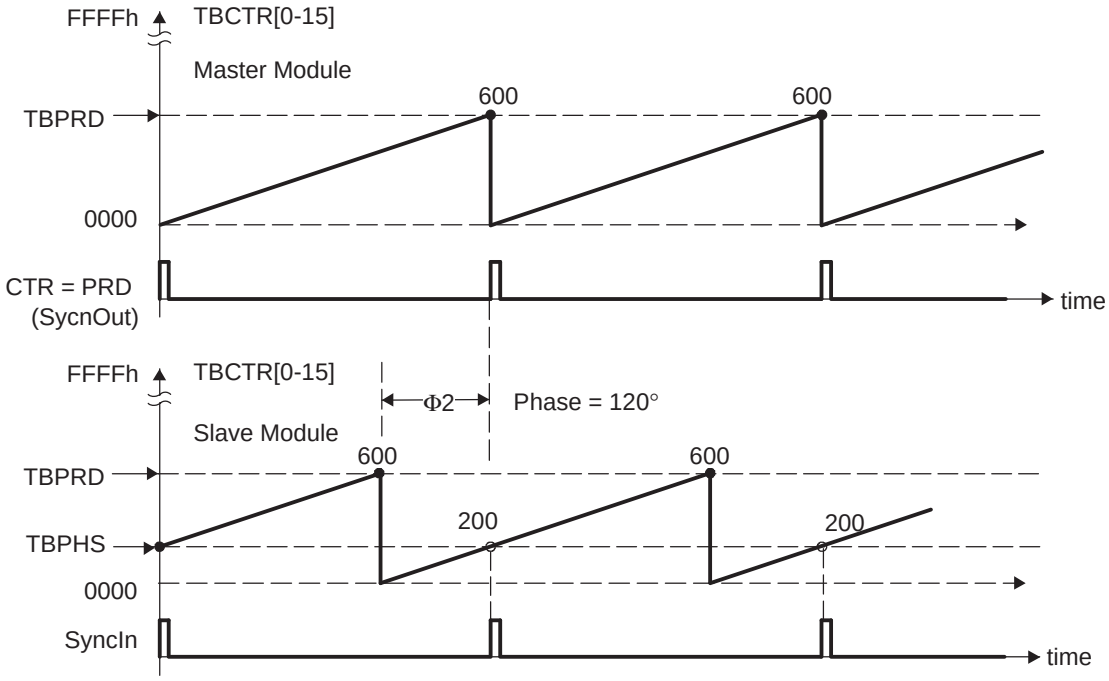

Figure 35-61. Configuring Two PWM Modules for Phase Control

Copyright © 2018, Texas Instruments Incorporated

Figure 35-62 shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 (200/600 × 360° = 120°). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCTR register so the slave time-base is always leading the master's time-base by 120°.

35.4 ePWM Registers

Table 35-22 lists the complete ePWM module control and status register set grouped by submodule. Each register set is duplicated for each instance of the ePWM module. The base address for the control registers is FCF7 8C00h for ePWM1, FCF7 8D00h for ePWM2, FCF7 8E00h for ePWM3, FCF7 8F00h for ePWM4, FCF7 9000h for ePWM5, FCF7 9100h for ePWM6, and FCF7 9200h for ePWM7.

Table 35-23. Time-Base Status Register (TBSTS) Field Descriptions

Bit	Field	Value	Description
15-3	Reserved	0	Reserved
2	CTRMAX		Time-Base Counter Max Latched Status Bit.
		0	Read: Indicates the time-base counter never reached its maximum value. Write: No effect.
		1	Read: Indicates that the time-base counter reached the maximum value 0xFFFF. Write: Clears the latched event.
1	SYNCI		Input Synchronization Latched Status Bit.
		0	Read: Indicates no external synchronization event has occurred. Write: No effect.
		1	Read: Indicates that an external synchronization event has occurred (EPWMxSYNCI). Write: Clears the latched event.
0	CTRDIR		Time-Base Counter Direction Status Bit. At reset, the counter is frozen; therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via TBCTL[CTRMODE].
		0	Time-Base Counter is currently counting down.
		1	Time-Base Counter is currently counting up.

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 35-24. Time-Base Control Register (TBCTL) Field Descriptions

Bit	Field	Value	Description
15-14	FREE, SOFT		Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events:
		0	Stop after the next time-base counter increment or decrement.
		1h	Stop when counter completes a whole cycle: • Up-count mode: stop when the time-base counter = period (TBCTR = TBPRD) • Down-count mode: stop when the time-base counter = 0x0000 (TBCTR = 0x0000) • Up-down-count mode: stop when the time-base counter = 0x0000 (TBCTR = 0x0000)
		2h-3h	Free run
13	PHSDIR		Phase Direction Bit. This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event.. In the up-count and down-count modes this bit is ignored.
		0	Count down after the synchronization event.
		1	Count up after the synchronization event.
12-10	CLKDIV		Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value: TBCLK = VCLK3 / (HSPCLKDIV × CLKDIV)
		0	/1 (default on reset)
		1h	/2
		2h	/4
		3h	/8
		4h	/16
		5h	/32
		6h	/64
		7h	/128
9-7	HSPCLKDIV		High Speed Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value: TBCLK = VCLK3 / (HSPCLKDIV × CLKDIV)
		0	/1
		1h	/2 (default on reset)
		2h	/4
		3h	/6
		4h	/8
		5h	/10
		6h	/12
		7h	/14

Copyright © 2018, Texas Instruments Incorporated

Table 35-24. Time-Base Control Register (TBCTL) Field Descriptions (continued)

Bit	Field	Value	Description
6	SWFSYNC		Software Forced Synchronization Pulse.
		0	Writing a 0 has no effect and reads always return a 0.
		1	Writing a 1 forces a one-time synchronization pulse to be generated.
			This event is ORed with the EPWMxSYNCI input of the ePWM module.
			SWFSYNC is valid (operates) only when EPWMxSYNCI is selected by SYNCOSEL = 00.
5-4	SYNCOSEL		Synchronization Output Select. These bits select the source of the EPWMxSYNCO signal.
		0	EPWMxSYNC
		1h	CTR = zero: Time-base counter equal to zero (TBCTR = 0x0000)
		2h	CTR = CMPB : Time-base counter equal to counter-compare B (TBCTR = CMPB)
		3h	Disable EPWMxSYNCO signal
3	PRDLD		Active Period Register Load From Shadow Register Select.
		0	The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to zero.
			A write or read to the TBPRD register accesses the shadow register.
		1	Load the TBPRD register immediately without using a shadow register.
			A write or read to the TBPRD register directly accesses the active register.
2	PHSEN		Counter Register Load From Phase Register Enable.
		0	Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS).
		1	Load the time-base counter with the phase register when an EPWMxSYNCI input signal occurs or when a software synchronization is forced by the SWFSYNC bit, or when a digital compare sync event occurs.
1-0	CTRMODE		Counter Mode.
			The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change.
			These bits set the time-base counter mode of operation as follows:
		0	Up-count mode
		1h	Down-count mode
		2h	Up-down-count mode
		3h	Stop-freeze counter operation (default on reset)

35.4.1.3 Time-Base Phase Register (TBPHS)

Figure 35-65. Time-Base Phase Register (TBPHS) [offset = 04h]

15	0
TBPHS	
R/W-0	

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 35-25. Time-Base Phase Register (TBPHS) Field Descriptions

Bits	Name	Description
15-0	TBPHS	These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal. • If TBCTL[PHSEN] = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase. • If TBCTL[PHSEN] = 1, then the time-base counter (TBCTR) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCI) or by a software forced synchronization.

35.4.1.4 Time-Base Period Register (TBPRD)

Figure 35-66. Time-Base Period Register (TBPRD) [offset = 08h]

15	0
TBPRD	
R/W-0	

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 35-26. Time-Base Period Register (TBPRD) Field Descriptions

Bits	Name	Description
15-0	TBPRD	These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDLD] bit. By default this register is shadowed. • If TBCTL[PRDLD] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals 0. • If TBCTL[PRDLD] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. • The active and shadow registers share the same memory map address.

35.4.1.5 Time-Base Counter Register (TBCTR)

Figure 35-67. Time-Base Counter Register (TBCTR) [offset = 0Ah]

15	0
TBCTR	
R/W-0	

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 35-27. Time-Base Counter Register (TBCTR) Field Descriptions

Bits	Name	Description
15-0	TBCTR	Reading these bits gives the current time-base counter value. Writing to these bits sets the current time-base counter value. The update happens as soon as the write occurs; the write is NOT synchronized to the time-base clock (TBCLK) and the register is not shadowed.

R-0	R/W-0	R-0	R/W-0	R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 35-28. Counter-Compare Control Register (CMPCTL) Field Descriptions

Bits	Name	Value	Description
15-10	Reserved	0	Reserved
9	SHDWBFULL		Counter-compare B (CMPB) Shadow Register Full Status Flag.
			This bit self clears once a load-strobe occurs.
		0	CMPB shadow FIFO not full yet.
		1	Indicates the CMPB shadow FIFO is full; a CPU write will overwrite current shadow value.
8	SHDWAFULL		Counter-compare A (CMPA) Shadow Register Full Status Flag.
			The flag bit is set when a 32-bit write to CMPA:CMPAHR register or a 16-bit write to CMPA register is made. A 16-bit write to CMPAHR register will not affect the flag.
			This bit self clears once a load-strobe occurs.
		0	CMPA shadow FIFO not full yet.
		1	Indicates the CMPA shadow FIFO is full, a CPU write will overwrite the current shadow value.
7	Reserved	0	Reserved
6	SHDWBMODE		Counter-compare B (CMPB) Register Operating Mode.
		0	Shadow mode. Operates as a double buffer. All writes via the CPU access the shadow register.
		1	Immediate mode. Only the active compare B register is used. All writes and reads directly access the active register for immediate compare action.
5	Reserved	0	Reserved
4	SHDWAMODE		Counter-compare A (CMPA) Register Operating Mode.
		0	Shadow mode. Operates as a double buffer. All writes via the CPU access the shadow register.
		1	Immediate mode. Only the active compare register is used. All writes and reads directly access the active register for immediate compare action.
3-2	LOADBMODE		Active Counter-Compare B (CMPB) Load From Shadow Select Mode. This bit has no effect in immediate mode (CMPCTL[SHDWBMODE] = 1).
		0	Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
		1h	Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD)
		2h	Load on either CTR = Zero or CTR = PRD
		3h	Freeze (no loads possible)
1-0	LOADAMODE		Active Counter-Compare A (CMPA) Load From Shadow Select Mode. This bit has no effect in immediate mode (CMPCTL[SHDWAMODE] = 1).
		0	Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
		1h	Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD)
		2h	Load on either CTR = Zero or CTR = PRD
		3h	Freeze (no loads possible)

35.4.2.2 Counter-Compare A Register (CMPA)

Figure 35-69. Counter-Compare A Register (CMPA) [offset = 10h]

15	0
CMPA	
R/W-0	

LEGEND: R/W = Read/Write; -n = value after reset

Table 35-29. Counter-Compare A Register (CMPA) Field Descriptions

Bits	Name	Description
15-0	CMPA	The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include: • Do nothing; the event is ignored. • Clear: Pull the EPWMxA and/or EPWMxB signal low. • Set: Pull the EPWMxA and/or EPWMxB signal high. • Toggle the EPWMxA and/or EPWMxB signal. Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed. • If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register. • Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full. • If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. • In either mode, the active and shadow registers share the same memory map address.

Copyright © 2018, Texas Instruments Incorporated

35.4.2.3 Counter-Compare B Register (CMPB)

Figure 35-70. Counter-Compare B Register (CMPB) [offset = 16h]

15	0
CMPB	
R/W-0	

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 35-30. Counter-Compare B Register (CMPB) Field Descriptions

Bits	Name	Description
15-0	CMPB	The value in the active CMPB register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare B" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include: • Do nothing. event is ignored. • Clear: Pull the EPWMxA and/or EPWMxB signal low. • Set: Pull the EPWMxA and/or EPWMxB signal high. • Toggle the EPWMxA and/or EPWMxB signal. Shadowing of this register is enabled and disabled by the CMPCTL[SHDWBMODE] bit. By default this register is shadowed. • If CMPCTL[SHDWBMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADBMODE] bit field determines which event will load the active register from the shadow register: • Before a write, the CMPCTL[SHDWBFULL] bit can be read to determine if the shadow register is currently full. • If CMPCTL[SHDWBMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. • In either mode, the active and shadow registers share the same memory map address.

3-2	PRD		Action when the counter equals the period. Note: By definition, in count up-down mode when the counter equals period the direction is defined as 0 or counting down.
		0	Do nothing (action is disabled).
		1h	Clear: force EPWMxB output low.
		2h	Set: force EPWMxB output high.
		3h	Toggle EPWMxB output: low output signal will be forced high, and a high signal will be forced low.
1-0	ZRO		Action when counter equals zero. Note: By definition, in count up-down mode when the counter equals 0 the direction is defined as 1 or counting up.
		0	Do nothing (action is disabled).
		1h	Clear: force EPWMxB output low.
		2h	Set: force EPWMxB output high.
		3h	Toggle EPWMxB output: low output signal will be forced high, and a high signal will be forced low.

35.4.4 Dead-Band Submodule Registers

35.4.4.1 Dead-Band Generator Control Register (DBCTL)

Figure 35-75. Dead-Band Generator Control Register (DBCTL) [offset = 1Ch]

15	14	8
HALFCYCLE	Reserved	
R/W-0	R-0	

7	6	5	4	3	2	1	0
Reserved		IN_MODE		POLSEL		OUT_MODE	
R-0		R/W-0		R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 35-35. Dead-Band Generator Control Register (DBCTL) Field Descriptions

Bits	Name	Value	Description
15	HALFCYCLE		Half Cycle Clocking Enable Bit.
		0	Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate.
		1	Half cycle clocking enabled. The dead-band counters are clocked at TBCLK × 2.
14-6	Reserved	0	Reserved
5-4	IN_MODE		Dead Band Input Mode Control. Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown in Figure 35-28. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays.
		0	EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay.
		1h	EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal.
		2h	EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal.
		3h	EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.
3-2	POLSEL		Polarity Select Control. Bit 3 controls the S3 switch and bit 2 controls the S2 switch shown in Figure 35-28. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0,0. Other enhanced modes are also possible, but not regarded as typical usage modes.
		0	Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default).
		1h	Active low complementary (ALC) mode. EPWMxA is inverted.
		2h	Active high complementary (AHC). EPWMxB is inverted.
		3h	Active low (AL) mode. Both EPWMxA and EPWMxB are inverted.

Copyright © 2018, Texas Instruments Incorporated

Table 35-35. Dead-Band Generator Control Register (DBCTL) Field Descriptions (continued)

Bits	Name	Value	Description
1-0	OUT_MODE		Dead-band Output Mode Control. Bit 1 controls the S1 switch and bit 0 controls the S0 switch shown in Figure 35-28. This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay.
		0	Dead-band generation is bypassed for both output signals. In this mode, both the EPWMxA and EPWMxB output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect.
		1h	Disable rising-edge delay. The EPWMxA signal from the action-qualifier is passed straight through to the EPWMxA input of the PWM-chopper submodule. The falling-edge delayed signal is seen on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].
		2h	The rising-edge delayed signal is seen on output EPWMxA. The input signal for the delay is determined by DBCTL[IN_MODE]. Disable falling-edge delay. The EPWMxB signal from the action-qualifier is passed straight through to the EPWMxB input of the PWM-chopper submodule.
		3h	Dead-band is fully enabled for both rising-edge delay on output EPWMxA and falling-edge delay on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].

Table 35-39. Trip-Zone Submodule Select Register (TZSEL) Field Descriptions

Bits	Name	Value	Description
One-Shot (OSHT) Trip-zone enable/disable. When any of the enabled pins go low, a one-shot trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register is taken on the EPWMxA and EPWMxB outputs. The one-shot trip condition remains latched until the user clears the condition via the TZCLR register.			
15	DCBEVT1		Digital Compare Output B Event 1 Select.
		0	Disable DCBEVT1 as one-shot-trip source for this ePWM module.
		1	Enable DCBEVT1 as one-shot-trip source for this ePWM module.
14	DCAEVT1		Digital Compare Output A Event 1 Select.
		0	Disable DCAEVT1 as one-shot-trip source for this ePWM module.
		1	Enable DCAEVT1 as one-shot-trip source for this ePWM module.
13	OSHT6		Trip-zone 6 ($\overline{TZ6}$) Select.
		0	Disable $\overline{TZ6}$ as a one-shot trip source for this ePWM module.
		1	Enable $\overline{TZ6}$ as a one-shot trip source for this ePWM module.
12	OSHT5		Trip-zone 5 ($\overline{TZ5}$) Select.
		0	Disable $\overline{TZ5}$ as a one-shot trip source for this ePWM module.
		1	Enable $\overline{TZ5}$ as a one-shot trip source for this ePWM module.
11	OSHT4		Trip-zone 4 ($\overline{TZ4}$) Select.
		0	Disable $\overline{TZ4}$ as a one-shot trip source for this ePWM module.
		1	Enable $\overline{TZ4}$ as a one-shot trip source for this ePWM module.
10	OSHT3		Trip-zone 3 ($\overline{TZ3}$) Select.
		0	Disable $\overline{TZ3}$ as a one-shot trip source for this ePWM module.
		1	Enable $\overline{TZ3}$ as a one-shot trip source for this ePWM module.
9	OSHT2		Trip-zone 2 ($\overline{TZ2}$) Select.
		0	Disable $\overline{TZ2}$ as a one-shot trip source for this ePWM module.
		1	Enable $\overline{TZ2}$ as a one-shot trip source for this ePWM module.
8	OSHT1		Trip-zone 1 ($\overline{TZ1}$) Select.
		0	Disable $\overline{TZ1}$ as a one-shot trip source for this ePWM module.
		1	Enable $\overline{TZ1}$ as a one-shot trip source for this ePWM module.
Cycle-by-Cycle (CBC) Trip-zone enable/disable. When any of the enabled pins go low, a cycle-by-cycle trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register is taken on the EPWMxA and EPWMxB outputs. A cycle-by-cycle trip condition is automatically cleared when the time-base counter reaches zero.			
7	DCBEVT2		Digital Compare Output B Event 2 Select.
		0	Disable DCBEVT2 as a CBC trip source for this ePWM module.
		1	Enable DCBEVT2 as a CBC trip source for this ePWM module.
6	DCAEVT2		Digital Compare Output A Event 2 Select.
		0	Disable DCAEVT2 as a CBC trip source for this ePWM module.
		1	Enable DCAEVT2 as a CBC trip source for this ePWM module.

		0	No trip event has occurred on DCAEVT1.
		1	A trip event has occurred for the event defined for DCAEVT1.
2	OST		Latched Status Flag for A One-Shot Trip Event.
		0	No one-shot trip event has occurred.
		1	A trip event has occurred on a pin selected as a one-shot trip source.
			This bit is cleared by writing the appropriate value to the TZCLR register.
1	CBC		Latched Status Flag for Cycle-By-Cycle Trip Event.
		0	No cycle-by-cycle trip event has occurred.
		1	A trip event has occurred on a signal selected as a cycle-by-cycle trip source. The TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x0000) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x0000 no matter where in the cycle the CBC flag is cleared.
			This bit is cleared by writing the appropriate value to the TZCLR register.
0	INT		Latched Trip Interrupt Status Flag.
		0	No interrupt has been generated.
		1	An EPWMx_TZINT VIM interrupt was generated because of a trip condition.
			No further EPWMx_TZINT VIM interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts.
			This bit is cleared by writing the appropriate value to the TZCLR register.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 35-45. Event-Trigger Selection Register (ETSEL) Field Descriptions

Bits	Name	Value	Description
15	SOCBEN		Enable the ADC Start of Conversion B (EPWMxSOCB) Pulse.
		0	Disable EPWMxSOCB.
		1	Enable EPWMxSOCB pulse.
14-12	SOCBSEL		EPWMxSOCB Selection Options.
			These bits determine when a EPWMxSOCB pulse will be generated.
		0	Enable DCBEVT1.soc event.
		1h	Enable event time-base counter equal to zero. (TBCTR = 0x0000).
		2h	Enable event time-base counter equal to period (TBCTR = TBPRD).
		3h	Enable event time-base counter equal to zero or period (TBCTR = 0x0000 or TBCTR = TBPRD). This mode is useful in up-down count mode.
		4h	Enable event time-base counter equal to CMPA when the timer is incrementing.
		5h	Enable event time-base counter equal to CMPA when the timer is decrementing.
		6h	Enable event: time-base counter equal to CMPB when the timer is incrementing.
		7h	Enable event: time-base counter equal to CMPB when the timer is decrementing.
11	SOCAEN		Enable the ADC Start of Conversion A (EPWMxSOCA) Pulse.
		0	Disable EPWMxSOCA.
		1	Enable EPWMxSOCA pulse.
10-8	SOCASEL		EPWMxSOCA Selection Options.
			These bits determine when a EPWMxSOCA pulse will be generated.
		0	Enable DCAEVT1.soc event.
		1h	Enable event time-base counter equal to zero. (TBCTR = 0x0000).
		2h	Enable event time-base counter equal to period (TBCTR = TBPRD).
		3h	Enable event time-base counter equal to zero or period (TBCTR = 0x0000 or TBCTR = TBPRD). This mode is useful in up-down count mode.
		4h	Enable event time-base counter equal to CMPA when the timer is incrementing.
		5h	Enable event time-base counter equal to CMPA when the timer is decrementing.
		6h	Enable event: time-base counter equal to CMPB when the timer is incrementing.
		7h	Enable event: time-base counter equal to CMPB when the timer is decrementing.
7-4	Reserved	0	Reserved
3	INTEN		Enable ePWM Interrupt (EPWMx_INT) Generation.
		0	Disable EPWMx_INT generation.
		1	Enable EPWMx_INT generation.

R-0		R-0	R-0	R-0	R-0

LEGEND: R = Read only; -*n* = value after reset

Table 35-46. Event-Trigger Flag Register (ETFLG) Field Descriptions

Bits	Name	Value	Description
15-4	Reserved	0	Reserved
3	SOCB		Latched ePWM ADC Start-of-Conversion B (EPWMxSOCB) Status Flag.
		0	No EPWMxSOCB event occurred.
		1	A start of conversion pulse was generated on EPWMxSOCB. The EPWMxSOCB output will continue to be generated even if the flag bit is set.
2	SOCA		Latched ePWM ADC Start-of-Conversion A (EPWMxSOCA) Status Flag. Unlike the ETFLG[INT] flag, the EPWMxSOCA output will continue to pulse even if the flag bit is set.
		0	No event occurred.
		1	A start of conversion pulse was generated on EPWMxSOCA. The EPWMxSOCA output will continue to be generated even if the flag bit is set.
1	Reserved	0	Reserved
0	INT		Latched ePWM Interrupt (EPWMx_INT) Status Flag.
		0	No event occurred.
		1	An ePWMx interrupt (EWPMx_INT) was generated. No further interrupts will be generated until the flag bit is cleared. Up to one interrupt can be pending while the ETFLG[INT] bit is still set. If an interrupt is pending, it will not be generated until after the ETFLG[INT] bit is cleared. Refer to Figure 35-41.

35.4.6.3 Event-Trigger Prescale Register (ETPS)

Figure 35-87. Event-Trigger Prescale Register (ETPS) [offset = 36h]

15	14	13	12	11	10	9	8
SOCBCNT		SOCBPRD		SOCACNT		SOCAPRD	
R-0		R/W-0		R-0		R/W-0	

7	4	3	2	1	0
Reserved		INTCNT		INTPRD	
R-0		R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 35-47. Event-Trigger Prescale Register (ETPS) Field Descriptions

Bits	Name	Value	Description
15-14	SOCBCNT		ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Counter Register. These bits indicate how many selected ETSEL[SOCBSEL] events have occurred.
		0	No events have occurred.
		1h	1 event has occurred.
		2h	2 events have occurred.
		3h	3 events have occurred.
13-12	SOCBPRD		ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Period Select. These bits determine how many selected ETSEL[SOCBSEL] events need to occur before an EPWMxSOCB pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCBEN] = 1). The SOCB pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCB] = 1). Once the SOCB pulse is generated, the ETPS[SOCBCNT] bits will automatically be cleared.
		0	Disable the SOCB event counter. No EPWMxSOCB pulse will be generated.
		1h	Generate the EPWMxSOCB pulse on the first event: ETPS[SOCBCNT] = 0,1.
		2h	Generate the EPWMxSOCB pulse on the second event: ETPS[SOCBCNT] = 1,0.
		3h	Generate the EPWMxSOCB pulse on the third event: ETPS[SOCBCNT] = 1,1.
11-10	SOCACNT		ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Counter Register. These bits indicate how many selected ETSEL[SOCASEL] events have occurred.
		0	No events have occurred.
		1h	1 event has occurred.
		2h	2 events have occurred.
		3h	3 events have occurred.
9-8	SOCAPRD		ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Period Select. These bits determine how many selected ETSEL[SOCASEL] events need to occur before an EPWMxSOCA pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCAEN] = 1). The SOCA pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCA] = 1). Once the SOCA pulse is generated, the ETPS[SOCACNT] bits will automatically be cleared.
		0	Disable the SOCA event counter. No EPWMxSOCA pulse will be generated.
		1h	Generate the EPWMxSOCA pulse on the first event: ETPS[SOCACNT] = 0,1.
		2h	Generate the EPWMxSOCA pulse on the second event: ETPS[SOCACNT] = 1,0.
		3h	Generate the EPWMxSOCA pulse on the third event: ETPS[SOCACNT] = 1,1.
7-4	Reserved	0	Reserved

Copyright © 2018, Texas Instruments Incorporated

Table 35-47. Event-Trigger Prescale Register (ETPS) Field Descriptions (continued)

Bits	Name	Value	Description
3-2	INTCNT		ePWM Interrupt Event (EPWMx_INT) Counter Register. These bits indicate how many selected ETSEL[INTSEL] events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, ETSEL[INT] = 0 or the interrupt flag is set, ETFLG[INT] = 1, the counter will stop counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
		0	No events have occurred.
		1h	1 event has occurred.
		2h	2 events have occurred.
		3h	3 events have occurred.
1-0	INTPRD		ePWM Interrupt (EPWMx_INT) Period Select. These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared. Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented.
		0	Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored.
		1h	Generate an interrupt on the first event INTCNT = 01 (first event).
		2h	Generate interrupt on ETPS[INTCNT] = 1,0 (second event).
		3h	Generate interrupt on ETPS[INTCNT] = 1,1 (third event).

Figure 35-95. Digital Compare Filter Offset Register (DCFOFFSET) [offset = 68h]

15	0
DCOFFSET	
R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 35-55. Digital Compare Filter Offset Register (DCFOFFSET) Field Descriptions

Bit	Field	Description
15-0	OFFSET	Blanking Window Offset These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted.

Table 35-59. Digital Compare Counter Capture Register (DCCAP) Field Descriptions

Bit	Field	Description
15-0	DCCAP	Digital Compare Time-Base Counter Capture. To enable time-base counter capture, set the DCCAPCLT[CAPE] bit to 1. If enabled, reflects the value of the time-base counter (TBCTR) on the low-to-high edge transition of a filtered (DCEVTFLT) event. Further capture events are ignored until the next period or zero as selected by the DCFCTL[PULSESEL] bit. Shadowing of DCCAP is enabled and disabled by the DCCAPCTL[SHDWMODE] bit. By default this register is shadowed. • If DCCAPCTL[SHDWMODE] = 0, then the shadow is enabled. In this mode, the active register is copied to the shadow register on the TBCTR = TBPRD or TBCTR = zero as defined by the DCFCTL[PULSESEL] bit. CPU reads of this register will return the shadow register value. • If DCCAPCTL[SHDWMODE] = 1, then the shadow register is disabled. In this mode, CPU reads will return the active register value. The active and shadow registers share the same memory-map address.

Data Modification Module (DMM)

This chapter describes the functionality of the Data Modification Module (DMM), which provides the capability to modify data in the entire 4 GB address space of the device from an external peripheral, with minimal interruption of the application.

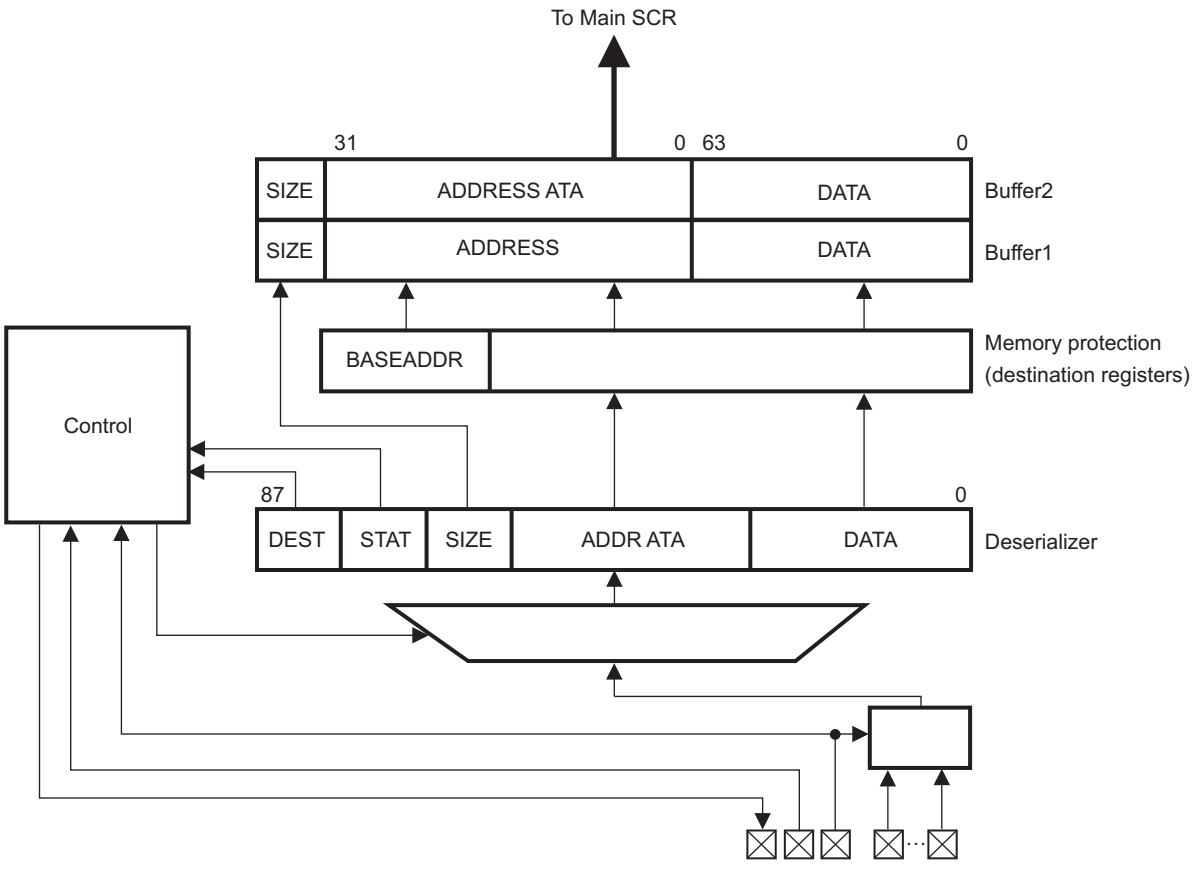
Topic **Page**

36.1 Overview **2109**
36.2 Module Operation **2110**
36.3 Control Registers **2115**

Copyright © 2018, Texas Instruments Incorporated

36.1 Overview

36.1.1 Features



The DMM module has the following features:

- Acts as a bus master, thus enabling direct writes to the 4GB address space without CPU intervention
- Writes to memory locations specified in the received packet (leverages packets defined by trace mode of the RAM trace port (RTP) module
- Writes received data to consecutive addresses, which are specified by the DMM module (leverages packets defined by direct data mode of RTP module)
- Configurable port width (1, 2, 4, 8, 16 pins)
- Up to 100 Mbit/s pin data rate
- Unused pins configurable as GIO pins

36.1.2 Block Diagram

Figure 36-1 shows the block diagram for the DMM.

Figure 36-1. DMM Block Diagram

Copyright © 2018, Texas Instruments Incorporated

36.2 Module Operation

The DMM receives data over the DMM pins from external systems and writes the received data directly to the base address programmed in the module plus offset address given in the packet or into a buffer specified by start address and length. It leverages the protocol defined by the RAM Trace Port (RTP) module to have a common interface definition for external systems. It can also be used to connect an RTP and DMM module together for fast processor intercommunication.

The DMM module provides two modes of operation:

- **Trace Mode:** In this mode, the DMM writes the received data directly to an address that is calculated from the base address programmed into the destination register (Section 36.3.12; Section 36.3.14) plus the offset address contained in the received packet. An interrupt can be generated when data is written the lowest address of a programmed region. This capability enables the sender to raise an interrupt at the receiver while sending specific information.
- **Direct Data Mode:** In this mode, the DMM writes the received data into an address range of the 4GB address space. The buffer start address (Section 36.3.8) and blocksize (Section 36.3.9) is programmable in the DMM module. When the buffer reaches its end address, the buffer pointer wraps around and points to the beginning of the buffer again. The EO_BUFF flag (Section 36.3.5) will be set and if enabled, an interrupt will be generated to indicate a buffer-full condition. Another interrupt, can be configured to indicate different buffer fill levels. This can be accomplished by programming a certain fill level into the DMMINTPT register (Section 36.3.11). The PROG_BUFF flag (Section 36.3.5) indicates that this level has been reached.

Data will be captured by the input buffer and moved to the appropriate bit field in the deseralizer. When the deseralizer is completely full, the data will be moved to the output buffer register. A two-level buffer is implemented to avoid overflow conditions if the internal bus is occupied by other transactions. In addition the $\overline{\text{DMMENA}}$ signal can be used to signal the external hardware that an overflow might occur if more data is sent. The automatic generation of the $\overline{\text{DMMENA}}$ signal can be configured by setting the ENAFUNC bit (Section 36.3.16). While the $\overline{\text{DMMENA}}$ signal is active, the DMM module will not receive any new data.

The DMM is a bus master and forwards the received data to the bus system. The write operation will be minimally intrusive to the program flow, because the CPU/DMA access will only be blocked if the CPU/DMA accesses the same resource as the DMM.

To prevent an external system from overwriting critical data in the memory while configured in Trace Mode, a memory protection mechanism is implemented via a programmable start address and block size of a region. A maximum of four destinations with two regions each are supported.

For proper operation, at least DMMCLK, DMMSYNC and DMMDATA[0] need to be programmed in functional mode (Section 36.3.16). If a large amount of data should be transmitted in a short time, more data pins should be used in functional mode. The module supports 1, 2, 4, 8, or 16-pin configurations.

The module can be configured to handle a free running clock provided on DMMCLK (Section 36.3.1). Clock pulses between two DMMSYNC pulses that exceed the number of valid clock pulses for a packet will be ignored.

36.2.1 Data Format

Below is a description of the packet and frame format.

36.2.1.1 Clocking Scheme

The DMM supports both continuous and noncontinuous clocking. The clock received on DMMCLK in the continuous clocking scheme is a free-running clock. In noncontinuous clocking scheme, the clock will stop after each packet and will start with the reception of a DMMSYNC signal.

36.2.1.2 Trace Mode Packet

Figure 36-2 illustrates the trace mode packet format. One packet consists of 2 bits (DEST) denoting the destination in which the data is stored, 2 status bits (STAT), the 2-bit SIZE of the data, the 18-bit address of where the data should be written to, and a variable data field.

Copyright © 2018, Texas Instruments Incorporated

The DEST bits (Table 36-1) will be used to determine which destination register applies to the transmitted data and the received address determines if the packet falls into a valid region of the destination area. If the address is valid, the base address, programmed in one of the destination registers (Section 36.3.12; Section 36.3.14) of this particular region will be applied to create the complete 32-bit address for the destination. The DMM module only takes action on a "11" setting of the STAT bits (Table 36-2). This signals that an overflow in the transmitting hardware module has occurred. If this is the case the SRC_OVF flag (Section 36.3.5) will be set and the received data will be written to the address specified in the packet. The size information of the data transmitted in the packet is denoted in the SIZE bits (Table 36-3) of the packet. Depending on the SIZE information, the module expects to receive only this amount of data.

Figure 36-2. Trace Mode Packet Format

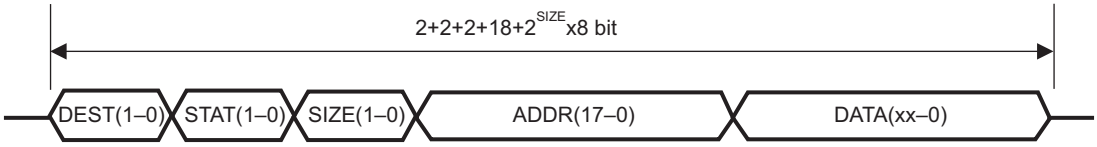


Table 36-1 through Table 36-3 illustrate the encoding of packet format in trace mode.

Table 36-1. Encoding of Destination Bits in Trace Mode Packet Format

DEST[1:0]	Destination
00	Dest 0
01	Dest 1
10	Dest 2
11	Dest 3

Table 36-2. Encoding of Status Bits in Trace Mode Packet Format

STAT[1:0]	Status
00	don't care
01	don't care
10	don't care
11	overflow

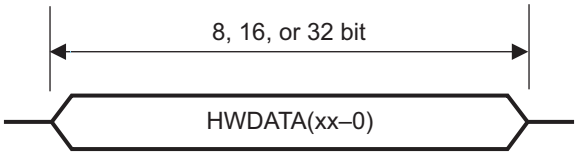

Table 36-3. Encoding of Write Size in Packet Format

SIZE[1:0]	Write Size
00	8 bit
01	16 bit
10	32 bit
11	64 bit

36.2.1.3 Direct Data Mode Packet

Figure 36-3 illustrates the direct data mode packet format.

Figure 36-3. Direct Data Mode Packet Format

Copyright © 2018, Texas Instruments Incorporated

The packet consists only of data bits and no header information. It can be 8-, 16- or 32-bit wide. A variable packet width is not supported because the DMM module will check the number of incoming bits (DMMCLK cycles) for error detection. The DMM will write the received data to the destination once the programmed number of bits has been received.

If the programmed word width does not correspond to the received data, the following actions will be taken:

- If the received data is greater than the programmed width, only the configured number of bits are transferred into the RAM buffer, the additional bits are discarded.
- If the received number of bits is smaller than the programmed width, no data will be written to the buffer, because a new DMMSYNC signal has been received before the expected number of bits.

36.2.2 Data Port

The packet will be received in several subpackets, depending on the width of the external data bus (DMMDATA[y:0]) and the amount of data to be transmitted. Table 36-4 illustrates the number of clock cycles required for a complete packet.

Table 36-4. Number of Clock Cycles per Packet

Port Width/ Pins	Write Size in Bits			
	8	16	32	64
1	32	40	56	88
2	16	20	28	44
4	8	10	14	22
8	4	5	7	11
16	2	3	4	6

The user can program the port width in the DMMPC0 register (Section 36.3.16). This feature allows pins that are not used for DMM functionality to be used as GIO pins. Only the pins shown in Table 36-5 can be used for a desired port width.

Table 36-5. Pins Used for Data Communication

Port Width	Pins Used
1	DMMDATA[0]
2	DMMDATA[1:0]
4	DMMDATA[3:0]
8	DMMDATA[7:0]
16	DMMDATA[15:0]

NOTE: If pins other than the ones specified in Table 36-5 are programmed as functional pins for a desired port width, the received data will be corrupted and will not be transferred to the deserializer.

NOTE: If DMMCLK or DMMSYNC are programmed as nonfunctional pins, functional operation will not occur.

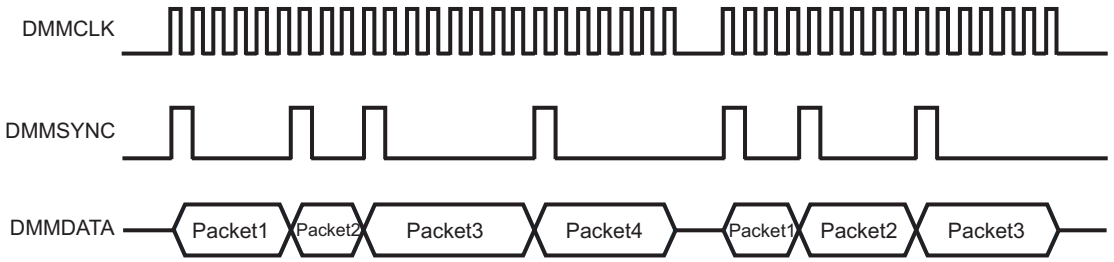
36.2.2.1 Signal Description

DMMSYNC	This signal has to be provided by external hardware. It signals the start of a new packet. It has to be active (high) for one full DMMCLK cycle, starting with the rising edge of DMMCLK. If the DMMSYNC pulse is longer than a single DMMCLK cycle and two falling edges of DMMCLK see a high pulse on DMMSYNC, the module will treat the second DMMSYNC pulse as the start of a packet and will flag a PACKET_ERR_INT (Section 36.3.5).
DMMCLK	The clock is externally generated and can be suspended between two packets. For this feature, CONTCLK must be set to 0 (Section 36.3.1). If the clock is not stopped between two packets, CONTCLK must be set to 1. Data will be latched on the falling edge of the DMMCLK signal.
$\overline{\text{DMMENA}}$	This signal is pulled high if no new data should be received via the data pins, because of a potential overflow situation.
DMMDATA[15:0]	These pins receive the packet information transmitted by the external hardware. Data is latched on the falling edge of DMMCLK.

Figure 36-4 shows an example of multiple packets received during trace mode, in noncontinuous clock configuration.

Figure 36-4. Packet Sync Signal Example



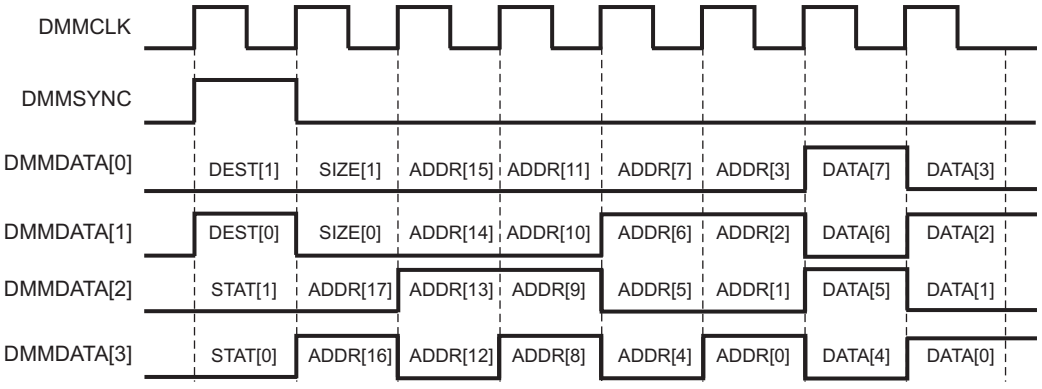


Figure 36-5 shows an example of a 4-bit data port with 8-bit receive data (A5h) to be written into DEST1 (address 0001 2345h) on a trace mode packet.

Figure 36-5. Example Single Packet Transmission

36.2.3 Error Handling

The module will generate two different kind of errors. Once an error condition is recognized, an interrupt will be generated if enabled.

Copyright © 2018, Texas Instruments Incorporated

36.2.3.1 Overflow Error

This error is signaled when the module has received new data before the previous data was written to the destination address. If the internal buffers are full, the DMMENA signal will go high. If the sending module does not evaluate the DMMENA signal and keeps on sending new frames, the data that was previously received might be overwritten, thus resulting in setting the BUFF_OVF flag (Section 36.3.5).

36.2.3.2 Packet Error

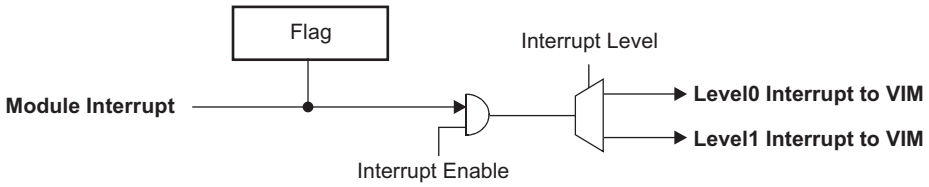
Noncontinuous Clock Mode

The size of the incoming packet is defined by the SIZE information of a trace mode packet or the programmed size of a direct data mode packet. If too many or less than the number of bits are received before the next sync signal, the PACKET_ERR_INT flag will be set (Section 36.3.5). In case of receiving a DMMCLK signal without a corresponding DMMSYNC signal, a packet error will also be generated.

Continuous Clock Mode

If less than the expected number of bits are received, the PACKET_ERR_INT flag will be set (Section 36.3.5) when the next DMMSYNC signal is received. Packets with more than the expected number of bits cannot be detected.

The check for packet error is done only after the detection of the first DMMSYNC signal after the DMM is turned on or comes out of suspend mode (with COS = 0; Section 36.3.1), that is, before the reception of first DMMSYNC, the toggling of DMMCLK would be ignored.



36.2.3.3 Bus Error

If an error occurs on the microcontroller internal bus system while transferring the data from the DMM to the destination, the BUSERROR flag will be set.

36.2.4 Interrupts

The module provides different interrupts. These can be programmed to different interrupt levels independently using DMMINTLVL (Section 36.3.4).

Figure 36-6. Interrupt Structure

Interrupts can be divided into error interrupts and functional interrupts. The error handling is described in Section 36.2.3. Functional interrupts depend on the mode (Trace Mode, Direct Data Mode) the DMM module is used in.

Trace Mode: An interrupt can be enabled whenever an access to the lowest address of a defined region is performed. This address is the starting address programmed in the DMMDESTxREGy register. An interrupt for each of the region can be generated by setting the individual interrupt enable bits.

Direct Data Mode: There are two interrupts that can be individually controlled. One is generated when the buffer pointer reaches the end of the defined buffer and wraps around (EO_BUFF; Section 36.3.2). The other one is generated when the buffer pointer matches the programmed interrupt threshold (PROG_BUFF; Section 36.3.2). The buffer pointer points to the next address to be written, therefor there are (interrupt threshold - 1) values stored in the buffer. The interrupt threshold can be programmed in the DMMINTPT register (Section 36.3.11).

36.3 Control Registers

This section describes the DMM registers. The registers support 8, 16, and 32-bit writes. The offset is relative to the associated peripheral select. Table 36-6 provides a summary of the registers and their bits. The base address of the DMM module registers is FFFF F700h.

Table 36-6. DMM Registers

Offset	Acronym	Register Description	Section

Reserved		BUSY
R-0		R-0

23	19	18	17	16
Reserved		CONTCLK	COS	RESET
R-0		R/WP-0	R/WP-0	R/WP-0

15	11	10	9	8
Reserved		DDM_WIDTH		TM_DDM
R-0		R/WP-0		R/WP-0

7	4	3	0
Reserved		ON/OFF	
R-0		R/WP-5h	

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 36-7. DMM Global Control Register (DMMGLBCTRL) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads returns 0. Writes have no effect.
24	BUSY		Busy indicator.
		0	The DMM does not currently receive data and has no data in its internal buffers, which needs to be transferred.
		1	The module is currently receiving data, or has data in its internal buffers.
23-19	Reserved	0	Reads returns 0. Writes have no effect.
18	CONTCLK		Continuous DMMCLK input.
			User and privilege mode read, privilege mode write:
		0	DMMCLK is expected to be suspended between two packets.
		1	DMMCLK is expected to be free running between packets.
17	COS		Continue on suspend. Influences behavior of module while in debug mode. In all cases the corresponding interrupt will be set.
			User and privilege mode (read):
		0	Packets will not be received during debug mode. Before entering debug mode, the ongoing reception of a packet will be finished and the value will be written to the destination.
		1	Continue receiving packets and update destination, while in debug mode.
			Privilege mode (write):
		0	Disable data reception while in debug mode.
		1	Enable data reception while in debug mode.
16	RESET		Reset. This bit resets the state machine and the registers to its reset value, except the RESET bit itself. It must be cleared by writing to it.
			User and privilege mode (read):
		0	No reset of DMM module.
		1	Reset of DMM module.
			Privilege mode (write):
		0	No reset of DMM module.
		1	Reset DMM module to its reset state.
15-11	Reserved	0	Reads returns 0. Writes have no effect.

Copyright © 2018, Texas Instruments Incorporated

Table 36-7. DMM Global Control Register (DMMGLBCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
10-9	DDM_WIDTH		Packet Width in direct data mode.
			User and privilege mode read and privilege mode write operation:
		Bit Encoding	Transfer Size
		0	8 bit
		1h	16 bit
		2h	32 bit
		3h	Reserved
8	TM_DMM		Packet Format.
			User and privilege mode (read):
		0	The DMM module assumes packets in trace mode definition.
		1	The DMM module assumes packets in direct data mode definition.
			Privilege mode (write):
		0	Enable trace mode.
		1	Enable direct data mode.
7-4	Reserved	0	Reads returns 0. Writes have no effect.
3-0	ON/OFF		Switch module on or off
			User and privilege mode (read):
		All other	The DMM module does not receive data.
		Ah	The DMM module receives data and writes it to the buffer.
			Privilege mode (write):
		All other	Disable receive/write operations. Packets in reception, will still be finished.
		Ah	Enable receive/write operations. Packets will be received 1 HCLK cycle after enabling the module.

NOTE: It is recommended to write 5h to ON/OFF to avoid having a soft error inadvertently enabling the module when a single bit flips.

NOTE: Registers that affect the operation of the module, should be only programmed when the BUSY bit is 0 and the ON/OFF bits are not Ah.

NOTE: If the module was in operation, turned off (ON/OFF = all other than Ah) and then turned on (ON/OFF = Ah) again, it is recommended to perform a reset (RESET = 1) of the module before switching it on. This avoids that the state machine is held in an unrecoverable state.

NOTE: A write to these register bits while receiving a packet will not have any effect on the received packet. The mode change will be performed after the packet is received

		0	No interrupt will be generated.
		1	An interrupt will be generated on a write to the start address of this region.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
13	DEST2REG2		**Destination 2 Region 2 Interrupt Set.** This enables the interrupt generation in case data was accessed at the start address of Destination 2 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated on a write to the start address of this region.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
12	DEST2REG1		**Destination 2 Region 1 Interrupt Set.** This enables the interrupt generation in case data was accessed at the start address of Destination 2 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated on a write to the start address of this region.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
11	DEST1REG2		**Destination 1 Region 2 Interrupt Set.** This enables the interrupt generation in case data was accessed at the start address of Destination 1 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated on a write to the start address of this region.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
10	DEST1REG1		**Destination 1 Region 1 Interrupt Set.** This enables the interrupt generation in case data was accessed at the start address of Destination 1 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated on a write to the start address of this region.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
9	DEST0REG2		**Destination 0 Region 2 Interrupt Set.** This enables the interrupt generation in case data was accessed at the start address of Destination 0 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated on a write to the start address of this region.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).

Table 36-8. DMM Interrupt Set Register (DMMINTSET) Field Descriptions (continued)

Bit	Field	Value	Description
8	DEST0REG1		**Destination 0 Region 1 Interrupt Set.** This enables the interrupt generation in case data was accessed at the start address of Destination 0 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
7	BUSERROR		Bus Error Response for errors generated when doing internal bus transfers.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
6	BUFF_OVF		**Buffer Overflow.** This enables the interrupt generation in case new data is received, while the previous data still has not been transmitted.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
5	SRC_OVF		**Source Overflow.** This enables an interrupt if the external system experienced and overflow that was signaled in the Trace Mode packet.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
4	DEST3_ERR		**Destination 3 Error.** This enables the interrupt generation in case data should be written into a address not specified by DMMDEST3REG1/DMMDEST3BL1 or DMMDEST3REG2/DMMDEST3BL2. If both blocksizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).

Table 36-8. DMM Interrupt Set Register (DMMINTSET) Field Descriptions (continued)

Bit	Field	Value	Description
3	DEST2_ERR		**Destination 2 Error Interrupt Set.** This enables the interrupt generation in case data should be written into a address not specified by DMMDEST2REG1/DMMDEST2BL1 or DMMDEST2REG2/DMMDEST2BL2. If both blocksizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
2	DEST1_ERR		**Destination 1 Error Interrupt Set.** This enables the interrupt generation in case data should be written into a address not specified by DMMDEST1REG1/DMMDEST1BL1 or DMMDEST1REG2/DMMDEST1BL2. If both blocksizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
1	DEST0_ERR		**Destination 0 Error Interrupt Set.** This enables the interrupt generation in case data should be written into a address not specified by DMMDEST0REG1/DMMDEST0BL1 or DMMDEST0REG2/DMMDEST0BL2. If both blocksizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).
0	PACKET_ERR_INT		**Packet Error.** This enables the interrupt generation in case of an error condition in the packet reception. Please refer to Section 36.2.3 for the error conditions.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated.
			Privilege mode (write):
		0	No influence on bit.
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).

Table 36-9. DMM Interrupt Clear Register (DMMINTCLR) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads returns 0. Writes have no effect.
17	PROG_BUFF		**Programmable Buffer Interrupt Set.**This disables the interrupt generation in case the buffer pointer equals the programmed value in the DMMINTPT register (Section 36.3.11). This bit is only relevant in Direct Data Mode.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated on pointer match.
			Privilege mode (write):
		0	No influence on bit.
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).
16	EO_BUFF		**End of Buffer Interrupt Set.**This disables the interrupt generation in case data was written to the last entry in the buffer and the pointer wrapped around to the beginning of the buffer. This bit is only relevant in Direct Data Mode.
			User and privilege mode (read):
		0	No interrupt will be generated.
		1	An interrupt will be generated on writing to the last entry.
			Privilege mode (write):
		0	No influence on bit.
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).

36.3.6 DMM Interrupt Offset 1 Register (DMMOFF1)

This register holds the offset indicating which interrupt occurred on interrupt level 0. The CPU can read this register to determine the source of the interrupt without having to test individual interrupt flags.

Figure 36-12. DMM Interrupt Offset 1 Register (DMMOFF1) [offset = 14h]

LEGEND: R = Read only; -*n* = value after reset

Table 36-12. DMM Interrupt Offset 1 Register (DMMOFF1) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Read returns 0. Writes have no effect.
4-0	OFFSET		User and privilege mode (read):
		Bit Encoding	Interrupt
		0	Phantom. All interrupt flags have been cleared before the offset register has been read.
		1h	Packet Error
		2h	Destination 0 Error
		3h	Destination 1 Error
		4h	Destination 2 Error
		5h	Destination 3 Error
		6h	Source Overflow
		7h	Buffer Overflow
		8h	Bus Error

36.3.8 DMM Direct Data Mode Destination Register (DMMDDMDEST)

This register defines the starting address of the buffer used to store the received data in Direct Data Mode. By writing to this register, the DMMDDMPT register (Section 36.3.10) will be set to 0x0000.

Figure 36-14. DMM Direct Data Mode Destination Register (DMMDDMDEST) [offset = 1Ch]

Bit	Field	Value	Description
31-15	Reserved	0	Read returns 0. Writes have no effect.
14-0	POINTER		These bits hold the pointer to the next entry to be written in the buffer. The pointer points to the byte aligned address. If in 16-bit DDM mode, bit 0 will be 0. If in 32-bit DDM mode, bit 0 and 1 will be 0. User and privilege mode (read): next data entry Privilege mode (write): writes have no effect

36.3.11 DMM Direct Data Mode Interrupt Pointer Register (DMMINTPT)

This register can be programmed to hold a threshold to which the DMMDDMPT register (Section 36.3.10) is compared. An interrupt can be generated when both match.

31-15	Reserved	0	Read returns 0. Writes have no effect.
14-0	INTPT		Interrupt Pointer. When the buffer pointer (Section 36.3.10) matches the programmed value in DMMINTPT and the PROG_BUF interrupt (Section 36.3.2) is set, an interrupt is generated. User and privilege mode (read): current interrupt threshold Privilege mode (write): new interrupt threshold

Copyright © 2018, Texas Instruments Incorporated

36.3.12 DMM Destination x Region 1 (DMMDESTxREG1)

This register defines the starting address of the buffer used to store the received data in Trace Mode. If the received data does not fall into the address range defined by DMMDESTxREG1 and DMMDESTxBL1, an interrupt (DESTx_ERR) can be generated. The description below is valid for following registers: DMMDEST0REG1, DMMDEST1REG1, DMMDEST2REG1, DMMDEST3REG1.

36.3.16 DMM Pin Control 0 (DMMPC0)

This register defines if the DMM pins are used in functional or GIO mode. It should only be written when ON/OFF = 0101 and the BUSY bit = 0 (Section 36.3.1). If pins other than the pins specified in Table 36-5 are configured, or DMMCLK and DMMSYNC are programmed as non-functional pins, no operation in trace mode or direct data mode is possible.

36.3.20 DMM Pin Control 4 (DMMPC4)

This register allows to set individual pins to a logic high level without having to do a read-modify-write operation as would be the case with the DMMPC3 register (Section 36.3.19). Writing a zero to a bit will not change the state of the pin.

36.3.21 DMM Pin Control 5 (DMMPC5)

This register allows to set individual pins to a logic low level without having to do a read-modify-write operation as would be the case with the DMMPC3 register (Section 36.3.19). Writing a one to a bit will change the output to a logic low level, writing a zero will not change the state of the pin.

RAM Trace Port (RTP)

This chapter describes the functionality of the RAM trace port (RTP) module. It allows the capability to perform data trace of a CPU or other master accesses to the internal RAM and peripherals.

Topic **Page**

37.1 Overview **2155**
37.2 Module Operation **2157**
37.3 RTP Control Registers **2163**

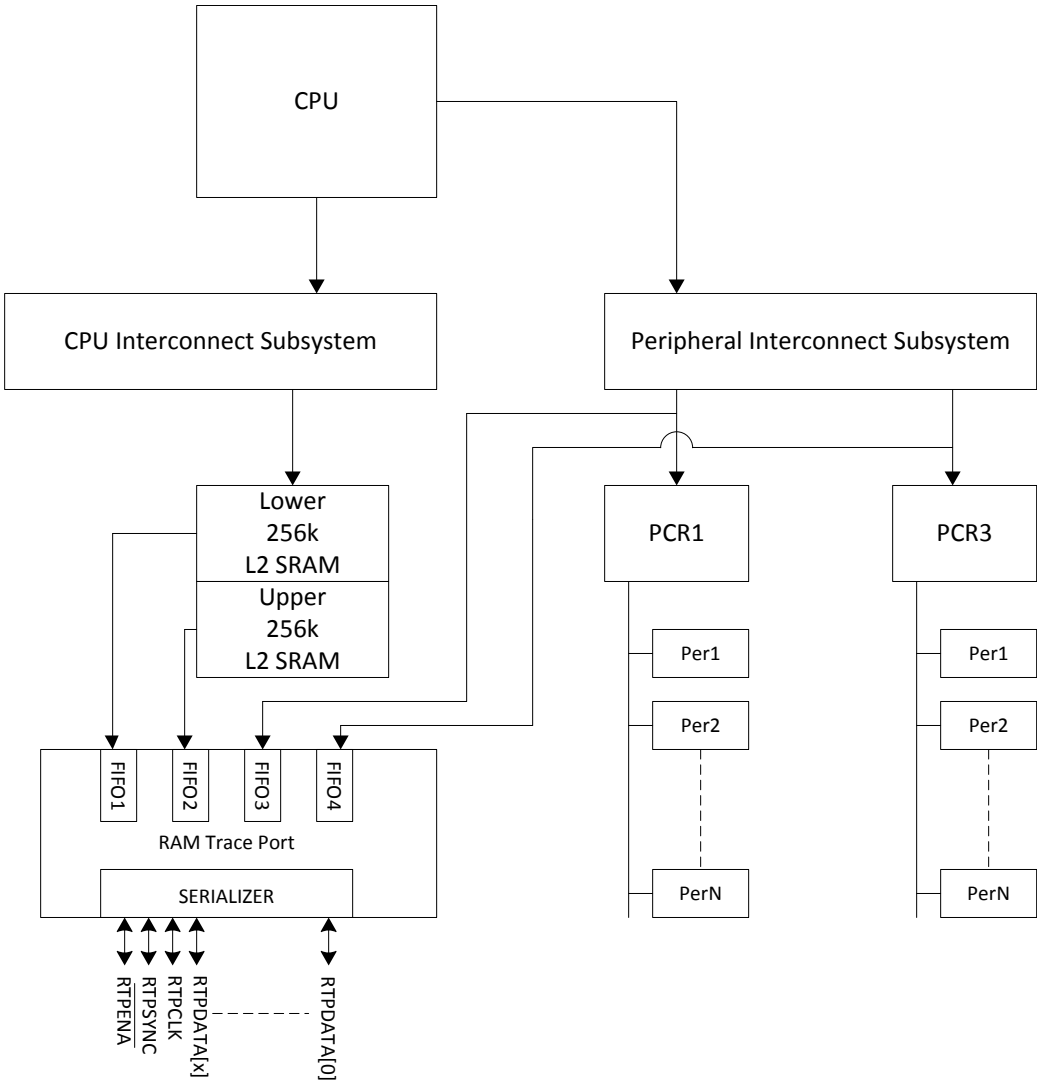
Copyright © 2018, Texas Instruments Incorporated

37.1 Overview

This document describes the functionality of the RAM trace port (RTP) module, which provides the features to datalog the RAM contents of the devices or accesses to peripherals without program intrusion. It can trace all data write or read accesses to internal RAM. In addition, it provides the capability to directly transfer data to a FIFO to support a CPU-controlled transmission of the data. The trace data is transmitted over a dedicated external interface.

37.1.1 Features

The RTP offers the following features:



- Two modes of operation - Trace Mode and Direct Data Mode
  - Trace Mode (Section 37.2.1)
    - Non-intrusive data trace on write or read operation
    - Visibility of RAM content at any time on external capture hardware
    - Trace of peripheral accesses
    - 2 configurable trace regions for each RAM module to limit amount of data to be traced
    - FIFO to store data and address of data of multiple read/write operations
    - Trace of CPU and/or DMA accesses with indication of the master in the transmitted data packet
  - Direct Data Mode (Section 37.2.2)
    - Directly write data with the CPU or trace read operations to a FIFO, without transmitting header and address information
- Dedicated synchronous interface to transmit data to external devices
- Free-running clock generation or clock stop mode between transmissions
- up to 100 Mbit per sec/pin transfer rate for transmitting data (up to 100MB/s; see device datasheet for maximum transmission clock frequency)
- Pins not used in functional mode can be used as GIOs

37.1.2 Block Diagram

Figure 37-1 is a block diagram of the RTP.

Figure 37-1. RAM Trace Port Module Block Diagram

Copyright © 2018, Texas Instruments Incorporated

37.2 Module Operation

The RTP module has two modes of operation: Trace Mode and Direct Data Mode.

37.2.1 Trace Mode

This mode traces all write or read accesses of CPU and/or a different master to the internal RAMs and the peripheral bus, if the access falls into one of the programmed trace regions. The trace regions allow to restrict the amount of data which is traced. This is done by specifying the start address and the size of the region to be traced. It is not possible to trace write and read operations in the same region at the same time.

Whenever a write or read access occurs, the address, data, size of the access (8, 16, 32, 64 bit), and which module initiated the write or read operation is captured into the FIFO of the corresponding RAM frame. Once new data is in the FIFO and the serializer is empty, the RTP transmits the data into the serializer and starts transmitting it.

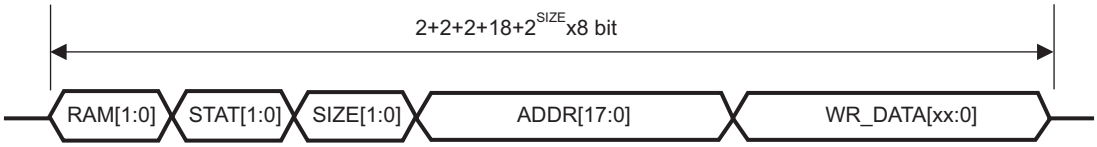
The FIFOs are shifting data into the serializer in a round-robin scheme. This means if data is available in multiple FIFOs, the sequence for shifting data into the serializer is FIFO1, FIFO2, FIFO3 and then FIFO4. Only one entry in the respective FIFO is provided to the serializer before switching to the next FIFO. If a FIFO does not hold new data, it will be skipped. This scheme ensures that the FIFOs are drained uniformly.

NOTE: This device implements Level 1 cache memory. Reading and writing from/to Level 2 RAMs which is declared Cacheable can result in RAM traces that do not correspond to the software's original intent. Reading from Level 2 RAMs which is declared Cacheable will not result in any load transaction if the address is a hit in the level 1 cache memory. If a write-through with allocate on reads policy is selected and a cache miss happens, the cache controller will also allocate (load) the matching cache line from level 2 RAM after the data is written to the Level 2 RAM. This load due to the allocate on reads policy will result in the read data being traced.

37.2.1.1 Packet Format in Trace Mode

Figure 37-2 and Figure 37-3 illustrate this format.

Figure 37-2. Packet Format Trace Mode for RAM Locations



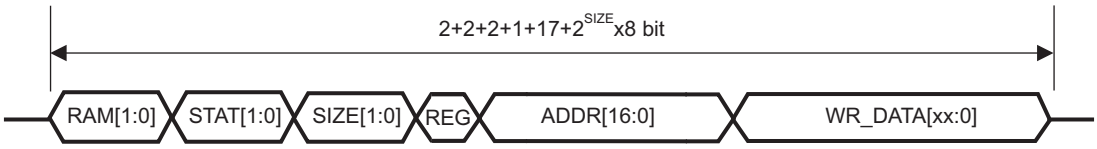


Figure 37-3. Packet Format Trace Mode for Peripheral Locations

When RAM locations are traced, one packet consists of two bits denoting the RAM block in which the data is stored or if the access has been to a peripheral location (Table 37-1), two status bits showing the access initiator or if there was a FIFO overflow (Table 37-2), two bit size (8, 16, 32, or 64 bit) information of the data (Table 37-3), the 18-bit address for RAM accesses and $2^{SIZE} \times 8$ bits of data. If a peripheral location is traced, then the effective address reduces to 17 bits(ADDR[16:0]) and a separate bit (REG) between the SIZE information and the address denotes which programmable region has traced this peripheral access (Table 37-4). With the region identifier, the external hardware can determine which peripheral was traced.

Table 37-1. Encoding of RAM Bits in Trace Mode Packet Format

RAM[1:0]	RAM
0	Level 2 lower 256kB RAM
1h	Level 2 upper 256kB RAM
2h	Peripherals under PCR1
3h	Peripherals under PCR3

Table 37-2. Encoding of Status Bits in Trace Mode Packet Format

STAT[1:0]	Status
0	Normal entry CPU1
1h	Normal entry other Master
2h	Normal entry CPU2
3h	Overflow of the dedicated FIFO

In the event of a FIFO overflow, an overflow will be signaled in the status bits of the next transmitted packet of that particular FIFO. The last entry in the FIFO will not be overwritten by the new data.

Table 37-3. Encoding of SIZE bits in Trace Mode Packet Format

SIZE[1:0]	Write/Read Size
0	8 bit
1h	16 bit
2h	32 bit
3h	64 bit

Table 37-4. Encoding of REG in Trace Mode Packet Format

REG	Region
0	1
1	2

The packet will be split up into several subpackets when transmitted over the RTP port pins depending on the port width configured. The port width is configured with bits PW[1:0] in the RTPGLBCTRL register (Section 37.3.1). For certain port width configurations and write/read sizes, the number of bits in a packet does not exactly match the port width for the last subpacket. The remaining bits will be filled with zeros.

Table 37-5. Number of Transfers/Packet

Port Width	Write/Read Size in bits			
	8	16	32	64
2	16 --> 16	20 --> 20	28 --> 28	44 --> 44
4	8 --> 8	10 --> 10	14 --> 14	22 --> 22
8	4 --> 4	5 --> 5	7 --> 7	11 --> 11
16	2 --> 2	2.5 --> 3	3.5 --> 4	5.5 --> 6

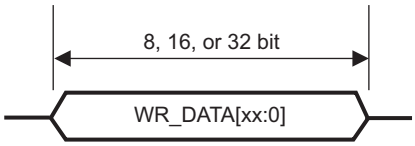
Copyright © 2018, Texas Instruments Incorporated

Example: For a 16-bit port and with data of 16-bit, the last transfer has to be padded with eight 0s. This effectively results in a transfer of 48 bits instead of 40. However the whole transfer is completed in 3 RTPCLK cycles.

For a detailed description of the representation of the packet on the RTP port pins, refer to Section 37.2.5.

37.2.2 Direct Data Mode (DDM)

In this mode, data is written directly by the CPU or other master to a dedicated capture register (RTPDDMW). The data is then transferred from the capture register to the FIFO. In a different configuration the module traces the data on read operations on the RAM directly into the FIFOs. In Direct Data Mode, no information other than the actual data is transmitted. The address of the written data can only be determined by the order of writes or reads by the CPU or other master. This mode is especially useful if a block of data on consecutive addresses has to be transmitted.



The transfer size (8, 16, or 32 bit) is programmable, but cannot be dynamically changed. Data not written/read in the correct transfer size will be truncated/extended. For example, if the transfer size is programmed to 16 bits and a 32-bit write operation is performed, the data written to the FIFO will be 32-bit wide, however only the upper 16 bits of the FIFO will be transmitted. If an 8-bit operation is performed, bits 8-15 of the FIFO will be indeterminate, so the upper 8 bits of the data transmitted are dependent on the previous contents of the FIFO RAM.

When the module is configured in Direct Data Mode (TM_DDM = 1) to trace write operations (DDM_RW = 1) to the RTPDDMW register, the programming of the trace regions for all FIFOs will be ignored and data tracing, when accessing the addresses defined by the regions, will not occur. If the module is configured in read mode (DDM_RW = 0), and if the read access to a RAM block falls into a valid trace region, the data will be traced into the corresponding FIFO for this RAM block. Since no address information is transmitted in Direct Data Mode, the executing program has to make sure that one FIFO is completely empty (RTPGSR register), before new data is traced into the next FIFO.

37.2.2.1 Packet Format in Direct Data Mode

In Direct Data Mode write or read operations, only the data written to the RTP direct data mode write register (RTPDDMW) or the data read from RAM, and therefore captured into the FIFO, will be transmitted. The packet length is programmable (8, 16, or 32 bits). Figure 37-4 illustrates this format.

Figure 37-4. Packet Format in Direct Data Mode

37.2.3 Trace Regions

To limit the amount of data to be trace, two trace regions per RAM or peripheral are implemented. These can be programmed to specific start addresses and block sizes. Depending on the device configuration (number of RAM blocks), not all regions might be implemented. Trace regions are used in Trace Mode for read or write trace and in Direct Data Mode for read trace. In Direct Data Mode write configuration, the data has to be written directly to the RTP direct data mode write register (RTPDDMW).

The RAM and peripherals start at fixed addresses in the devices memory map. With this the start address of a region does not need to be specified with its full 32-bit address. For RAM regions, only the lower 18-bit need to be programmed. The peripheral address frame covers a wider range and the start address needs to be programmed with the lower 24-bit.

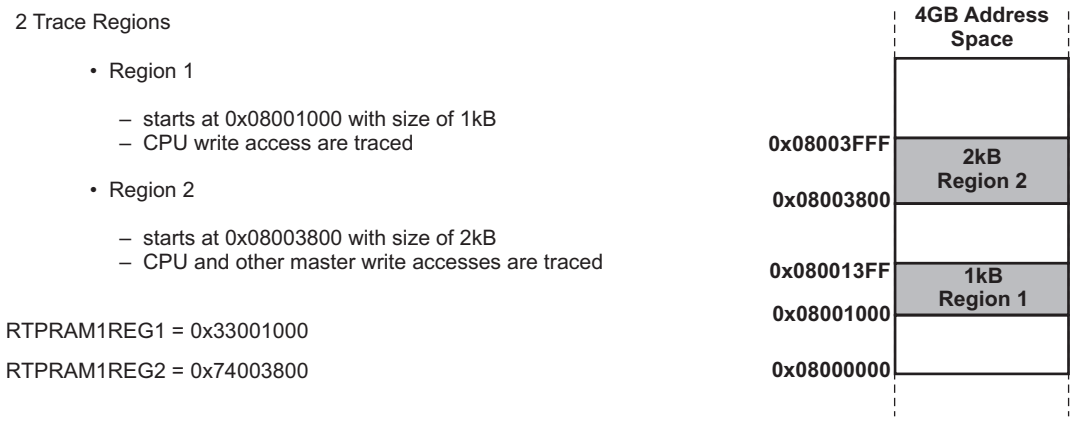
The trace regions do not support a programmable end address; however, a block size needs to be specified for each region. The block size can be chosen from as low as 256 Bytes up to 256 kBytes (128 kBytes for peripherals).

Copyright © 2018, Texas Instruments Incorporated

37.2.3.1 Inverse Trace Regions

The RTP can be configured to trace accesses which fall into, or are made outside of the specified regions. This can be accomplished by the INV_RGN bit. If this bit is 0, all access which are made inside a region are traced. If the bit is 1, all accesses outside the region are traced. The INV_RGN bit affects all regions of the RTP, see the RTP global control register (RTPGLBCTRL).

There are certain restrictions when using INV_RGN = 1:



- In this mode up to 2 regions can be excluded from tracing accesses to a particular RAM.
- Inverse trace regions with one or both regions of a RAM programmed with blocksize = 0 is not supported. If only one address range should be excluded from the trace, either the address range has to be covered by both regions (e.g. excluding 1kB range with two 512B regions), or both regions have to be programmed with the same start address and region size. If the whole RAM should be traced, inverse region mode should not be used, instead the 2 regions could be programmed to cover the entire address range with INV_RGN = 0.
- Both regions have to define the same access rights (bits CPU_DMA and RW; see Section 37.3.4) for accesses outside of the region of each RAM block, otherwise the result is undefined.
- Peripheral trace in inverse region mode is not supported. The 16 MByte peripheral address range cannot be covered entirely by the 17 bit address definition of the RTP protocol.

37.2.3.2 Overlapping Trace Regions

When in INV_RGN = 0 mode with both regions overlapping and an access is done into the overlapping address range, both regions will be checked for their access rights and if one or both is satisfied, the access will be traced. In the case that both regions would allow the data to be traced, there will still be only one entry into the FIFO.

If accesses to peripherals are done within overlapping regions, the REG bit in the protocol will be 0, denoting Region 1 (see Section 37.2.1.1).

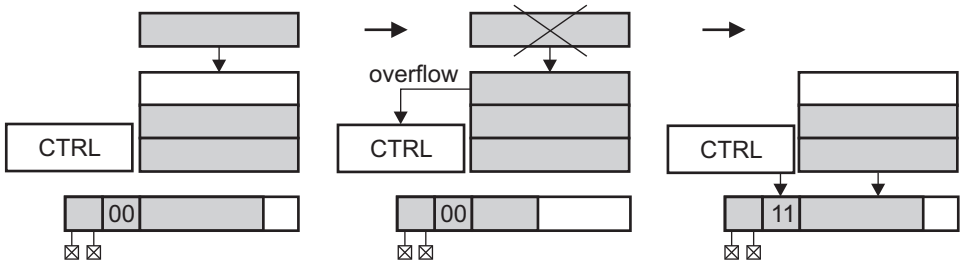
Figure 37-5. Example for Trace Region Setup

Copyright © 2018, Texas Instruments Incorporated

37.2.3.3 Cortex-R5 Specifics

Considerations/Restrictions

- Reading and writing from/to Level 2 RAMs which is declared Cacheable can result in RAM traces that do not correspond to the software's original intent.
- A store instruction to Non-cacheable, or write-through Normal memory might not result in an AXI transfer to the Level 2 RAMs or peripherals because of the merging of store in the internal buffers.



37.2.4 Overflow/Empty Handling

In case the application does RAM accesses faster than the FIFO can be emptied via the external pin interface, the FIFO can overflow. You can choose whether the program execution/data transfer should be suspended, or an overflow should be signaled in the status bits of the next, to be transmitted, message of this particular FIFO. If program execution is resumed, the data will be lost. The overflow will not be signaled in the message that is already in the serializer and being transmitted when the overflow occurs.

NOTE: The status information will only be transmitted in Trace Mode, since the Direct Data Mode packet does not contain any status information.

When an overflow in a FIFO occurs, the corresponding bit in the RTP global status register (RTPGSR) will be set.

Figure 37-6. FIFO Overflow Handling

37.2.5 Signal Description

Table 37-6 lists the signals of the RTP.

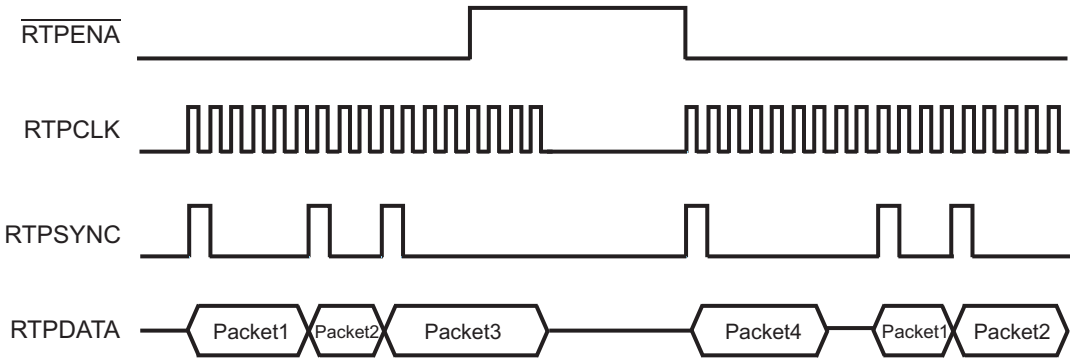
Table 37-6. RTP Signals

Signal	Description
RTPCLK	This clock signal is used to clock out the data of the serializer. Depending on the CONTCLK bit, the clock can be suspended between packets or it can be free running. The RTPCLK frequency can be adjusted by the PRESCALER bits (see RTP global control register (RTPGLBCTRL).
RTPSYNC	The module provides a packet-sync signal. This signal will go high on the rising edge of RTPCLK and will be valid for one RTPCLK cycle to synchronize external hardware to the data stream. The RTPSYNC pulse will be generated for each new packet.
$\overline{\text{RTPENA}}$	This signal is an input and can be used by external hardware to stop the data transmission between packets. When the $\overline{\text{RTPENA}}$ signal goes high, the RTP will finish the current packet transmission and then stop. Once the signal is pulled low again, the RTP will resume the transfer if data is still present in the serializer or FIFOs. The $\overline{\text{RTPENA}}$ signal does not have to be used for proper module operation. It can be used in GIO mode if the external hardware cannot generate this signal. Overflows of the external system cannot be handled in this case.
RTPDATA[15:0]	These pins are used to do the actual data transfer. Data changes with the rising edge of RTPCLK. The port can be configured for different widths (PW[1:0]). The minimum port width supported is 2 pins. See Table 37-10 which pins are used for the port.

Copyright © 2018, Texas Instruments Incorporated

Figure 37-7 shows an example of multiple packet transmissions in Trace Mode with an interruption between packets because of RTPENA pulled high.

Figure 37-7. RTP Packet Transfer with Sync Signal



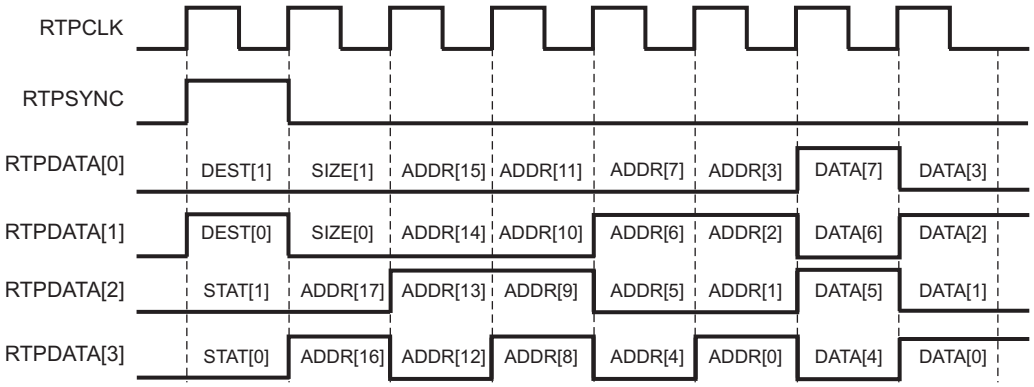


Figure 37-8 shows an example of a 4-bit data port with 8-bit write data (A5h) written into RAM1 (address 12345h) with no overflow in trace mode.

Figure 37-8. Packet Format in Trace Mode

37.2.6 Data Rate

The module is configurable to support different RTPCLK frequencies. See the device datasheet for the maximum supported frequency. HCLK will be prescaled to achieve the desired RTPCLK frequency. The prescaler supports prescale values from 1 to 8, using the RTP global control register (RTPGLBCTRL).

The effective bandwidth depends on the configuration of the module and the average data width transmitted in the packets.

Copyright © 2018, Texas Instruments Incorporated

37.2.7 GIO Function

Pins which are not used for RTP functionality can be used as normal GIO pins. If pins should be used in functional mode or GIO mode, they can be programmed in the RTP pin control 0 register (RTPPC0). The direction of the pins can be chosen in the RTP pin control 1 register (RTPPC1).

Module pins can have either an internal pullup or active pulldown that makes it possible to leave the pins unconnected externally when configured as inputs. The pins can be programmed to have the active pull capability by writing a 0 to the corresponding bit in the RTP pin control 7 register (RTPPC7). Writing a 1 to the corresponding bit disables the active pull functionality of the pin. A pull up can be configured by writing 1 to the corresponding bit in the RTP pin control 8 register (RTPPC8). Writing 0 will activate the pulldown capability. The pullup/pulldown is deactivated when a bidirectional pin is configured as an output. If the pullup/down capability is disabled (RTPPC7) and the pull is configured as pulldown (RTPPC8), the input buffer will be disabled.

The GIO pin can be configured to include an open drain functionality when they are configured as output pins. This is done by writing a 1 into the corresponding bit of the RTP pin control 6 register (RTPPC6). When the open drain functionality is enabled, a zero written to the data output register (RTPPC3) forces the pin to a low output voltage (V_{OL} or lower), whereas writing a 1 to the data output register (RTPPC3) forces the pin to a high impedance state. The open drain functionality is disabled when the pin is configured as an input pin.

37.3 RTP Control Registers

Table 37-7 lists the RTP module registers. The registers support 8-, 16-, and 32-bit writes. The base address of the RTP module is FFFF FA00h.

Table 37-7. RTP Control Registers

Offset	Acronym	Register Description	Section
00h	RTPGLBCTRL	RTP Global Control Register	Section 37.3.1

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 37-8. RTP Global Control Register (RTPGLBCTRL) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	TEST		By setting the bit, the FIFO RAM will be mapped into the SYSTEM Peripheral frame starting at address 0xFFF83000. Each FIFO starts at a 1-k boundary. Each FIFO entry is aligned to a 128-bit boundary. See Table 37-9 for a listing of the FIFOs and their corresponding addresses.
			Read:
		0	FIFO RAM is not accessible in the memory-map.
		1	FIFO RAM is mapped to address FFF8 3000h.
			Write in Privilege:
		0	Disables mapping of the FIFO RAM.
		1	Enables mapping of the FIFO RAM into address FFF8 3000h.
18-16	PRESCALER		The prescaler divides HCLK down to the desired RTPCLK frequency. The maximum RTPCLK frequency specified in the device datasheet must not be exceeded. No dynamic change of RTPCLK is supported. The module should be switched off by the ON/OFF bits in this register before changing the prescaler.
			User and privilege mode read, privilege mode write:
		0	Prescaler is HCLK/1.
		1h	Prescaler is HCLK/2.
		2h	Prescaler is HCLK/3.
		3h	Prescaler is HCLK/4.
		4h	Prescaler is HCLK/5.
		5h	Prescaler is HCLK/6.
		6h	Prescaler is HCLK/7.
		7h	Prescaler is HCLK/8.
15-14	Reserved	0	Reads return 0. Writes have no effect.
13-12	DDM_WIDTH		Direct data mode word size width. This bit field configures the number of bits that will be transmitted in Direct Data Mode.
			User and privilege mode read, privilege mode write:
		0	Word size width is 8 bits.
		1h	Word size width is 16 bits.
		2h	Word size width is 32 bits.
		3h	Reserved

Copyright © 2018, Texas Instruments Incorporated

Table 37-8. RTP Global Control Register (RTPGLBCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
11	DDM_RW		Direct data mode.
			Read:
		0	Read tracing in Direct Data Mode is enabled.
		1	Write tracing in Direct Data Mode to DDMW register is enabled.
			Write in Privilege:
		0	Enable read tracing in Direct Data Mode. The RW bits in the RTPRAMxREGy registers to be ignored.
		1	Write tracing in Direct Data Mode to DDMW register is enabled. The RW bits in the RTPRAMxREGy registers are to be ignored.
10	TM_DDM		Trace Mode or Direct Data Mode.
			Read:
		0	Module is configured in Trace Mode.
		1	Module is configured in Direct Data Mode.
			Write in Privilege:
		0	Configure module to Trace Mode.
		1	Configure module to Direct Data Mode.
9-8	PW		Port width. This bit field configures the RTP to the desired port width. Pins that are not used for functional mode can be used as GIO pins. See Table 37-10 for which pins are used for the port.
		0	RTP is 2 pins wide.
		1h	RTP is 4 pins wide.
		2h	RTP is 8 pins wide.
		3h	RTP is 16 pins wide.
7	RESET		This bit resets the state machine and the registers to their reset value. This reset ensures that no data left in the FIFOs is shifted out after switching on the module with the ON/OFF bit.
			Read:
		0	RTP module is out of reset.
		1	RTP module is in reset.
			Write in Privilege:
		0	Do not reset the module.
		1	Reset the module.
6	CONTCLK		Continuous RTPCLK enable.
			Read:
		0	RTPCLK is stopped between transmissions.
		1	RTPCLK is free running.
			Write in Privilege:
		0	Stop RTPCLK between transmissions.
		1	Configure RTPCLK as free running.
5	HOVF		Halt on overflow. This bit indicates whether the CPU or DMA is halted while only one location in the FIFO is empty in Trace Mode or Direct Data Mode (read).
			Read:
		0	Current data transfer to the FIFO will not be suspended in case of a full FIFO.
		1	Current data transfer to the FIFO will be suspended in case of a full FIFO.
			Write in Privilege:
		0	The halt on FIFO overflow will be disabled. The data transfer will not be suspended and will be discarded. Data written to the RTPDDMW register will overwrite the RTPDDMW register.
		1	The halt on FIFO overflow will be enabled. Data written to the already full FIFO will be written once the FIFO is emptied again. The data transfer to the FIFO will be suspended and signaled to the CPU or other master while there is still data to be shifted out. When there is an empty FIFO location again, the transfer of the data to the FIFO will be finished.

Table 37-8. RTP Global Control Register (RTPGLBCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
4	INV_RGN		Trace inside or outside of defined trace regions.
			Read:
		0	Accesses inside the trace regions are traced.
		1	Accesses outside the trace regions are traced.
			Write in Privilege:
		0	Allow tracing of accesses inside the regions set in RTPRAMxREGy.
		1	Allow tracing of accesses outside the regions set in RTPRAMxREGy.
3-0	ON/OFF		ON/Off switch.
			Read:
		Ah	Tracing of data is enabled.
		All other values	Tracing of data is disabled.
			Write in Privilege:
		Ah	Enable Tracing of data. If there is any previous captured data remaining, it will be shifted out.
		All other values	Disable tracing of data. If there is still data left in the shift register, it will be shifted out before disabling the shift operations. The data captured in the FIFO remains there until the ON/OFF bits are set to Ah.
			NOTE: It is recommended to write 5h to disable the module to prevent a soft error from enabling the module inadvertently by a single bit flip.

Table 37-9. FIFO Corresponding Addresses

FIFO	Address
1	FFF8 3000h
2	FFF8 3400h
3	FFF8 3800h
4	FFF8 3C00h

Table 37-11. RTP Trace Enable Register (RTPTRENA) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	ENA4		Enable tracing for peripherals under PCR3. This bit enables tracing into FIFO4 in trace mode (read/write) or direct data mode (read) operations. In Direct Data Mode write operations, this bit is ignored and tracing into FIFO4 is disabled.
			Read:
		0	Tracing is disabled.
		1	Tracing is enabled.
			Write in Privilege:
		0	Disable tracing. If RTPGLBCTRL.ON/OFF = Ah, data already captured in FIFO4 is still transmitted (RTPGLBCTRL).
		1	Enable tracing.
23-17	Reserved	0	Reads return 0. Writes have no effect.
16	ENA3		Enable tracing for peripherals under PCR1. This bit enables tracing into FIFO3 in Trace Mode (read/write) or Direct Data Mode (read) operations. In Direct Data Mode write operations, this bit is ignored and tracing into FIFO3 is disabled.
			Read:
		0	Tracing is disabled.
		1	Tracing is enabled.
			Write in Privilege:
		0	Disable tracing. If RTPGLBCTRL.ON/OFF = Ah, data already captured in FIFO3 is still transmitted (RTPGLBCTRL).
		1	Enable tracing.
15-9	Reserved	0	Reads return 0. Writes have no effect.
8	ENA2		Enable tracing for RAM block 2. This bit enables tracing into FIFO2 in Trace Mode (read/write) or Direct Data Mode (read) operations. In Direct Data Mode write operations, this bit is ignored and tracing into FIFO2 is disabled.
			Read:
		0	Tracing is disabled.
		1	Tracing is enabled.
			Write in Privilege:
		0	Disable tracing. If RTPGLBCTRL.ON/OFF = Ah, data already captured in FIFO2 is still transmitted.
		1	Enable tracing.
7-1	Reserved	0	Reads return 0. Writes have no effect.

Table 37-12. RTP Global Status Register (RTPGSR) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reads return 0. Writes have no effect.
12	EMPTYSER		Serializer empty. This bit determines if there is data left in the serializer.
		0	Serializer holds data that is shifted out.
		1	Serializer is empty.
11	EMPTYPER2		Peripheral FIFO empty. This bit determines if there are entries left in the FIFO. FIFO4 is used for tracing peripherals under PCR3.
		0	FIFO4 contains entries.
		1	FIFO4 is empty.
10	EMPTYPER1		Peripheral FIFO empty. This bit determines if there are entries left in the FIFO. FIFO3 is used for tracing peripherals under PCR1.
		0	FIFO3 contains entries.
		1	FIFO3 is empty.
9	EMPTY2		RAM block 2 FIFO empty. This bit determines if there are entries left in the FIFO. FIFO2 is used for tracing the upper 256kB RAM.
		0	FIFO2 contains entries.
		1	FIFO2 is empty.
8	EMPTY1		RAM block 1 FIFO empty. This bit determines if there are entries left in the FIFO. FIFO1 is used for tracing the lower 256kB RAM.
		0	FIFO1 contains entries.
		1	FIFO1 is empty.
7-4	Reserved	0	Reads return 0. Writes have no effect.
3	OVFPER		Overflow peripheral FIFO. This flag indicates that FIFO4 had all locations full and another attempt to write data to it occurred. The bit will not be cleared automatically if the FIFO is emptied again. The bit will stay set until the CPU clears it.
			Read:
		0	No overflow occurred.
		1	An overflow occurred.
			Write in Privilege:
		0	No effect.
		1	Clears the bit.
2	Reserved	0	Reads return 0. Writes have no effect.

37.3.4 RTP RAM 1 Trace Region Registers (RTPRAM1REG[1:2])

Figure 37-12 and Table 37-13 illustrate these registers.

Figure 37-12. RTP RAM 1 Trace Region Registers (RTPRAM1REGn) (offset = 0Ch and 10h)

31 29	28	27 24	23 18	17 16
CPU_DMA	RW	BLOCKSIZE	Reserved	STARTADDR
R/WP-0	R/WP-0	R/WP-0	R-0	R/WP-0

15 0
STARTADDR
R/WP-0

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 37-13. RTP RAM 1 Trace Region Registers (RTPRAM1REGn) Field Descriptions

Bit	Field	Value	Description
31-29	CPU_DMA		When the device is configured in lock-step mode, bit 31 will return 0 and a write has no effect. This bit field indicates if read or write operations are traced either coming from the CPU and/or from the other master.
			User and privilege mode read, privilege mode write:
		0	Read or write operations are traced when coming from the CPU and the other master.
		1h	Read or write operations are traced only when coming from the CPU.
		2h	Read or write operations are traced only when coming from the other non-CPU master.
		3h	Reserved
28	RW		Read/Write. This bit indicates if read or write operations are traced in Trace Mode or Direct Data Mode (read operation). If configured for write in Direct Data Mode (RTPGLBCTRL), the data captured will be discarded. A write operation in Direct Data Mode has to be directly to the RTP direct data mode write register (RTPDDMW) instead of to RAM. Depending on the INV_RGN bit setting, accesses into or outside the region will be traced.
			Read:
		0	Read operations will be captured.
		1	Write operations will be captured.
			Write in Privilege:
		0	Trace read accesses.
		1	Trace write accesses.
27-24	BLOCKSIZE		These bits define the length of the trace region. Depending on the setting of INV_RGN (RTPGLBCTRL), accesses inside or outside the region defined by the start address and blocksize will be traced. If all bits of BLOCKSIZE are 0, the region is disabled and no data will be captured.
			Region size (in bytes):
		0	0
		1h	256
		2h	512
		3h	1K
		4h	2K
		Ah	128K
		Bh	256K
		Ch-Fh	Reserved
23-18	Reserved	0	Reads return 0. Writes have no effect.
17-0	STARTADDR	0-3 FFFFh	These bits define the starting address of the address region that should be traced. The start address has to be a multiple of the block size chosen. If the start address is not a multiple of the block size, the start of the region will begin at the next lower block size boundary.

Table 37-14. RTP RAM 2 Trace Region Registers (RTPRAM2REGn) Field Descriptions

Bit	Field	Value	Description
31-29	CPU_DMA		When the device is configured in lock-step mode, bit 31 will return 0 and a write has no effect. This bit field indicates if read or write operations are traced either coming from the CPU and/or from the other master.
			User and privilege mode read, privilege mode write:
		0	Read or write operations are traced when coming from the CPU and the other master.
		1h	Read or write operations are traced only when coming from the CPU.
		2h	Read or write operations are traced only when coming from the other master.
		3h	Reserved
28	RW		Read/Write. This bit indicates if read or write operations are traced in Trace Mode or Direct Data Mode (read operation). If configured for write in Direct Data Mode (RTPGLBCTRL), the data captured will be discarded. A write operation in Direct Data Mode has to be directly to the RTP direct data mode write register (RTPDDMW) instead of to RAM. Depending on the INV_RGN bit setting, accesses into or outside the region will be traced.
			Read:
		0	Read operations will be captured.
		1	Write operations will be captured.
			Write in Privilege:
		0	Trace read accesses.
		1	Trace write accesses.
27-24	BLOCKSIZE		These bits define the length of the trace region. Depending on the setting of INV_RGN (RTPGLBCTRL), accesses inside or outside the region defined by the start address and blocksize will be traced. If all bits of BLOCKSIZE are 0, the region is disabled and no data will be captured.

37.3.6 RTP RAM 3 Trace Region Registers (RTPRAM3REG[1:2])

FIFO3 was originally designed to support RAM trace limiting to a maximum trace range of 256kB. In this device, FIFO3 is dedicated for tracing the PCR1 peripheral accesses. Peripherals in PCR1 occupy a total address range of 512kB of space. Therefore, it is not possible to trace the entire range of 512kB since there are only 18 bits of address being traced out in the packet. You can use the two trace regions to trace any two areas in the lower half of the PCR1's space from 0xFFF80000 to 0xFFFBFFFF provided there is not an intentional or un-intentional access to the upper half of the space. If you want to trace the upper half of PCR1's space from 0xFFFC0000 to 0xFFFFFFFF then the external hardware/software must reconstruct the full 32-bit address by forcing address bit 18 high and also ensures that there is no intentional or un-intentional accesses to the lower half of the space. Since the external hardware is unable to distinguish between the lower half and the upper half of PCR1, you can not trace both of the halves at the same time.

NOTE: Bit REG (Section 37.2.1.1) in the protocol for peripheral trace will be not be applicable to the PCR1 trace. PCR1 trace follows the RAM trace protocol with 18 bits of address trace out.

Figure 37-14 and Table 37-15 illustrate these registers.

Figure 37-14. RTP RAM 3 Trace Region Registers (RTPRAM3REGn) (offset = 1Ch and 20h)

37.3.7 RTP Peripheral Trace Region Registers (RTPPERREG[1:2])

FIFO4 is dedicated for tracing the PCR3 peripheral accesses. Since the peripheral frame is 16 Mbytes, the start address has to be defined as a 24-bit value. However, only bits 16 to 0 will be transmitted in the protocol. Bit REG (Section 37.2.1.1) in the protocol will be 0 if there was an access to the range defined by RTPPERREG1. REG will be 1 if the access was into the range defined by RTPPERREG2. Figure 37-15 and Table 37-16 illustrate these registers.

Figure 37-15. RTP Peripheral Trace Region Registers (RTPPERREGn) (offset = 24h and 28h)

37.3.8 RTP Direct Data Mode Write Register (RTPDDMW)

The CPU has to write data to this register if the module is used in Direct Data Mode write configuration. Figure 37-16 and Table 37-17 describe this register.

Figure 37-16. RTP Direct Data Mode Write Register (RTPDDMW) (offset = 2Ch)

31	0
DATA	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 37-17. RTP Direct Data Mode Write Register (RTPDDMW) Field Descriptions

Bit	Field	Description
31-0	DATA	This register must be written to in a Direct Data Mode write operation to store the data into FIFO1. Data written must be right-aligned. If the FIFO is full, the reaction depends on the setting of the HOVF bit (RTPGLBCTRL). If the bit is set, the master writing the data will be wait-stated. If the bit is cleared, previous data written to the register will be overwritten. Reads of this register always return 0.

Copyright © 2018, Texas Instruments Incorporated

37.3.9 RTP Pin Control 0 Register (RTPPC0)

This register configures the RTP pins as functional or GIO pins. Once the pin is configured in functional mode, it overrides the settings in the RTPPC1 register. Writing to the RTPPC3, RTPPC4, and RTPPC5 registers will have no effect for pins configured as functional pins. Figure 37-17 and Table 37-18 describe this register.

Figure 37-17. RTP Pin Control 0 Register (RTPPC0) (offset = 34h)

37.3.13 RTP Pin Control 4 Register (RTPPC4)

This register provides the option to set pins to a logic 1 level without influencing the state of other pins. It eliminates the read-modify-write operation necessary with the RTPPC3 register. Once the pin is configured in functional mode (using RTPPC0 register), setting the corresponding bit to 1 in RTPPC4 will not affect the pin's state. Figure 37-21 and Table 37-22 describe this register.

Figure 37-21. RTP Pin Control 4 Register (RTPPC4) (offset = 44h)

Table 37-22. RTP Pin Control 4 Register (RTPPC4) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reads return 0. Writes have no effect.
18	ENASET		Sets the output state of $\overline{\text{RTPENA}}$ pin to logic high. Value in the ENASET bit sets the data output control register bit to 1 regardless of the current value in the ENAOUT bit .
			Read:
		0	The pin is configured to output a logic low (0) (output voltage is V_{OL} or lower).
		1	The pin is configured to output logic high (1) (output voltage is V_{OH} or higher).
			Write:
		0	No effect.
		1	Set pin to logic high (1) (output voltage is V_{OH} or higher).
17	CLKSET		Sets the output state of RTPCLK pin to logic high. Value in the CLKSET bit sets the data output control register bit to 1 regardless of the current value in the CLKOUT bit.
			Read:
		0	The pin is configured to output a logic low (0) (output voltage is V_{OL} or lower).
		1	The pin is configured to output logic high (1) (output voltage is V_{OH} or higher).
			Write:
		0	No effect.
		1	Set pin to logic high (1) (output voltage is V_{OH} or higher).
16	SYNCSET		Sets output state of RTPSYNC pin logic high. Value in the SYNCSET bit sets the data output control register bit to 1 regardless of the current value in the SYNCOUT bit.
			Read:
		0	The pin is configured to output a logic low (0) (output voltage is V_{OL} or lower).
		1	The pin is configured to output logic high (1) (output voltage is V_{OH} or higher).
			Write:
		0	No effect.
		1	Set pin to logic high (1) (output voltage is V_{OH} or higher).
15-0	DATASET[*n*]		Sets output state of RTPDATA[15:0] pins to logic high. Value in the DATAxSET bit sets the data output control register bit to 1 regardless of the current value in the DATAxOUT bit. Each bit [*n*] represents a single pin.
			Read:
		0	The pin is configured to output a logic low (0) (output voltage is V_{OL} or lower).
		1	The pin is configured to output logic high (1) (output voltage is V_{OH} or higher).
			Write:
		0	No effect.
		1	Set pin to logic high (1) (output voltage is V_{OH} or higher).

37.3.15 RTP Pin Control 6 Register (RTPPC6)

This register configures the pins in push-pull or open-drain functionality. If configured to be open-drain, the module only drives a logic low level on the pin. An external pull-up resistor needs to be connected to the pin to pull it high when the pin is in high-impedance mode. Figure 37-23 and Table 37-24 describe this register.

Figure 37-23. RTP Pin Control 6 Register (RTPPC6) (offset = 4Ch)

37.3.16 RTP Pin Control 7 Register (RTPPC7)

This register controls the pullup/down functionality of a pin. The internal pullup/down can be enabled or disabled by this register. The reset configuration of these bits is device dependent, consult the device datasheet for this information. Figure 37-24 and Table 37-25 describe this register.

Figure 37-24. RTP Pin Control 7 Register (RTPPC7) (offset = 50h)

37.3.17 RTP Pin Control 8 Register (RTPPC8)

This register configures the internal pullup or pulldown on the input pin. A secondary function exists when the pull configuration is disabled and a pulldown is selected. This will disable the input buffer. Figure 37-25 and Table 37-26 describe this register.

NOTE: If the pullup/down is disabled in the RTPPC7 register and configured as pulldown in RTPPC8, then the input buffer is disabled.

eFuse Controller

This chapter describes the eFuse controller.

Topic **Page**

38.1 Overview **2188**
38.2 Introduction **2188**
38.3 eFuse Controller Testing **2188**
38.4 eFuse Controller Registers **2191**

Copyright © 2018, Texas Instruments Incorporated

38.1 Overview

Electrically programmable fuses (eFuses) are used to configure the device after deassertion of $\overline{\text{PORRST}}$. The eFuse values are read and loaded into internal registers as part of the power-on-reset sequence. The eFuse values are protected with single bit error correction, double bit error detection (SECDED) codes. These fuses are programmed during the initial factory test of the device. The eFuse controller is designed so that the state of the eFuses cannot be changed once the device is packaged.

38.2 Introduction

The eFuse controller automatically reads the values of the eFuses and shifts them into registers during the power-on reset sequence. No action is required from the application code. However, in a safety critical application, the user code should check to see if a correctable or an uncorrectable error was detected during the reset sequence and then preform a self-test on the eFuse controller ECC logic.

38.3 eFuse Controller Testing

38.3.1 eFuse Controller Connections to ESM

There are three connections from the eFuse controller to the Error Signaling Module (ESM). If an uncorrectable error occurs during the loading of the eFuse values after reset, a group three, channel one error and a group one channel 40 error are sent to the ESM. The group three error will cause the $\overline{\text{ERROR}}$ pin to go low. If during the eFuse loading a correctable error occurs, only a group one channel 40 error is sent to the ESM. If an error occurs during the eFuse controller self test, then a group one channel 41 error and a group one channel 40 error are sent to the ESM. After reset, by default, the group one errors do not affect the $\overline{\text{ERROR}}$ pin. If the software enables the appropriate bit in the appropriate ESM Influence Error Pin Set/Status Register (ESMIEPSRn) while the group one error is set, the $\overline{\text{ERROR}}$ pin will go low.

Table 38-1. ESM Signals Set by eFuse Controller

ESM Signal	Uncorrected Load Failure	Correctable Load Error	Self Test		
			eFuse Self Test	eFuse stuck at 0 Test	
				Version a: with Error pin	Version b: without Error pin
Group 3 Channel 1	X			X	
Group 1 Channel 40	X	X	X		
Group 1 Channel 41			X	X	X

38.3.2 Checking for eFuse Errors After Power Up

For safety critical systems, it is required that you check the status of the eFuse controller after a device reset. A suggested flow chart for checking the eFuse controller after device reset is shown in Figure 38-1. Failures during the eFuse self test can be grouped into three levels of severity. Depending on the safety critical application, the error handling for each error type may be different.

38.3.2.1 Class 1 Error

A class 1 error of the eFuse controller means that there was a failure during the autoload sequence. The values read from the eFuses cannot be relied on. All device operation is suspect. A class 1 error is indicated by a signal to group 3 channel 1 of the ESM. This will cause the $\overline{\text{ERROR}}$ pin to go active low.

38.3.2.2 Class 2 Errors

A class 2 error is an indication that the safety checks of the eFuse controller did not work. These are also serious errors because you can no longer guarantee that a more severe error did not occur.

Copyright © 2018, Texas Instruments Incorporated

38.3.2.3 Class 3 Error

A class 3 error indicates that there was a single bit failure reading the eFuses that was corrected by ECC bits. Proper operation is still likely, but the system is now at a higher risk for a future non-correctable error. When a correctable error occurs, ESM group 1, channel 40 will be set. In the suggested flow chart shown in Figure 38-1 below, the single bit error is determined by directly reading the eFuse error status register, and not depending on the integrity of the connections between the eFuse controller and the ESM.

38.3.2.4 Stuck at Zero Test

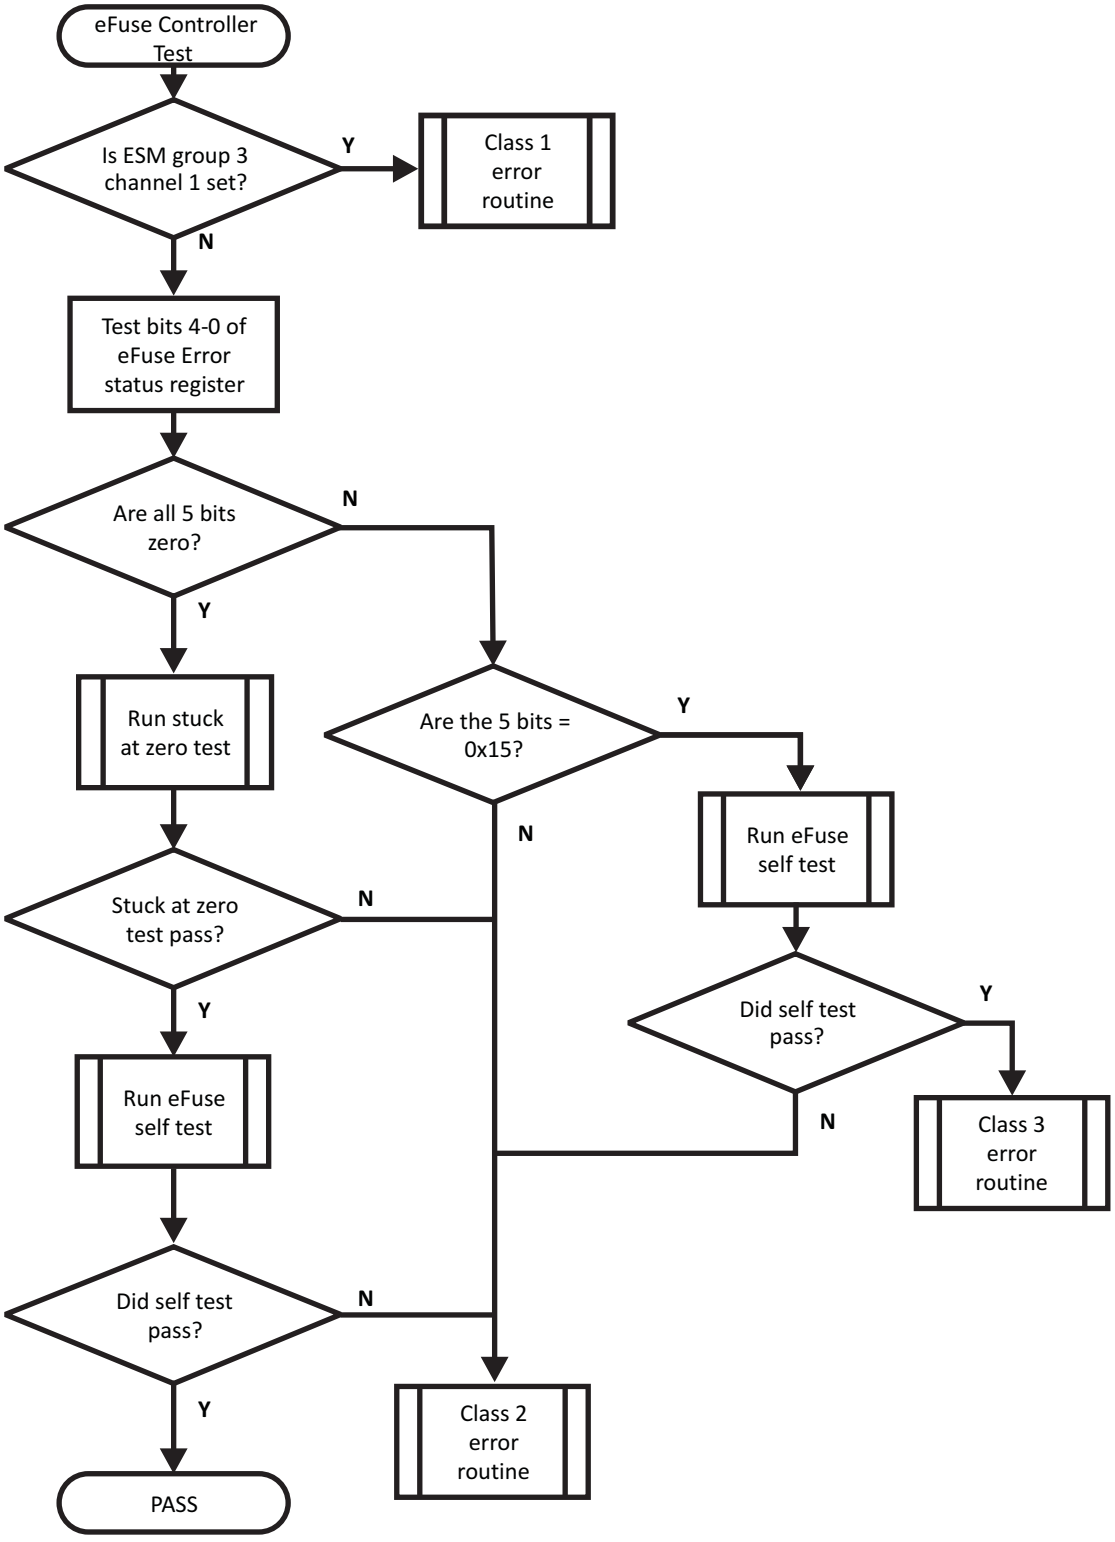
The purpose of the stuck at zero test is to verify that the eFuse controller could signal the ESM if an autoload error did occur. It basically verifies the path through the eFuse controller and to the ESM. This is done by writing a special instruction to the eFuse controller boundary register, then verifying that the proper bits are set in the eFuse controller pins register. Upon successful completion of this test ESM group 1 channel 41 and ESM group 3 channel 1 will be set. This will force the $\overline{\text{ERROR}}$ pin low.

- Version A
  - Write boundary register (address 0xFFF8C01C) with 0x003FC000 to set the error signals.
  - Read pins register (address 0xFFF8C02C) and verify that bits 14, 12, 11 and 10 are set.
  - Write boundary register (address 0xFFF8C01C) with 0x003C0000, to clear the error signals.
  - Verify that ESM group 1 channel 41 and group 3 channel 1 are set, then clear them.

If the system cannot support a test which causes the ERROR pin to go low, then the stuck at zero test can be modified as follows:

- Version B
  - Write boundary register (address 0xFFF8C01C) with 0x003BC000.
  - Read pins register (address 0xFFF8C02C) and verify that bits 14, 12, and 11 are set.
  - Write boundary register (address 0xFFF8C01C) with 0x003C0000, to clear the error signals.
  - Verify that ESM group 1 channel 41 is set, then clear it.

This alternate method provides less test coverage because the path from the uncorrectable error signal from the eFuse controller to the ESM is not specifically tested. However, even if this path is broken, reading the five eFuse error status bits will indicate that an error occurred.



38.3.2.5 eFuse ECC Logic Self Test

The eFuse controller self test performs extensive validation of the ECC logic in the eFuse controller. This test should only be performed once for every device $\overline{\text{PORRST}}$ cycle. Perform the self test by following these steps:

- Write 0x00000258 to the self test cycles register (EFCSTCY) at address 0xFFF8C048.
- Write 0x5362F97F to the self test signature register (EFCSTSIG) at address 0xFFF8C04C.
- Write 0x0000200F to the boundary register at address 0xFFF8C01C. This triggers the self test. The test takes 610 VCLK cycles to complete. The application can poll bit 15 of the pins register at address 0xFFF8C02C to wait for the test to complete.
- Check ESM group 1 channels 40 and 41 for any errors, neither should be set.
- Verify that bits 4 to 0 of the eFuse Error Status register at address 0xFFF8C03C are zero.

38.4 eFuse Controller Registers

All registers in the eFuse Controller module are 32-bit, word-aligned; 8-bit, 16-bit and 32-bit accesses are allowed. Table 38-2 provides a quick reference to each of these registers. Specific bit descriptions are discussed in the following subsections. The base address for the control registers is FFF8 C000h.

Table 38-2. eFuse Controller Registers

Offset	Acronym	Register Description	Section
1Ch	EFCBOUND	EFC Boundary Control Register	Section 38.4.1
2Ch	EFCPINS	EFC Pins Register	Section 38.4.2

Table 38-3. EFC Boundary Register (EFCBOUND) Field Descriptions (continued)

Bit	Field	Value	Description
19	EFC Instruction Error		This bit drives the instruction error signal when bit 15 (Instruction Error OE) is high. This signal is used to denote an error occurred during e-fuse programming. This signal is not attached to the ESM.
		0	Drives the Instruction Error signal low, if Instruction Error OE is high.
		1	Drives the Instruction Error signal high, if Instruction Error OE is high.
18	EFC Autoload Error		This bit drives the Autoload Error signal when bit 14 (Autoload Error OE) is high. This signal is attached to ESM error Group 3, Channel 1.
		0	Drives the Autoload Error signal low, if Autoload Error OE is high.
		1	Drives the Autoload Error signal high, if Autoload Error OE is high.
17	Self Test Error OE		The Self Test Error Output Enable bit determines if the EFC Self Test signal comes from the eFuse controller or from bit 21 of the boundary register.
		0	EFC Self Test Error comes from eFuse controller.
		1	EFC Self Test Error comes from the boundary register.
16	Single Bit Error OE		The single bit error output enable signal determines if the EFC Single Bit Error signal comes from the eFuse controller or from bit 20 of the boundary register.
		0	EFC Single Bit Error comes from eFuse controller.
		1	EFC Single Bit Error comes from the boundary register.
15	Instruction Error OE		The instruction error output enable signal determines if the EFC Instruction Error signal comes from the eFuse controller or from bit 19 of the boundary register.
		0	EFC Instruction Error comes from eFuse controller.
		1	EFC Instruction Error comes from the boundary register.
14	Autoload Error OE		The autoload error output enable signal determines if the EFC Autoload Error signal comes from the eFuse controller or from bit 18 of the boundary register.
		0	EFC Autoload Error comes from eFuse controller.
		1	EFC Autoload Error comes from the boundary register.
13	EFC ECC Selftest Enable		The eFuse Controller ECC Selftest Enable bit starts the selftest of the ECC logic if the four input enable bits (EFCBOUND[3:0) are all 1s.
		0	No action
		1	Start ECC selftest if EFCBOUND[3:0] are Fh.
12-4	Reserved	0	Read returns 0. Writes have no effect.
3-0	Input Enable		The eFuse Controller ECC Selftest Enable bit starts the selftest of the ECC logic if the four input enable bits (EFCBOUND[3:0) are all 1s.
		Fh	ECC selftest can be started if EFC ECC Selftest Enable, bit 13, is set
		All others	ECC selftest cannot be started.

Table 38-4. EFC Pins Register (EFCPINS) Field Descriptions

Bit	Name	Value	Description
31–16	Reserved	0	Reads return zeros, writes have no effect.
15	EFC Selftest Done		This bit can be polled to determine when the EFC ECC selftest is complete
		0	EFC ECC selftest is not complete.
		1	EFC ECC selftest is complete.
14	EFC Selftest Error		This bit indicates the pass/fail status of the EFC ECC Selftest once the EFC Selftest Done bit (bit 15) is set.
		0	EFC ECC Selftest passed.
		1	EFC ECC Selftest failed.
13	Reserved	0	Reads return zeros. Do NOT write a 1 to this bit.
12	EFC Single Bit Error		This bit indicates if a single bit error was corrected by the ECC logic during the autoload after reset.
		0	No single bit error was detected.
		1	A single bit error was detected and corrected.
11	EFC Instruction Error		This bit indicates an error occurred during a factory test or program operation. This bit should not be set from normal use.
		0	No instruction error detected.
		1	An error occurred during a factory test or program operation.
10	EFC Autoload Error		This bit indicates that some non-correctable error occurred during the autoload sequence after reset. This bit also sets ESM group 3, channel 1.
		0	The autoload function completed successfully.
		1	There were non-correctable errors during the autoload sequence.
9-0	Reserved	0-1	After reset, these bits are indeterminate and reads return either a 1 or 0.

- Figure 20-108: Updated Read/Write value of TERE bit to R/W1CP-0 786
- Table 20-99: Updated Value column of TER_OFF bit. Added 21h-3Fh = Reserved 787
- Table 20-103: Changed Description of TTYPE bit. (A request triggers) 790
- **Chapter 21: External Memory Interface (EMIF)** 793
- Figure 21-1: Corrected pin names 795
- Figure 21-1: Deleted EMIF_RNW pin 795
- Table 21-3: Deleted EMIF_RNW pin 797
- Figure 21-18: Updated reset value of RR bit to 80h 831
- Figure 21-24: Changed bit 1 to LT_MASK_SET 837
- Figure 21-25: Changed bit 1 to LT_MASK_CLR 838
- Figure 21-27: Corrected pin names 841
- **Chapter 22: Analog To Digital Converter (ADC) Module** 848
- Figure 22-1: Corrected EXT_SEL and EXT_ENA signals 850
- Figure 22-2: Corrected Event Trigger Generation signal 851
- Figure 22-2: Corrected EXT_SEL and EXT_ENA signals 851
- Figure 22-2: Deleted EXT_nENA signal 851
- Section 22.1.1.3: Updated third and fifth sentences in third paragraph 852
- Section 22.2.1.3: Added last sentence (reference) to fourth paragraph 854
- Figure 22-10: Corrected bit range of the EV_CURRENT_COUNT, EV_MAX_COUNT, G1_CURRENT_COUNT, G1_MAX_COUNT, G2_CURRENT_COUNT, and G2_MAX_COUNT bits to 4-0 860
- Section 22.2.5.3: Corrected register names in first sentence. (ADMAGINTENASET and ADMAGINTENACLR) 870
- Table 22-11: Changed Description of FRZ_EV bit. (The Event Group conversion is kept frozen while the Group1 or Group2 conversion is active,) 888
- Table 22-12: Changed Description of FRZ_G1 bit. (The Group1 conversion is kept frozen while the Event Group or Group2 conversion is active,) 891
- Table 22-13: Changed Description of FRZ_G2 bit. (The Group2 conversion is kept frozen while the Event Group or Group1 conversion is active,) 894
- Table 22-28: Changed Description for DMA_G2_END bit. Corrected group number to 2 911
- Figure 22-53: Deleted Reserved bits. Changed EV_SEL bits to 31-0 920
- Table 22-37: Deleted Reserved bits. Changed EV_SEL bits to 31-0 920
- Figure 22-54: Deleted Reserved bits. Changed G1_SEL bits to 31-0 921
- Table 22-38: Deleted Reserved bits. Changed G1_SEL bits to 31-0 921
- Figure 22-55: Deleted Reserved bits. Changed G2_SEL bits to 31-0 922
- Table 22-39: Deleted Reserved bits. Changed G2_SEL bits to 31-0 922
- Table 22-42: Changed Description of LAST_CONV bit for Value = 1. (A level higher than or equal to the midpoint reference voltage) 924
- **Chapter 23: High-End Timer (N2HET) Module** 953
- Section 23.2.5.4: Changed first sentence 973
- Table 23-9: Changed Pull Control and Input Buffer = Enabled when device is under reset 985
- Section 23.2.9: Updated first paragraph 990
- Section 23.3.2: Added Hardware Angle Generator (HWAG) subsection. Subsequent figures and tables renumbered 995
- Figure 23-56: Changed format 1018
- Table 23-16: Updated Description of PPF and TO bits 1018
- Table 23-17: Updated Description of LRPFC and HRPFC bits 1020
- Table 23-26: Changed Description of HETPRY bit 1026
- Section 23.5: Added HWAG Registers section. Subsequent section, figures, and tables renumbered 1044
- Table 23-73: Added cross references to instruction descriptions 1060
- Table 23-73: Added OR instruction 1060
- Table 23-73: Corrected sub-opcodes for ADC, ADD, and XOR instructions 1060
- Table 23-74: Added SUB to Set/Reset column for Zero flag (Z) 1061
- Section 23.6.3.8: Updated Description of CNT instruction. The data field [D31:7] is incremented unconditionally on each execution of the instruction 1086
- Table 23-87: Changed registers in Source and Destination(s) columns to register A, B, R, S, or T 1103
- Section 23.6.3.19: Updated Description of RCNT instruction. For example, choosing M = 100 allows the input period to be

IMPORTANT NOTICE FOR TI DESIGN INFORMATION AND RESOURCES

Texas Instruments Incorporated ('TI") technical, application or other design advice, services or information, including, but not limited to, reference designs and materials relating to evaluation modules, (collectively, "TI Resources") are intended to assist designers who are developing applications that incorporate TI products; by downloading, accessing or using any particular TI Resource in any way, you (individually or, if you are acting on behalf of a company, your company) agree to use it solely for this purpose and subject to the terms of this Notice.

TI's provision of TI Resources does not expand or otherwise alter TI's applicable published warranties or warranty disclaimers for TI products, and no additional obligations or liabilities arise from TI providing such TI Resources. TI reserves the right to make corrections, enhancements, improvements and other changes to its TI Resources.

You understand and agree that you remain responsible for using your independent analysis, evaluation and judgment in designing your applications and that you have full and exclusive responsibility to assure the safety of your applications and compliance of your applications (and of all TI products used in or for your applications) with all applicable regulations, laws and other applicable requirements. You represent that, with respect to your applications, you have all the necessary expertise to create and implement safeguards that (1) anticipate dangerous consequences of failures, (2) monitor failures and their consequences, and (3) lessen the likelihood of failures that might cause harm and take appropriate actions. You agree that prior to using or distributing any applications that include TI products, you will thoroughly test such applications and the functionality of such TI products as used in such applications. TI has not conducted any testing other than that specifically described in the published documentation for a particular TI Resource.

You are authorized to use, copy and modify any individual TI Resource only in connection with the development of applications that include the TI product(s) identified in such TI Resource. NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER TI INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT OF TI OR ANY THIRD PARTY IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information regarding or referencing third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of TI Resources may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI RESOURCES ARE PROVIDED "AS IS" AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING TI RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY YOU AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

You agree to fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of your non-compliance with the terms and provisions of this Notice.

This Notice applies to TI Resources. Additional terms apply to the use and purchase of certain types of materials, TI products and services. These include; without limitation, TI's standard terms for semiconductor products http://www.ti.com/sc/docs/stdterms.htm), evaluation modules, and samples (http://www.ti.com/sc/docs/sampterms.htm).
