

TI Designs: TIDEP-0099

采用 C6747 且适用于基于语音的应用的音频 预处理 系统参考设计

说明

TIDEP-0099 采用多个麦克风（八个），借助波束形成算法和其他算法，可从包含噪声源的环境中清理噪声，并提取清晰的语音。随着语音激活应用 的迅速发展，越来越多的用户有意获取能够从嘈杂环境中提取清晰语音的系统。这些系统在具有语音触发和语音识别功能的应用 中尤为重要。本设计指南介绍了如何使用圆形麦克风板 (CMB)、OMAP-L137/TMS320C6747 浮点入门套件 (SK) 在 C6747 器件上运行演示，还讨论了用于过滤音频噪声的各种概念。

特性

- 使用单个数字信号处理器 (DSP) 和麦克风阵列从嘈杂的环境中提取清晰语音
- 从音频源中消除背景噪声和杂波
- 通过向识别引擎呈现清晰的语音音频来实现更好的语音识别
- 使用 TI 提供的软件、评估模块和麦克风阵列提供完整的系统参考设计

应用

- 用于语音激活数字助理应用的基于云接口的语音 识别
- 用于智能家居应用的基于云接口的语音 识别
- 用于基于语音的电器控制的本地（有限字典）语音识别
- 语音 应用（如视频会议）

该 TI 参考设计末尾的重要声明表述了授权使用、知识产权问题和其他重要的免责声明和信息。

1 System Description

The TIDEP-0099 uses TI hardware and sophisticated, field-proven software algorithms to obtain clear speech and audio from noisy environments. The ability to extract clear speech or audio from a noisy environment is important to many applications that use voice-activation, such as digital assistants, telephone and video conferencing, and other high-quality speech systems. Typical sources of sound clutter are undesired background noise sources and so forth. This TI Design uses a beamforming algorithm to form a virtual-directional microphone that points at the direction of the speaker or the desired audio source. This amplifies the speech signal from the desired direction, and attenuates signals from all other directions. In addition to beamforming, TI offers a set of audio algorithms that further improves the quality of sound. 2.3 节 summarizes the theory of the beamforming, which uses multiple microphones, an associated adaptive spectral noise reduction (ASNR) filter, and the multiple source selection (MSS) algorithm to obtain the virtual-directional microphone signal.

The interface between the microphone array and the processor must support streaming of multiple data inputs. The data rate depends on the application requirements. The TIDEP-0099 streams eight microphones mounted on circular microphone board (CMB), samples in 16-bits at 16000 samples per second, and uses the analog-to-digital converter (ADC) PCM1864 for an inter-IC sound (I2S) interface to the evaluation module (EVM) board. The PCM1864 is a highly flexible audio front end supporting input levels from small-mV microphone inputs to 2.1 VRMS line inputs without external resistor dividers. This device is highly configurable and able to support both analog and digital microphones.

The EVM supports multiple audio output avenues. The audio data can be processed locally or sent out through one of the OMAP-L137/TMS320C6747 Floating Point SK external ports.

An application that uses local processing, such as voice-recognition remote-control appliances, can process the data locally. The TIDEP-0099 loops the clean audio back into the left channel of the stereo audio output interface from the onboard AIC3204 audio codec. The reference microphone (one of the microphones in the circular microphone array) plays out of the right channel. This setup enables the user to compare the quality of processed and unprocessed audio.

This TI Design includes full source code that can be modified to support various applications. For an optional cloud-based, voice-activated digital assistant design, the output signal can be sent to a network interface device using external interface, such as UART, SPI, or USB. The return audio signal from the network can be sent to the device codec to be played by a speaker. Local (limited dictionary) voice recognition for voice-activated digital assistant applications could use the DSP to do voice recognition. The DSP in the C6747 is a high-performance, floating-point VLIW DSP core clocked at 456 MHz. The DSP has enough power and memory to support voice recognition of a limited dictionary. Conference call and other speech-processing applications require additional features (mixing of signals, acoustic echo cancellation, and so on). As stated above, the DSP in the EVM has enough power and memory to process limited speech algorithms. Note that TI audio libraries include optimized audio algorithms that can be used by speech applications.

2 System Overview

2.1 Block Diagram

图 2. Block Diagram

2.2 Highlighted Products

2.2.1 TMS320C6747

The TMS320C6745/6747 device is a low-power digital signal processor based on a TMS320C674x DSP core. The device consumes significantly lower power than other members of the TMS320C6000 platform of DSPs.

The TMS320C6745/6747 DSP core uses a two-level cache-based architecture. The Level 1 program cache (L1P) is a 32-KB direct mapped cache and the Level 1 data cache (L1D) is a 32-KB 2-way set-associative cache. The Level 2 program cache (L2P) consists of a 256-KB memory space that is shared between program and data space. L2 memory can be configured as mapped memory, cache, or combinations of the two.

图 3 highlights the set of peripherals available on the C6747.

图 3. Overview of C6747 SoC

- Software support
 - Processor SDK for C6747
- DSP
 - 456-MHz C6747 VLIW DSP
- C6747 instruction set features

- Superset of the C67x+ and C64x+ ISAs
- Up to 3648 MIPS and 2736 MFLOPS C674x
- Byte-addressable (8-, 16-, 32-, and 64-Bit Data)
- C674x two-level cache memory architecture
 - 32KB of L1P program RAM/Cache
 - 32KB of L1D data RAM/Cache
 - 256KB of L2 unified mapped RAM/Cache
 - Flexible RAM/Cache partition (L1 and L2)
- Enhanced direct memory access controller 3 (EDMA3):
 - Two transfer controllers
 - 32 independent DMA channels
 - Eight quick DMA channels
 - Programmable transfer burst size
- 128KB of RAM shared memory
- 3.3-V LVCMOS I/Os (except for USB interfaces)
- Two external memory interfaces
- Three configurable 16550-type UART modules
- LCD controller
- Two serial peripheral interfaces (SPIs) each with one chip select
- Multimedia card (MMC) and secure digital (SD) card interface with secure data I/O (SDIO)
- Two master and slave inter-integrated circuit (I2C Bus)
- One host-port interface (HPI) with 16-bit-wide muxed address and data bus for high bandwidth
- Programmable real-time unit subsystem (PRUSS)
- USB 1.1 OHCI (host) with integrated PHY (USB1)
- USB 2.0 OTG port with integrated PHY (USB0)
- Three multichannel audio serial ports (McASPs):
 - Six clock zones and 28 serial data pins
 - Supports TDM, I2S, and similar formats
 - DIT-capable (McASP2)
 - FIFO buffers for transmit and receive
- 10/100 Mbps Ethernet MAC (EMAC):
 - IEEE 802.3 compliant (3.3-V I/O Only)
 - RMI media-independent interface
 - Management Data I/O (MDIO) module
- Real-time clock with 32-kHz oscillator and separate power rail
- One 64-bit general-purpose timer (configurable as two 32-bit timers)
- One 64-bit general-purpose watchdog timer (configurable as two 32-bit general-purpose timers)
- 256-ball Pb-free plastic ball grid array (PBGA) [ZKB Suffix], 1.0-mm Ball Pitch

- Commercial, industrial, extended, or automotive temperature

2.2.2 PCM1864

The PCM1864 is a 103-dB, two stereo channel (four channels total), SW-controlled audio ADC with universal front end.

See ti.com's [PCM1864](#) product folder for a full description of this device.

2.2.3 CMB

Seven microphones are mounted at equal arc distances from each other on a circle. The eighth microphone is mounted at the center of the circle. The PCM1864 samples the eight microphones and streams the digital values using McASP interfaces to the OMAP-L137/TMS320C6747 Floating Point SK audio expansion (AE) connection on the EVM. Schematics of the CMB are available in [4.1 节](#).

This board is available from ti.com; see *Processor SDK RTOS Audio Pre-Processing* [\[1\]](#) for more information.

2.2.4 OMAP-L137/TMS320C6747 Floating Point SK

The OMAP-L137/TMS320C6747 Floating Point SK is an evaluation module based on the OMAP-L137 processor. For a full description of the SK, see ti.com's [OMAP-L137/TMS320C6747 Floating Point SK](#) tools folder.

图 4 shows a block diagram of the OMAP-L137/TMS320C6747 Floating Point SK.

图 4. OMAP-L137/TMS320C6747 Floating Point SK Block Diagram

2.2.5 PROCESSOR-SDK-RTOS-OMAP-L137

Processor SDK is a unified software platform for TI embedded processors, which provides easy setup and fast out-of-the-box access to benchmarks and demonstrations. All releases of Processor SDK are consistent across TI's broad portfolio, which allows developers to seamlessly reuse and migrate software across devices. The Processor SDK consists of two types: LINUX and RTOS. The LINUX release (PROCESSOR-SDK-LINUX-OMAPL137) contains LINUX tools, drivers, and utilities for ARM processors. The RTOS (PROCESSOR-SDK-RTOS-OMAPL137) release contains RTOS, drivers, utilities, tools, high-level drivers, and optimized library as well as examples and demonstration projects. The TIDEP-0099 requires the Processor SDK RTOS.

Free download of PROCESSOR-SDK-RTOS-OMAPL137 is available at ti.com's [Processor SDK OMAPL137](#) tools folder.

2.2.5.1 OMAPL137_bf_rt Project

The OMAPL137_bf_rt project is part of the Processor SDK RTOS package. The project contains code that processes seven streams of audio from the CMB, and applies beamforming, ASNR, and MSS to obtain a single, virtual-directional microphone directed at speech, and cleans up noise from the environment. The processed audio is linked to the left channel of the stereo audio output interface using the OMAP-L137/TMS320C6747 Floating Point SK onboard audio codec. The microphone that is mounted at the center of the CMB is used as a reference microphone. The audio from the reference microphone is linked to the right channel of the stereo audio output interface using the OMAP-L137/TMS320C6747 Floating Point SK onboard audio codec. This feature enables the user to compare the original audio with the processed audio. This project uses the same CMB library that is mentioned in [节 2.2.5.2](#).

注： OMAPL137_bf_rt is the main project in this TI Design. The other two projects are for hardware debugging of the CMB board (audioAnalogLoopbackTest Project) and for illustrating the quality improvements of using beamforming and the other algorithms (DA830_bf Project).

2.2.5.2 audioAnalogLoopbackTest Project

The CMB project (C:\ti\pdk_omap137_xx_xx_xx\packages\ti\addon\cmb) is part of the Processor SDK RTOS package and may be used to debug the CMB board.

The project contains code to receive eight microphone streams from the CMB. The first of the eight microphones is linked to the left channel of the stereo audio output interface using the OMAP-L137/TMS320C6747 Floating Point SK onboard audio codec. Note that the user may choose any one of the eight microphones to link to the left channel of the stereo audio output interface and rebuild the project. The microphone that is at the center of the CMB is linked to the right channel of the stereo audio output interface, which uses the SK onboard audio codec. All streams from the other seven microphones of the CMB are ignored. The user can choose any one of the eight microphones to connect to the onboard codec. If the user manipulates the desired microphone channeled to the onboard audio codec, the project must be rebuilt.

The project uses the CMB library (ti.addon.cmb.ae66 for little endian and ti.addon.cmb.ae66e for big endian). The CMB library contains sets of utilities and drivers to control audio interfaces on the CMB and to facilitate audio streaming IO to and from the OMAP-L137/TMS320C6747 Floating Point SK.

2.2.5.3 DA830_bf Project

The DA830_bf project (C:\ti\processor_sdk_rtos_omap137_xx_xx_xx_xx\demos\audio-preprocessing\file_demo_bios\omap137) is part of the Processor SDK RTOS package and may be used to illustrate the quality improvements of using beamforming and the other algorithms. The project contains code that reads prerecorded audio files from the array of microphones, performs multidirectional beamforming, ASNR, and uses MSS to choose the best directional virtual microphone and store the microphone output in a file. This project can be used to illustrate the quality of beamforming and for debugging and demonstration. This code requires multiple simulated or recorded microphone audio data that can be purchased from third party (for example, from Harman Kardon™). The filter coefficients for the beamforming should be generated by the user. The AER package contains a tool that generates filter coefficients based on the geometry of the microphones. 节 3.2.1.5 describes how to generate filter coefficients.

2.2.5.4 Source Code and Makefiles

In addition to the three executables that are mentioned in 节 2.2.5.1, 节 2.2.5.2, and 节 2.2.5.3, the Processor SDK RTOS contains full source code and a set of makefiles. The source code can be used as a starting point for user applications. In addition, TI provides a set of makefiles to build the projects. The location of the audioAnalogLoopbackTest project is in PDK\ti\addon\cmb\test folder where PDK is the directory where Process SDK RTOS Platform or Processor Development Kit (PDK) is installed. The OMAPL137_bf_rt and the DA830_bf_bios projects are located in the Processor SDK under the demos folder.

2.2.6 TI Audio Libraries

TI Audio Libraries (TELECOMLIB) consists of two optimized libraries that are used in this reference design: the Acoustic Echo Cancellation-Removal (AEC-AER) library and the Voice Library (VOLIB). In addition, the Processor SDK includes a set of optimized libraries that can be used, such as DSPLIB, that contains many signal processing optimized algorithms. AEC-AER and VOLIB can be downloaded from ti.com's [TELECOM](#) tools folder.

注: The user must install AEC-AER and VOLIB libraries as subdirectories of the Processor SDK. That is, the same root location that PDK is installed.

2.3 System Design Theory

2.3.1 Beamforming

The ability to extract clear speech or audio from a noisy environment is important to many applications that use voice-activated techniques, such as telephone and video conferencing and other high-quality speech systems. Typical sources of sound-clutter are undesired background noise sources, reverberation, and acoustic echo. The TIDEP-0099 uses a beamforming algorithm to form a virtual-directional microphone that points to the direction of the speaker or the desired audio source. The beamforming algorithm amplifies the speech signal from the desired direction and attenuates all signals from all other directions. In addition to beamforming, TI offers a set of audio algorithms that may further improve the quality of sound-like dynamic range compression. An overview of the audio beamforming mathematics and algorithm can be found in *Acoustic Source Localization and Beamforming: Theory and Practice* [8]

and *Beamforming* [9] on Wikipedia. A group of microphones are mounted in predefined locations, which are either along a straight line or on a circle. A point sound source reaches different microphones with different phase delay. The phase delay depends on the frequency, the speed of sound, the distance between each microphone, and the sound source. The distances between the source and the microphones are function of the direction.

图 5 shows the distance and the phase difference between two microphones as a function of the direction of the signal arrival.

图 5. Differences in Distance, Time, and Phase Between Two Microphones

From 图 5, d_1 is calculated in 公式 1.

$$d_1 = d_0 \times \cos(\alpha) \quad (1)$$

The signal time difference, Δ_t , between mic1 and mic2 is d_1 divided by the speed of sound, as shown in 公式 2.

$$\Delta_t = \frac{d_1}{\text{sos}} \quad (2)$$

The phase difference between mic1 and mic2 is shown in 公式 3.

$$\Delta_\theta = 2 \times \pi \times \Delta_t \times f = 2 \times \pi \times f \times \frac{d_1}{\text{sos}} = 2 \times \pi \times f \times d_0 \times \frac{\cos(\alpha)}{\text{sos}} \quad (3)$$

Where:

- Δ_θ is the phase difference
- f is the signal frequency
- d_0 is the distance between two microphones
- α is the angle of arrival and sos is the speed of sound

In a multi-microphone beamforming system, the algorithm applies a set of delay filters to the microphones' signals to shift the signal phase and get the same phase for all the signals (from all microphones) that arrive from one direction. The contribution of all filtered microphones signals are summed together. Thus, the process amplifies signals that arrive from that direction. Because the phase shift (see 公式 3) depends on the angle of arrival (AOA), the phases of filtered signals that arrive from other directions are not the same. Therefore, the sum of all the signals from another direction is decreased, and the energy of the noise (undesired signal that comes from another direction) is reduced.

From 公式 3, it is clear that the quality of the reduction of noise depends on the noise frequency. While the beamforming filters are designed to reduce noise from typical mid-range and higher frequencies, low-frequency noise will not be reduced. An adaptive ASNR filter is applied to reduce the effect of low-frequency noise. 图 6 shows the reduction of noise as a function of frequency when the beamforming and the ASNR are applied.

图 6. ASNR and BF Noise Reduction as a Function of Noise Frequency

2.3.2 Multi-Angle Beamforming

图 7 shows typical multi-angle beamforming where multiple beamforming delay filters and ASNR filters are applied to the microphone sets' data. Each BF and ASNR output corresponds to a different AOA and behaves like a directional microphone; therefore, it is called virtual microphone. An MSS algorithm chooses the best fit virtual microphone.

3 Hardware, Software, Testing Requirements, and Test Results

3.1 Required Hardware and Software

TIDEP-0099 features a real-time BF demonstration, which runs on the OMAP-L137/TMS320C6747 Floating Point SK. This section will demonstrate how to setup the hardware and software in order to test this demonstration.

3.1.1 Hardware

Here is a list of hardware components needed to run the demonstration:

- OMAP-L137/TMS320C6747 Floating Point SK with power supply
- OMAP-L137 Prototyping Board
- Circular Microphone Board (CMB)
- Female-to-female jumper wires to connect the CMB to the headphones

3.1.1.1 OMAP-L137/TMS320C6747 Floating Point SK Hardware Setup

Detailed steps on how to setup the OMAP-L137/TMS320C6747 Floating Point SK are given in ti.com's tools folder.

图 4 shows the OMAP-L137/TMS320C6747 Floating Point SK layout and key components.

3.1.1.2 OMAP-L137 Prototyping Board

The OMAP-L137 prototyping board is an adapter board that gives access to various peripherals pins through headers.

- Over 7 in² of prototyping area
- Seven mounted expansion connectors
- Through hole breakout for expansion connectors
- Six power test points
- One 4-position user DIP switch and two 6-position user DIP switch for bus configuration
- Compatible with OMAP-L137 EVM and DA830 EVM
- Four power bars: GND, 5 V, 3.3 V, 1.8 V
- Size: 4.95 in × 3.35 in (125 mm × 110 mm)

图 8. OMAP-L137 Prototyping Board

表 2 lists the connections between the CMB and the OMAP-L137/TMS320C6747 Floating Point SK.

表 2. Connections Between CMB and OMAP-L137 Prototyping Board

图 10. OMAP-L137/TMS320C6747 Floating Point SK With CMB Connected

A stereo headset should be connected to the output audio. The audio connector line out is located at the bottom left of the OMAP-L137/TMS320C6747 Floating Point SK next to the audio expansion connector (see [图 11](#)).

图 11. Audio Extension and Audio Line Out on OMAP-L137/TMS320C6747 Floating Point SK

3.1.2 Software

The latest release of Processor SDK RTOS for OMAPL13x can be downloaded from ti.com's [PROCESSOR-SDK-RTOS-OMAPL137](#) tools folder.

See the Processor SDK RTOS Getting Started Guide[3] for information to start working with Processor SDK. For an advanced guide, see the *Processor SDK RTOS Software Developer Guide* [4]. The *Rebuilding The PDK* [5] wiki page has instructions to create all the PDK example projects.

This TI Design assumes that the user has PROCESSOR-SDK-RTOS-OMAPL13X installed and is familiar with the user guides.

This TI Design requires two audio libraries, as discussed in 节 2.2.6: AEC-AER and VOLIB library. The default C:\ti\ location can be used to install these dependent libraries. These libraries can be downloaded from ti.com's TELECOMLIB tools folder. Note that the C67x core uses VOLIB and AER library for C64Px.

3.2 Testing and Results

Testing of the beamforming system involves two steps. The first step is testing the complete audio path from the microphones to the OMAP-L137/TMS320C6747 Floating Point SK onboard codec. The second step is testing the beamforming processing quality. Objective testing is done by connecting the output audio signal to a PC and using an audio tool like Audacity® to compare two audio streams and to gauge their quality. Subjective testing is done by listening to the left and right channels streaming of the OMAP-L137/TMS320C6747 Floating Point SK onboard codec (headphone out) and comparing the quality. The following subsections detail how to build, run, and test the three projects.

图 12. Overview on Evaluating Audio Output of Voice Pre-processing Demonstration on OMAP-L137/TMS320C6747 Floating Point SK

图 13 describes the test environment.

图 13. Test Environment

3.2.1 Test Setup

3.2.1.1 Build and Run Executable

Three prebuilt executables are part of the TIDEP-0099 TI Design. The Processor SDK RTOS OMAPL13X contains the executables as well as all source code and makefiles to build the executable. This chapter contains instructions for building and running the three executables. The following instructions are for a Windows® computer. Instructions for LINUX® computer are given in the *Processor SDK RTOS Audio Pre-Processing* [1] wiki page.

The first step in building a project in Windows is to configure environment variables. The file *setupenv.bat* located in directory *C:\ti\processor_sdk_rtos_omap137_x_xx_xx_xx* is a batch file that sets the environment variables. This file is necessary to run in any new CMD window before starting a build (图 14). The user must configure the *SDK_INSTALL_PATH* and the *TOOLS_INSTALL_PATH* values based on the user directory structure unless Processor SDK and CCS were installed in the default location, which is *c:\ti*. *SDK_INSTALL_PATH* the location where Processor SDK was installed (*PROCESSOR_SDK_INSTALL_DIR*).

```

```

图 14. Setting up Build Environment by Running setenv.bat

Note that *SDK_INSTALL_PATH* directory has many subdirectories, which includes the PDK directory *pdk_omap137_1_0_1* (or a newer version). The *TOOLS_INSTALL_PATH* is the location where CCS was installed; this location has several subdirectories including *ccv6* (or newer). See the *Processor SDK RTOS Install In Custom Path* [6] wiki page. The CCS and SDK RTOS in Custom Path chapter in *Processor SDK RTOS Install in Custom Path* [6] provides details on how to set the environment variables.

Building the DA830_bf_bios project and the OMAPL137_bf_rt project with a custom path installation, requires configuring more environment variables.

The file setupenv.bat is in the top-level directory where *processor_sdk_rtos_omapl137_x_xx_xx_xx* was installed.

The user must configure SDK_INSTALL_PATH (line 52) to the upper directory where Processor SDK was installed. This directory contains the two audio libraries: AEC-AER and VOLIB. The user must configure TOOLS_INSTALL_PATH (line 57) to the upper directory where CCS was installed.

3.2.1.1.1 Build and Run OMAPL137_bf_rt Project

The OMAPL137_bf_rt project applies the beamforming algorithm and ASNR algorithms on seven microphones to generate eight virtual-directional microphones, which correspond to signal arrival angles of 0°, 45°, 90°, 135°, 180°, 225°, 270°, and 315°. The MSS algorithm chooses the virtual-directional signal with the most energy and channels its signal to the left channel headset through the audio codec on the OMAP-L137/TMS320C6747 Floating Point SK. The eighth microphone (the reference microphone in the center of the CMB) is channeled directly to the right headset channel as a reference.

The *Processor SDK RTOS Audio Pre-Processing* [1] wiki page details instructions to build and run the OMAPL137_bf_rt project.

1. After building the executable, the user should load this executable to the C674X DSP core as described in the wiki page and run the code.
2. The ideal method to evaluate the quality of audio processing is to have human speech tested in a noisy environment. Generate noise (white noise or music) from multiple locations in the room. Then, ask a person to speak or play an audio clip through PC speaker. At the same time, listen to the audio output via the stereo headset that is connected to the OMAP-L137/TMS320C6747 Floating Point SK onboard audio codec. In the stereo headset, the left side will output the processed audio (beamforming, ASNR, and MSS processing of the seven periphery microphones of the CMB), and the right side will play the reference unprocessed audio as is recorded by the microphone at the center of the CMB (microphone eight).
3. Objective testing is done by connecting audio signal to the line input connection of a PC and use an audio tool like Audacity to record and then compare two audio streams and to gauge their quality.

Chapter 6 of *Processor SDK RTOS Audio Pre-Processing* [1] shows how to read the input and output audio files and how to compare them. Subjective testing is done by listening to the left and right channels streaming of the OMAP-L137/TMS320C6747 Floating Point SK onboard codec and comparing the quality.

3.2.1.1.2 Build, Run, and Test audioAnalogLoopbackTest Project

The audioAnalogLoopbackTest.out is a stream through project where eight microphones from the CMB are streamed through the I2S connection from the CMB to the OMAP-L137/TMS320C6747 Floating Point SK. The project is described in 节 2.2.5.2.

The *Processor SDK RTOS CMB AddOn* [2] wiki page provides detailed instructions to build and run the audioAnalogLoopbackTest.

1. After building the executable, the user should load this executable to the C6747 DSP core using CCS as described in the wiki and run the code in a room with audio sources.
2. The OMAP-L137/TMS320C6747 Floating Point SK onboard audio codec left channel will stream one of the microphones (default microphone one), and the right side will stream a second microphone [default microphone eight (the one located in the center of the CMB)]. During objective testing, the output of the audio codec is connected to an audio utility on a PC that can show the audio signal and the characteristic of each side and verify that the two microphones and the path to the onboard codec is working correctly. Next two different microphones are connected, the project is rebuilt, and the experiment is repeated. Instructions how to change the microphones that are streaming audio are

given in 节 3.2.1.6.

3. An easy way to subjectively verify that all microphones are working properly is to connect the OMAP-L137/TMS320C6747 Floating Point SK onboard codec to a set of earphones and touch the microphones one after the other. The touching sound is heard only when the two connected microphones are touched. Next, change which microphones are connected to the audio codec and repeat the experiment.

3.2.1.1.3 Build and Run file_demo_bios (DA830_bf_bios) Project

The purpose of the DA830_bf_bios.out is to easily demonstrate the performances of the beamforming, ASNR, and MSS algorithm. The program plays seven prerecorded streams of raw audio data recorded from the seven microphones, processes the data, and generates output audio into a file. Each of the prerecorded files as well as the output audio file can be played on a speaker using a third-party audio tool, such as Audacity, to demonstrate the quality of the processing.

The prebuilt program assumes each of the seven microphones samples at 16000 times per second, each sample is embedded in 16-bit data, and each recording is 40 seconds or less; therefore, the size of each of the prerecorded files is limited to 1.28 MB (2 bytes per sample, 16000 samples per second, 40 seconds). The user must pre-load the seven files into the DSP memory prior to the execution.

Prerecorded raw data files can be obtained from a third party. Instructions on how to load these files manually or using a script file are given in Section 4.1.1.3.1. A set of synthetic audio files are part of the Processor SDK release in directory `C:\ti\processor_sdk_rtos_omap137_xx_xx_xx_xx\demos\audio-preprocessing\common\t8`.

The beamforming filters depend on the geometry of the microphone. Using prerecorded audio files requires a different set of filter coefficients. A set of filter coefficients that were built for the synthetic audio files are part of the Processor SDK release in directory `C:\ti\processor_sdk_rtos_omap137_xx_xx_xx_xx\demos\audio-preprocessing\common\filters`.

Detailed instructions how to build and run the DA830_bf_bios project is available in *Processor SDK RTOS Audio Pre-Processing* [1].

3.2.1.2 Loading Audio Files to Core Memory

The *Processor SDK RTOS Audio Pre-Processing* [1] wiki page describes how to load the prerecorded audio files that are part of the TI release. If the user wants to use different prerecorded audio files, the user must load the new audio files to the core memory by either using manual load, modifying the GEL file, or building a new GEL file.

3.2.1.2.1 Manual Load

The offline signal processing project dedicates eight 1.28-MB buffers for loading prerecorded raw audio data files. filBuf0 though filBuf6 are seven buffers in the DSP memory map that must be loaded with the prerecorded raw data. The global addresses of these files are given in the project map file.

To manually load the prerecorded raw-audio-data files:

1. Open CCS, and connect to the DSP target.
2. Select the DSP core, and load the out file executable.
3. Before starting execution, open a memory browse window (from the debug perspective view tab).
4. Right-click in the memory window, and choose *Load Memory*.
5. A dialog window will open. Fill out the required information (file name, attributes, and memory

address).

6. Wait for the loading to complete, and load the next prerecorded raw audio data file.
7. Repeat until all eight files are loaded.

3.2.1.2.2 Using a General Extension Language (GEL) File

Information about GEL scripts is available from TI's GEL wiki page. The function `GEL_Memory_Load()` loads raw data file into the memory. Pages 12 through 28 of [Code Composer Studio User's Guide](#) defines how to use the `GEL_Memory_Load` function.

The GEL file `files_io_7.gel` from directory `C:\ti\processor_sdk_rtos_omap137_xx_xx_xx_xx\demos\audio-preprocessing\file_demo_bios\omap137` contains instructions to load TI Design example audio files (which reside in subdirectory `common\t8`) into the core memory. To load a different set of audio files the user can modify the `files_io_7.gel` file.

注: The audio files are binary files in raw format. The user must verify that the directory and names of the audio files in the GEL are correct. See *Processor SDK RTOS Audio Pre Processing* [1] for information to use the GEL file.

3.2.1.3 Changing the Beamforming Structures for Different Geometry

注: The following is only relevant if the user wants to change any of the parameter in the `OMAPL137_bf_rt` project, such as the number of microphone and the geometry of the microphone array, the number of virtual microphones, or sampling rate. Any of these changes requires recalculating of the filter coefficients and rebuilding of the project with the new coefficients as described in 节 3.2.1.1.

Before downloading a non-default set of filter coefficients, the user should update the beamforming configuration structures. In the expression window of the debug perspective, write `sysConfig` (see 图 15) and configure the following parameters (all other parameters must remain as default):

- `nmics` is the number of microphones or raw-data audio files. This value is set depending on the number of files used.
- `nvmics` is the number of virtual microphones. The default value is eight, which represents the eight directions that the MSS looks at; that is, there are eight systems of beamforming (BF) and ASNR. Each system represents a different direction, and the MSS chooses the best one. The user can choose a different number of virtual microphones.
- The second structure is `bfConfig`. The sampling rate value of one translates into 8000 samples per second. The sampling rate value of two translates into 16000 samples per second.
- The value of `num_mics` is the number of virtual microphones that are connected to the MSS algorithms, which is the same as in `sysConfig`.
- The value of `bf_type` describes the type of BF calculations. This value can be either fixed-point short (`bf_type = 1`) or float (`bf_type = 2`). 图 15 shows the fixed-point algorithm option.

▲  sysConfig	struct sysConfig_stc	{...}
(x)= nmics	short	8
(x)= nvms	short	4

(x)= bf_type	short	1

图 15. Setting sysConfig and bfConfig

3.2.1.4 Changing the Filter Coefficients

The beamforming filter coefficients depend on the geometry of the microphone array. The synthetic, raw audio data files that are part of this project in directory `C:\ti\processor_sdk_rtos_omap137_xx_xx_xx_xx\demo\audio-preprocessing\common\t8` were generated under the assumption that the microphones are along a circular array of seven microphones. The filter coefficients in the this project were calculated accordingly. Should the user wish to use a different microphone array or use prerecorded raw data recorded from microphones in a different geometry, new filter coefficients are necessary. 节 3.2.1.5 describes how to calculate a new set of filter coefficients for the geometry of the microphone array. The new filters' coefficients buffers are updated and the project should be rebuilt. See *Processor SDK RTOS Audio Pre-Processing* [1] for instructions to add new filter coefficients.

3.2.1.5 Calculating Filter Coefficients

As was stated in 节 3.2.1.4, the beamforming filter coefficients depend on the geometry of the microphone array and the angle of the direction of the source with respect to the microphone array. `bfgui.exe` is a tool to generate beamforming filter coefficients and is part of the AER library in directory `AER\AER_64\tools\bf_tool` (AER is the directory where the user installed the AER library). A user's guide for the beamforming design tool `bfgui.pdf` is in the same directory as well. The user is strongly encouraged to read `bfgui.pdf` because it gives insight into the general theory of beamforming.

Upon starting `bfgui.exe`, the user should configure the following values, as shown in 表 4.

表 4. Beamforming Design Tool Values

VALUE	COMMENTS
Sampling rate (KHz)	This TI Design uses 16 (16000). The default value of the tool is 8000.
Number of microphones	For using CMB (the real-time project), seven microphones are used. The offline project uses eight microphones.
Microphone distance	Distance in centimeters between two adjacent microphones. Equal distance between any two microphones is assumed. For linear array, it is the linear distance, and for circular array, it is the linear distance of the chord between two microphones.
BF angle	The utility generates a set of filters for a single angle of arrival; that is, for a single directional virtual microphone. For a system with multiple directional virtual microphones like the one that is used in this TI Design, the utility must be called multiple times, each time for a different angle. The real-time project defines eight directional virtual microphones for the following angles: 0°, 45°, 90°, 135°, 180°, 225°, 270°, and 315°.
Geometry	Microphone array geometry: 0 for 1D linear, 1 for 2D linear, 2 for 2D rectangular, and 3 for circular. Using CMB requires geometry be set to 3.
Contour levels	Required for graphical illustration. Leave as default.
Polar frequency	Required for graphical illustration. Leave as default.

The number of virtual-directional microphones was set to eight so that every 45° (360° divided by 8) is a virtual-directional microphone. The trade-off is the more virtual-directional microphones, the better the focus on the desired audio source and better elimination of undesired sounds and clutter noises. On the other hand, the processing load of the beamforming and the ASNR depends linearly on the number of virtual-directional microphones.

Following the instructions in the user's guide (bfgui.pdf), configure the filter coefficients tool for eight microphones with circular geometry with 3-cm equal distance between any two microphones. This filter is for 45° of arrival. 图 16 shows the configuration of the filter generation tool. The filter coefficients are stored in filterCoeff.log.

图 16. Configuration of Filter Generation Tool

3.2.1.6 Modifying the Microphones for audioAnalogLoopbackTest

The microphones in the CMB are sampled 16000 times a second and 24-bit padded in 32-bit (4 bytes) each sample. The eight microphones are interleaved and sent through a McASP port to the C6747.

When the streaming data accumulates 10 ms of data, the C6747 DSP starts processing the data. In 10 ms each microphone samples 160 times, so the total size of the processing buffer is 1280 (160 × 8), 32-bit values or 5120 bytes.

The file mcasep_cfg.c in directory

`SDK_DIRECTORY\pdk_omap137_1_0_1\packages\ti\addon\cmb\test\evmOMAPL137\analog\loopback\src` (SDK_DIRECTORY is the directory where Processing SDK was installed) controls the internal C6747 stream connection. The BUFLen value represents the number of samples from two microphones in 10-ms frame, that is 320 samples. BUFSIZ represents the number of bytes in the two microphones in 10 ms, which is 320 × 4. The pointer tempRxPtr points to the current streaming data. The eight microphones are interleaved in the following way:

- BUFLen 32-bit words of microphone one and microphone two interleaved; that is, first value microphone one, first value microphone two, second value microphone one, and so on.
- BUFLen 32-bit words of microphone five and microphone six interleaved; that is, first value microphone five, first value microphone six, second value microphone five, and so on.
- BUFLen 32-bit words of microphone four and microphone three interleaved; that is, first value microphone four, first value microphone three, second value microphone four, and so on.
- BUFLen 32-bit words of microphone eight and microphone seven interleaved; that is, first value microphone eight, first value microphone seven, second value microphone eight, and so on.

The pointer tempTxPtr points to the stream that is sent to the onboard codec. The left and right channels of the codec are interleaved as follows: first left channel, first right channel, second left channel, second right channel, and so on.

The code that copies data from tempRxPtr to tempTxPtr starts at line 546 of mcasp_cfg.c (in the current release; this may change for future releases) where there is a for loop that loops BUFLen two times. The memcpy instruction copies one 32-bit (4 bytes) value from the tempRxPtr to tempTxPtr. The following illustrates how to choose the output microphones.

3.2.1.6.1 Connecting the Left-Channel Linked Microphone

The first memcpy in the for loop copies a microphone stream that is linked to the left channel of the onboard codec. The source code specifies multiple microphones streams. The user should comment out all memcpy except the one microphone that will be linked to the left channel of the codec. The default microphone is microphone number one.

Following the change of a microphone, the project must be rebuilt.

3.2.1.6.2 Connecting the Right-Channel Linked Microphone

The second memcpy in the for loop copies a microphone stream that is linked to the right channel of the onboard codec. The source code specifies multiple microphone streams. The user should comment out all memcpy except the one microphone that will be linked to the right channel of the codec. The default microphone is microphone number eight.

Following the change of a microphone, the project must be rebuilt.

3.2.1.7 Benchmarks

表 5 shows a summary of the necessary MIPS-count measurements for offline calculations of beamforming where the sampling rate is 16 KHz, 16-bits for a sample. Two configurations were benchmarked: 8 virtual microphones (45° apart) and 12 virtual microphones (30° apart).

表 5. MIPS Count Summary

SYSTEM CHARACTERISTICS	MIPS
OMAP-L137 SK 8 virtual microphones	40 MIPS
OMAP-L137 SK 12 virtual microphones	60 MIPS

3.2.2 Test Results

图 17 和 图 18 显示运行演示并捕获干净和不清音频从线入到 PC 与 Audacity。左声道是干净和右声道不清。

如果一个系统被设计具有语音识别引擎，干净的音频将被输入到该引擎。进一步的频谱分析可以在结果上执行以评估在最终设计调音过程中过滤的频率类型。
